The artichoke plume moth and other pests injurious to the globe artichoke, W. H. LANGE, JR. (*California Sta. Bul.* 653 (1941), pp. 71, figs. 30).—Three overlapping generations of the artichoke plume moth occur annually in the coastal artichoke-growing areas of California, and all stages of this pest may be found during every month of the year. Oviposition occurs chiefly at night, and eggs are usually deposited singly and externally among the woolly hairs on the under side of the leaves. The time from egg deposition until emergence of the adult varied from 80 to 110 days. During the earlier stages the larvae feed on the tender interfolded leaves but later bore inside the leaf stalks or floral heads. Pupation usually occurs in the larval burrows inside the leaf stalks or on the outer bracts of the floral heads.

The parasite *Angitia platyptiliae* Cushman, parasitized from 2 to 90 percent of artichoke plume moth larvae during the period from 1936 to 1939. Predators noted include Staphylinidae larvae, spiders, mites, and the cliff swallow (*Petrochelidon lunifrons*).

Chemical control measures and light traps were not practical controls. Placing cut tops in ditches and covering with soil and burning plants shortly after cutting were found useful for the destruction of this insect.

Other pests mentioned as being associated with artichokes included the calendula plume moth *Platyptilia williamsii* Grin., several species of the genus *Oidaematophorus*, the artichoke aphid *Capitophorus braggii* (Gil.), bean aphid, ragwort or cineraria leaf miner *Phytomyza atricornis* Meig., greenhouse leaf tier, scabby sowbug *Porcellio scaber* Latr., *Lygus sallei* Stål, *Irbisia solani* Heid., *Peritelopsis globiventris* (Lec.), *Diabrotica 11-punctata* (Mann.) (sister Lec.), *Embolocia sausalitae* (Grt.), *Choreutis melanifera* Kelfer, corn earworm, salt-marsh caterpillar, *Sabulodes caberata* Guen., painted lady, several tortricid larvae as well as other lepidopterous larvae, the thistle crown fly *Cheilosia baroni* Williston, *Paracantha culta* (Wied.), rodents, and slugs and snails. Mention is also made of the plant diseases affecting the artichoke, and a tabulation of all insects collected on the plant is included.

[Contributions on orchard pests] (*Md. Agr. Soc., Farm Bur., Rpt.*, 25 (1940), pp. 137-146, 155-161).—Contributions presented in this report are: New Methods of Codling Moth Control, by C. Graham (pp. 137-141); What Can the Orchardist do to Combat the Japanese Beetle? by G. S. Langford (pp. 141-144) (Univ. Md.); The European Corn Borer, by E. N. Cory (pp. 144-146) (Md. Expt. Sta.); and Using the New Methods for Peach Borer Control, by O. I. Snapp (pp. 155-161) (U. S. D. A.).

Methods used in rearing small insects infesting stored food products. N. E. HICKIN (*Roy. Ent. Soc. London, Proc., Ser. A*, 16 (1941), No. 4-6, pp. 35-38, figs. 4).

Avian hosts for malaria research, F. WOLFSON (*Quart. Rev. Biol.*, 16 (1941), No. 4, pp. 462-473).—It is concluded that of the four avian hosts available for malaria research in the United States (canary, chicken, pigeon, and duck), the duck is the most suitable. "Like the canary, the duck is susceptible to several species of *Plasmodium*, each of which produces a sufficiently severe and lasting infection to be useful for laboratory study. The chief advantages of the duck over the canary are its large size, low cost, and adequate supply. Unlike the duck, the chicken and pigeon are each susceptible only to one species of *Plasmodium* available in this country. Moreover, even *P. lophurae* produces a more severe and lasting infection in the duck than it does in the chicken. The vectors of *Plasmodium* residing in the pigeon are unknown, whereas the vectors of at least three species of *Plasmodium* residing in the duck are known. Only duck embryos are thus far known to be susceptible to species of *Plasmodium*

available in this country. Peking ducks are grown commercially in this country on a large scale. They can be bred throughout the year even on small general farms. The normal blood picture of ducks has been investigated and reported. The maintenance of ducks and duck embryos in the laboratory presents no difficulty. *Plasmodium* in duck tissues can be maintained successfully in culture." A list is given of 39 references to the literature.

**Insect control important in increased crop production**, G. F. KNOWLTON (*Farm and Home Sci. [Utah Sta.]*, 2 (1941), No. 4, p. 9, figs. 2).—A practical discussion.

**Resistance of plants to insect attack**, R. O. SNELLING. (U. S. D. A., Ill. Expt. Sta., et al.). (*Bot. Rev.*, 7 (1941), No. 10, pp. 543-586).—The subject matter of this monographic review (567 references) considers records and importance of host resistance, plant characteristics suggested as having an influence in resisting insect attack, and breeding plants to reduce insect damage, in each case with accompanying tabulated data.

**Are population oscillations inherent in the host-parasite relation?** P. DE BACH and H. S. SMITH. (Calif. Citrus Expt. Sta.). (*Ecology*, 22 (1941), No. 4, pp. 363-369, fig. 1).

**The effects of hosts upon their insect parasites**, G. SALT (*Biol. Rev. Cambridge Phil. Soc.*, 16 (1941), No. 4, pp. 239-264, figs. 6).

**The history of insecticides arranged as a chronological table**, H. H. SHEPARD. (Minn. Expt. Sta.). (*Pests*, 9 (1941), No. 12, pp. 12-13).

**Studies of contact insecticides**.—XV, An insect toximeter, W. C. O'KANE, L. C. GLOVER, and R. L. BLICKLE (*New Hampshire Sta. Tech. Bul.* 76 (1941), pp. 10, figs. 4).—In continuation of these studies (*E. S. R.*, 84, p. 360), a turntable apparatus, insect-holding device, and atomizers for spraying insects are described which assure even application on each individual insect and on all sides of the insects. The procedure for using this toximeter and parts is discussed, as well as specifications and plans for building it.

**Problem of insecticide spray residue**, A. J. COX (*Amer. Jour. Pub. Health*, 31 (1941), No. 11, pp. 1163-1168).

**Spray retention: Amounts of arsenic and sulphur retained employing spray compositions**, F. A. HERMAN (*Canad. Chem. and Process Indus.*, 25 (1941), No. 10, pp. 526-527, fig. 1).

**The effect of carbon bisulphide on the germination of paddy**, G. STAHEL (*Trop. Agr. [Trinidad]*, 18 (1941), No. 10, pp. 200-203).—Experiments are reported which show that the poisonous effect of carbon bisulfide vapor, used as an insecticide, on the germination of seed paddy depends closely on the water content of the latter, at least when it is between 9 and 16.5 percent. Air-dried paddy of 14 percent moisture content may be treated with the usual carbon bisulfide concentration for disinfecting purposes as long as 7 days without doing harm to germination. With 13 percent moisture content, even a 14 days' treatment is not harmful. Very dry paddy below 9 percent still germinates after a 14 days' treatment with saturated vapor or even with liquid carbon bisulfide.

**Investigations on controversial points of fumigation methods**, D. L. LINDGREN. (Univ. Calif.). (*Citrus Leaves*, 21 (1941), No. 7, pp. 5-6, 27).

**Ability of the firebrat to damage fabrics and paper**, J. AUSTIN and C. H. RICHARDSON. (Iowa Expt. Sta.). (*Jour. N. Y. Ent. Soc.*, 49 (1941), No. 4, pp. 357-365).—Report is made of an investigation of damage by the firebrat to 25 fabrics of 7 fibers (cotton, jute, linen, ramie, rayon, silk, and wool) and to three papers (two low ash filter papers and one medium typewriter bond). Medium typewriter bond paper, regenerated cellulose, either knitted or plain weave, and linen were the materials most heavily damaged. Cotton and silk were attacked if the

texture of the material was very suitable for feeding. The typewriter bond was the only one of the three papers tested that was seriously damaged. The significance of the ability of the firebrat to survive on these materials was tested statistically by comparing data for the survival period on the material with the survival data for the corresponding starvation control. The differences in the mean survival periods were significant for knitted regenerated cellulose and medium typewriter bond paper.

**Barium compounds as poisons in firebrat baits,** C. H. RICHARDSON and E. G. SEIFERLE. (Iowa Expt. Sta.). (*Pests*, 9 (1941), No. 9, pp. 22-25, fig. 1).—In experiments in which 26 barium compounds in a food mixture at 4 percent concentrations were tested for mortality to the firebrat 17 proved to be nontoxic or produced mortalities in 96 hr. of less than 25 percent. The most toxic compounds were barium fluosilicate and barium carbonate, followed by barium oxalate and then by barium peroxide and barium triphosphate. Description is given of a practical bait containing barium carbonate as the toxic ingredient.

**Laboratory technique for the study of living termites,** A. M. ADAMSON (*Ecology*, 22 (1941), No. 4, pp. 411-414).

**Dinitro-ortho-cresol and other insecticides as locust poisons: Experiments of 1938-39,** M. C. A. NOLTE (*Union So. Africa Dept. Agr. and Forestry, Sci. Bul.* 232 [1941], pp. 55).—This report relates to baiting, dusting, and spraying tests carried out in the laboratory and in the field with various materials, chiefly with preparations which contain 4,6-dinitro-*o*-cresol as the active principle, and with a few proprietary insecticides. Dusting tests showed that two proprietary insecticides (No. 3436 and K.3) as well as various dusts with 4,6-dinitro-*o*-cresol as the active principle were all particularly effective against both the red locust *Locustana pardalina* (Walk.) and the brown locust *Nomadacris septemfasciata* (Serv.) in the hopper as well as in the flying stage. The dosage per acre which was necessary to give favorable results varied according to circumstances and the method of application. The conclusion is that 30 lb. per acre of any of these dusts is sufficient to cause effective destruction of locust swarms, provided it is dusted evenly over the whole surface, e. g., by means of a cloud of dust which spreads out evenly. The most satisfactory and economical method of application appears to be by means of airplane dusting. Recommendations have been made for a large-scale experiment by means of airplanes. With a thorough, even distribution of the powder it is probable that less than 30 lb. (e. g., 20 lb.) per acre may prove to be adequate.

**Grasshoppers and their effect on sagebrush on the Little Powder River in Wyoming and Montana,** B. W. ALLRED. (U. S. D. A.). (*Ecology*, 22 (1941), No. 4, pp. 387-392, figs. 3).

**The relation of temperature to the embryonic and nymphal development of the differential grasshopper (*Melanoplus differentialis* Thomas),** M. H. SWENK and C. H. BRATT (*Nebraska Sta. Res. Bul.* 122 (1941), pp. 24, figs. 9).—Temperatures from 80° to 85° F. were found the most favorable for successful development of eggs of the differential grasshopper. When high hatching percentage and rapid egg development were considered, 80° represented the optimum incubation temperature. Nymphal development varied directly with the temperature. Nymphs were sluggish at 60° and did not feed and failed to develop beyond the first instar. At 65° some nymphs fed and one reached the fourth instar, at 70° some reached the adult stage, and at 75° a fair number became adults. Development was completed in 48.5, 39.9, and 34 days at 80°, 85°, and 90°, respectively. Although there are normally six nymphal instars, a total of seven or eight were noted in several instances with temperatures of 85° or higher.

The plant bugs, or Miridae, of Illinois, H. H. KNIGHT (*Ill. Nat. Hist. Survey Bul.*, 22 (1941), Art. 1, pp. [6]+234, figs. 182).—This contribution deals with plant bugs of the family Miridae, which contains more than a third of the species of the order Hemiptera. Except for a few predaceous forms, they suck the juices from plant leaves and, with the leafhoppers, aphids, and scale insects, rank as one of the most important groups of plant-sucking insects in Illinois. Four hundred and forty species are treated, of which 110 are extralimital species, forms known from the entire general region in which Illinois is situated being included. Nineteen species are described as new.

Following a foreword by T. H. Frison and a brief introduction, the biology (pp. 2-5), distribution and habitat preference (pp. 5-12), economic status and control (pp. 12-15), and taxonomy (pp. 15-210) are dealt with. A host list (pp. 211-217), bibliography of five pages, and an index are included.

Notes on the orchid bug *Mertila malayensis* Distant on white mariposa (*Phalaenopsis amabilis* Blume), S. R. CAPCO (*Philippine Jour. Sci.*, 75 (1941), No. 2, pp. 185-195, pls. 2).—The capsid bug pest *M. malayensis*, which attacks the leaves, peduncles, and roots of orchid plants and especially *P. amabilis*, causing great damage, is recorded for the first time in the Philippines. It has been reported from Singapore, Burma, Bhamo, Java, Dutch East Indies, and India and to have been introduced into Germany. Feeding and oviposition punctures are responsible for the injury to the plants, causing the badly infested leaves to dry up and fall off.

Two approaches to the control of the potato leafhopper—insecticidal and varietal resistance, J. P. SLEESMAN. (*Ohio Expt. Sta.*). (*Ohio Veg. and Potato Growers Assoc. Proc.*, 26 (1941), pp. 74-76, 78).

The control of potato aphids on Long Island, J. O. NOTTINGHAM and W. A. RAWLINS. (*Cornell Univ.*). (*Amer. Potato Jour.*, 18 (1941), No. 11, pp. 305-311, fig. 1).—The use of nicotine spray and nicotine vapor has given excellent control of the potato aphid and the green peach aphid, which have frequently infested potato plantings on Long Island.

Yellow dwarf of tobacco in Australia.—II, Transmission by the jassid *Thamnotettix argentata* (Evans), A. V. HILL (*Jour. Council Sci. and Indus. Res. [Austral.]*, 14 (1941), No. 3, pp. 181-186).—Experiments have shown *T. argentata* to be a vector of yellow dwarf, a virus disease of tobacco in Australia. The minimum incubation period of the disease in the plant is 10 days.

A classification of the scale insect genus *Asterolecanium*, L. M. RUSSELL (*U. S. Dept. Agr., Misc. Pub.* 424 (1941), pp. 322, pls. 9, figs. 84).—The economic importance, geographical distribution, host associations, relationships, synonymy, characters used in classification, and species groups of the scales of the genus *Asterolecanium* are discussed. The genus, 83 new species, and all previously described species considered valid by the author are characterized. Mention is made of the 17 species unknown to the author. Keys are included to larvae and adult females. Photographs and drawings supplement the descriptive matter. One hundred references to the literature are cited.

Progress of the control of coconut-feeding Coccidae in Seychelles, D. VESEY-FITZGERALD (*Bul. Ent. Res.*, 32 (1941), No. 2, pp. 161-164).

Derris root infusion for sucking and biting lice of mammals, R. B. GAPUZ (*Philippine Jour. Anim. Indus.*, 8 (1941), No. 4, pp. 389-393).—Infusions of crushed dry roots of *Derris* sp. varying in concentration from 0.6 to 5 percent were very effective for the destruction of sucking lice of carabaos and cattle. An infusion of crushed fresh roots of *D. philippinensis* with a strength of 2.5 percent, i. e., 250 gm. of crushed fresh roots steeped in 10 l. of water, was effective against biting lice of horses.

**An ecological study of the forest tent caterpillar (*Malacosoma disstria* Hbn.) in northern Minnesota**, A. C. HOBSON (*Minnesota Sta. Tech. Bul.* 148 (1941), pp. [1]+55, figs. 6).—This report reviews outbreaks of the forest tent caterpillar in the United States and Canada, with particular reference to those since 1917. Recent outbreaks in Minnesota are described in detail. Hatching occurs from May 5 to 25. From 5 to 6 weeks elapse from the hatching date to the appearance of cocoons. The prepupal stage lasts about 2 days and the pupal from 8 to 12 days. Moths were active in the field for about 2 weeks (July 5–20). The quantity of food eaten during larval development and the production of frass are discussed. It is pointed out that frass collections might be used for the determination of populations. Larvae were unable to pupate when without food during the last instar. Adult females that developed from larvae which fed half the usual feeding time during the last instar contained an average of 97 eggs as compared with 172 for controls. Methods for estimating populations are described. Samples of egg bands were found valuable in measuring the total population in an area. No single natural factor was found entirely responsible for reduction in numbers of forest tent caterpillars. For example, in one area high summer temperature was important, in another spring frost was destructive, and in the third parasites exhibited an unusual degree of efficiency. Other factors contributed in all cases. Some possible regulating factors influencing the cyclic behavior of populations and a theory of the possible origin of parallel fluctuations in numbers in separate localities are mentioned.

**Two new methods of trapping the cacao [almond] moth (*Ephestia cautella*)**, F. D. GOLDING (*Bul. Ent. Res.*, 32 (1941), No. 2, pp. 123–132).

**Revision of the North American moths of the family Oecophoridae, with descriptions of new genera and species**, J. F. G. CLARKE (*U. S. Natl. Mus. Proc.*, 90 (1941), No. 3107, pp. 33–286+VIII, pls. 48).—This is a revision of a family (Oecophoridae) that comprises a large group of small to medium-sized moths, most of which are inconspicuously colored but a few are brilliantly marked. The majority of the forms are leaf and flower feeders in the larval stage, and those that feed in the inflorescence usually attack plants of the family Umbelliferae, while the leaf feeders attack a large variety of plants in many families. Some are forest pests. Aside from these leaf and flower feeders, there are others that feed on stored products such as dried foods, bulbs, and tubers. Some are scavengers and feed in the refuse occurring in the nests of mice and birds. Some live in the cracks of bark, others beneath the bark where they feed either on refuse or bits of dried vegetable matter. One (*Martyrhilda phaealocae* n. sp.) is a leaf miner. Twenty-two genera and 117 North American species are recognized, of which 6 genera are erected and 19 species and 1 race described as new.

**The sugarcane borer**, J. W. INGRAM and E. K. BYNUM (*U. S. Dept. Agr., Farmers' Bul.* 1884 (1941), pp. 11+17, figs. 5).—The latest available information on sugarcane borer control is summarized in this publication. Practical control measures suggested include: Clean up pieces of millable cane during harvesting operations to eliminate overwintering borers; burn trash and large grasses as soon as these are sufficiently dry after harvest; cut low when harvesting cane to decrease number of borers overwintering in cane stubs; if possible, flood fields for 3 or 4 days after harvest; select seed cane free from borers when possible; soak seed cane 72 hr. before planting when practical; if agronomically practical, plant resistant variety Co. 290 in areas of heavy infestation and refrain from planting susceptible varieties, C. P. 29/116 and C. P. 29/108.

A summary of recent investigations of sugarcane borer control with cryolite and other insecticides, J. W. INGRAM and A. L. DUGAS. (U. S. D. A. coop. La. Expt. Sta.). (*Sugar Bul.*, 20 (1941), No. 4, pp. 27-29).

Two new species of cecidomyiid flies from phlox, C. T. GREENE (*U. S. Natl. Mus. Proc.*, 90 (1941), No. 3120, pp. 547-551, fig. 1).—*Hyperdiplosis phlox* and *Leotodiplosis maculipennis*, both reared at the Ohio Experiment Station from phlox that had been severely damaged, are described as new. It is pointed out that in experiments conducted by C. R. Neiswander with phlox the former was found to be responsible for the injury, but that *L. maculipennis* is undoubtedly a predator on *H. phlox*.

New Jersey Mosquito Extermination Association, twenty-seventh [and twenty-eighth annual meetings held at Atlantic City, N. J.] (*N. J. Mosquito Extermin. Assoc. Proc.*, 27 (1940), pp. [2]+203+[3], pls. 9, figs. 10; 28 (1941), pp. 211+[3], pls. 8, figs. 13).—Among the contributions presented at the twenty-seventh meeting (E. S. R., 82, p. 653) held in March 1940 are the following: The Relation of Mosquitoes to Diseases of Man and Animals in New Jersey, by T. J. Headlee (pp. 5-11) (N. J. Expt. Stas.); The Relation of Mosquitoes to Equine Encephalomyelitis in Massachusetts, by P. J. Jakmauh (pp. 12-18); A Review of Contributions Made Throughout the World in 1939 to the Knowledge of Mosquitoes, by F. C. Bishopp and J. L. Webb (pp. 19-35) (U. S. D. A.); Control of Mosquitoes at the New York World's Fair, by J. G. Grimley and H. L. Felton (pp. 102-105); and Tidal Inundation as a Factor Limiting the Distribution of *Aedes* spp. on a Delaware Salt Marsh, by W. A. Connell (pp. 166-177) (Del. Sta.).

Among those at the meeting in March 1941 are the following: New Jersey Mosquito Problems, by T. J. Headlee (pp. 7-12). Distribution of *Aedes vexans* Eggs, by C. Filsinger (pp. 12-19). Studies of the Effect of Reduction of Surface Tension on Mosquito Pupae, by M. A. Manzell (pp. 19-23). Mosquito Control in New Jersey in 1940 and Its Contributions to National Defense, by T. D. Mulhern (pp. 72-114), and The Present Status of Knowledge on Mosquito Oils and Larvicides, by J. M. Ginsburg (pp. 135-143) (all N. J. Stas.); A Review of Contributions to Knowledge of Mosquitoes During 1940, by F. C. Bishopp and J. L. Webb (pp. 24-38), and Comparative Resistance of Several Species of Mosquitoes to Larvicides (pp. 119-126) and Factors That May Affect the Toxicity of Pyrethrum-Oil Emulsions as Mosquito Larvicides (pp. 127-135), both by H. H. Stage and W. W. Yates (all U. S. D. A.); A Brief Account of the Malaria Epidemic at Ithaca (1904-1907), by R. Matheson (pp. 162-165) (Cornell Univ.); Mosquito Suppression Work in Canada in 1940, by A. Gibson (pp. 167-176); *Mansonella perturbans* (Walk.) on Cape Cod, by R. L. Armstrong (pp. 184-188); and Report on the Delaware County Mosquito Extermination Commission for 1940, by J. F. Conner and J. H. Spackman (pp. 201-204).

Flies as carriers of poliomyelitis virus in urban epidemics, A. B. SABIN and R. WARD (*Science*, 94 (1941), No. 2451, pp. 590-591).—In the search for carriers of the poliomyelitis virus under way but not completed, three positive findings have been obtained with flies caught during outbreaks—two from lots representing several species caught in urban sites in Cleveland, Ohio, and one with a small number of flies caught in Atlanta, Ga. This confirms the finding of Paul and his associates (E. S. R., 86, p. 362).

Seasonal occurrence and the effect of host attractiveness on the abundance of stable flies and horn flies on cattle, T. H. MAILEN. (Okla. A. and M. Col. et al.). (*Okla. Acad. Sci. Proc.*, 21 (1941), pp. 19-21, fig. 1).—Field experiments indicate that on account of the extreme variation in the attractiveness of different animals to stableflies and hornflies and also additional evidence of

the difference in attractiveness of a single animal at different periods it is impossible to use unsprayed animals as checks in determining the effects of fly sprays.

**Siphonaptera:** The genera *Amphalius* and *Otenophyllus* in North America, W. L. JELLISON (*Pub. Health Rpts. [U. S.]*, 56 (1941), No. 49, pp. 2341-2349, figs. 2).—Two genera of fleas that are characteristic parasites of pikas (*Ochotona* spp.), which include the smallest members of the order Lagomorpha, are considered.

**The Japanese beetle problem, especially as it affects the vegetable industry,** J. W. BARRINGER (*Ohio Veg. and Potato Growers Assoc. Proc.*, 25 (1940), pp. 67-74).

**Tasmanian grass-grubs,** J. W. EVANS (*Tasmania Dept. Agr. Bul.* 22, n. ser. (1941), pp. 23, figs. 7).—Three species of grass grubs of the lepidopterous genus *Oncopera* that are pasture pests in Tasmania are considered, namely, *O. intricata* Walk., *O. rufobrunnea* Tindale, and *O. intricoides* Tindale, of which the last two mentioned also occur on the Australian mainland. The larvae are subterranean and feed at night on surface vegetation.

**Studies in population physiology.—X, Interspecific competition in populations of granary beetles,** T. PARK, E. V. GREGG, and C. Z. LUTHERMAN (*Physiol. Zool.*, 14 (1941), No. 4, pp. 395-430, figs. 1).—In further work (E. S. R., 82, p. 83) in which the authors attempted to analyze experimentally the effect of interspecific competition on population growth, *Tribolium confusum*, *Gnathocerus cornutus*, and *Trogoderma versicolor* were used. The following general conclusions describing the end result of the competition are listed: "If *Tribolium* gets well established as a population it drives out *Gnathocerus*. If *Tribolium* populations are reduced to a low point by some type of epidemic infection (or, presumably, some other mechanism), *Gnathocerus* gets the upper hand and *Tribolium* becomes extinct. *Tribolium* always drives out *Trogoderma*, irrespective of initial imaginal densities. *Gnathocerus* usually drives out *Trogoderma*. This is true if the former is seeded initially in equal or higher densities. *Trogoderma* is the winner when started in a higher density than *Gnathocerus*." A list of 22 references is included.

**Losses of bees from poisons in Utah,** J. I. HAMBLETON (*Gleanings Bee Cult.*, 69 (1941), No. 11, pp. 685, 731).

**Moth pests of honeybee combs,** V. G. MILUM. (Univ. Ill). (*Ill. State Beekeepers' Assoc. Ann. Rpt.*, 40 (1940), pp. 113-128, figs. 9).

**The wheat jointworm in Oregon, with special reference to its dispersion, injury, and parasitization,** T. R. CHAMBERLIN (*U. S. Dept. Agr., Tech. Bul.* 784 (1941), pp. 48, figs. 6).—This discusses the biology, parasitization, injury, control, and dispersion of the jointworm in the Willamette Valley of Oregon. First found in 1926, original infestations were heavy but had declined to 3 percent or less by 1934. The average yearly spread was slightly more than a mile. Adults emerged from stubble between April 5 and May 19. Eggs were largely deposited in the second and third joints of wheat. Fall and winter or early wheats were preferred for oviposition. It was estimated that each female had an average capacity of 90 eggs. Females constitute approximately 60 percent of the population. Jointworms reduced the size and number of kernels per head.

Parasitization studies indicated that if parasites reduced the theoretical effective rate of reproduction from 54 to 1 to 35 to 1 or less, other factors were sufficient to put the jointworm population on a descending scale. Parasites discussed included *Eurytoma parva* Phillips, *Ditropinotus aureoviridis* Cwfd.,

*Eupelmella vesicularis* (Retz.), *Eupelmus allynii* (French), *Calosota metallica* Gahan, *Decatoma amsterdamensis* Gir., and *Eurytoma phoebus* Gir.

Most jointworms in fall-buried stubble in the Willamette Valley die before the normal emergence period. It is pointed out that the planting of red clover in winter barley or winter oats rather than wheat permits farmers to plow under wheat stubble. Wheat should be planted as far as possible from the old stubble in those instances where this has not been plowed. Controlled burning of wheat stubble kills many jointworms.

New braconid parasites of *Antestia lineaticollis* Stål and of *Sylepta derogata* F., (I. E. J. NIXON (*Bul. Ent. Res.*, 32 (1941), No. 2, pp. 93-101, figs. 19).—Of the seven African forms of the genus *Aridelus* (*Helorimorpha*), including one species described as new, three are parasites of the important hemipterous coffee pest *A. lineaticollis*. The genus *Benama*, of which *B. hutsoni* n. sp., probably belonging to the subfamily Diospilinae, is the type, is erected. This new species is a parasite of the cotton leaf roller *S. derogata*.

## ANIMAL PRODUCTION

Nutritive value for ruminants of proteins in common feeding stuffs, F. B. MORRISON and J. I. MILLER. (Cornell Univ.). (*Internatl. Rev. Agr. [Roma]*, 32 (1941), No. 9, pp. 303T-309T).—Either the requirements of ruminants for essential amino acids differ from those of nonruminants or the ruminants have the ability to synthesize essential amino acids. These conclusions were derived from the completeness of certain plant proteins for ruminants as contrasted with nonruminants. Although urea nitrogen as practically the sole supply of nitrogen promoted little gain in lambs, it maintained a positive nitrogen balance. Hasty legislation to permit the use of urea in mixed feeds was not recommended. Little difference was found in the biological values of proteins from raw and heated soybean meal for lambs as contrasted with nonruminant studies. In feeding experiments it seemed important to furnish a good-quality protein to high-producing milk cows if maximum production is to be maintained.

The carotene content of certain species of grassland herbage, A. M. SMITH and T. WANG (*Jour. Agr. Sci. [England]*, 31 (1941), No. 3, pp. 370-378, fig. 1).—Stage of growth was the predominant factor in determining both N and carotene in the 63 samples of white clover, orchard grass, ryegrass, and timothy examined. A relationship of N content to carotene was noted, and the carotene content increased with N fertilization. Except for ryegrass, there was more carotene in the leaves and stems than in the heads or flowers.

Mycostatic salts prevent mold growths on stored foods, W. L. MALLMAN. (Mich. Expt. Sta.). (*Food Indus.*, 13 (1941), No. 7, pp. 41-42, 54).—The use of salts for treatment of containers or wrappings for vegetables with substances inhibiting mold growth in storage, as in the case of eggs (*E. S. R.*, 84, p. 661; 86, p. 79), is suggested.

Inspection of feeds, E. J. DESZYCK, T. WRIGHT, JR., and R. L. SWALLOW (*Rhode Island Sta. Feeds. Cir.*, Sept. 1941, pp. 77).—The usual report on the guaranteed and found analyses of feed officially examined in connection with the Rhode Island feed law (*E. S. R.*, 84, p. 373).

The minimum base value of heat production in animals, E. B. FORBES and R. W. SWIFT. (Pa. State Col.). (*Science*, 93 (1941), No. 2426, pp. 623-624, fig. 1).—Dynamic effects of nutrients observed at planes of nutrition below that of energy equilibrium were shown by examples of heat production by steers to be fundamentally invalid. The heat production showed a nearly straight-line relation to dry-matter consumption above a minimum level.

**Izmerenie rosta i skorospelosti zbitovnykh** (Measuring of growth and early maturity in animals), N. N. KOLESNIK (*Akad. Nauk S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.)*, No. 13 (1940), pp. 5-42, figs. 7; *Eng. abs.*, pp. 40-42).—A mathematical consideration of growth and maturity in animals.

The relative net energy values of alfalfa hay and corn grain and of sorghum fodder and alfalfa hay as determined by feeding experiments with fattening lambs, F. H. LEINBACH (In *Cornell University Abstracts of Theses*, 1940. Ithaca, N. Y.: Cornell Univ. Press, 1941, pp. 419-421).—The net energy value of alfalfa hay and sorghum fodder fed in heavy, medium, and light rations with corn to groups of lambs in two experiments was calculated as 33.86 and 33.11 therms, respectively, per 100 lb. The need for a uniformity of finish of the livestock is emphasized if results of feeding experiments are to be used for determination of relative net energy values. The revised value for alfalfa was similar to that calculated from respiration calorimetric studies with cattle by Forbes et al. (*E. S. R.*, 62, p. 656).

The use of lamb fattening experiments in determining the relative net energy values of distillers' corn dried grains and brewers' dried grains in comparison with corn grain, G. M. CARRNS (In *Cornell University Abstracts of Theses*, 1940. Ithaca, N. Y.: Cornell Univ. Press, 1941, pp. 412-414).—Employing methods of Morrison (*E. S. R.*, 79, p. 664), the author found that the net energy values of distillers' corn dried grains and brewers' dried grains in comparison with shelled corn when calculated in two experiments with lambs showed sufficient differences to warrant repetition before drawing final conclusions.

Traits that determine the efficiency of the pig as a transformer of energy, E. G. RITZMAN and N. F. COLOVOS (*New Hampshire Sta. Tech. Bul.* 75 (1941), pp. 29, fig. 1).—The pig is shown to possess an extraordinary superiority over cattle and sheep in the proportion of digestible food energy that is stored. This was shown to be due to a more labile adaptation to environmental conditions. Data are presented in this study on the basal metabolism of 19 individual pigs ranging in age from 10 days to 3 yr. and from 3 to 200 kg. in weight with frequent comparisons with cattle and sheep reported in other studies. Basal metabolism studies showed that heat production of a boar was about 20 percent higher than that of two adult sows. By castration, heat production was reduced an average of 34 percent in the pig, as compared with 17 percent in sheep. Pregnancy and lactation in the sow increased the metabolism rate from 13 percent at 5.5 weeks of gestation to 76 percent 1 week after parturition. Seasonal variations were noted in the basal metabolism of the sow, so that there was a drop from about 18.4 calories per kilogram of weight per 24 hr. in the winter to below 15 in the hot summer months in spite of a uniform environmental temperature under which metabolism was ascertained.

Vitamin A and D and protein supplements for growing and fattening fall pigs in dry lot, L. E. HANSON (In *Cornell University Abstracts of Theses*, 1940. Ithaca, N. Y.: Cornell Univ. Press, 1941, pp. 417-418).—The standard ration of yellow corn and trio mixture was not improved in dry-lot feeding of swine by the addition of cod-liver oil or fortified cod-liver oil, suggesting that the ration was not deficient in vitamins A or D. Standard wheat middlings could be substituted for corn and tankage if the price differential made it worth while. Good alfalfa hay or some legume hay seemed essential for best results.

Riboflavin deficiency in the pig, A. J. PATEK, JR., J. POST, and J. VICTOR (*Amer. Jour. Physiol.*, 133 (1941), No. 1, pp. 47-55, figs. 2).—Pigs on a ration low in riboflavin developed characteristic changes of the eyes, coat, and gait and symptoms of anemia with ultimate collapse, all of which were prevented by supplementing the ration with 2.5 mg. daily of riboflavin per kilogram of weight.

The four pigs on the deficient ration consumed feed well until a day or two before collapse or death. Perhaps some of the changes observed in these animals, i. e., spastic paralysis, anemia, and possibly adrenal hemorrhages, resulted from a lack of other food products.

A study of the nutritional value of wheat germ products for swine, E. W. CRAMPTON (*Sci. Agr.*, 21 (1941), No. 12, pp. 750-758).—Supplementing the rations of eight sows with wheat germ during the latter part of the gestation period and lactation had no measurable influence on the birth or weaning weights of the pigs produced. Additions of wheat germ to the ration of fattening pigs caused an increase in the feed consumption of 8.5 percent and in live weight gains of 10 percent. Wheat-germ oil had no effect on growth of the pigs, and neither wheat product affected carcass quality.

Meeting the vitamin D requirement of pigs with alfalfa hay and winter sunshine, D. W. JOHNSON and L. S. PALMER. (Minn. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 63 (1941), No. 11, pp. 639-648).—A rachitic condition produced in pigs by including in the ration 5 percent of alfalfa hay containing 0.39 International Unit of vitamin D per gram was cured by a ration containing 5 percent of another alfalfa hay with 1.46 I. U. of vitamin D per gram. A ration containing 0.85 I. U. prevented but did not cure rickets. Rickets in pigs was cured by exposure to 45 min. per day to January or February sunshine for 2 weeks, although pigs fed indoors and allowed voluntary access to sunlight developed rickets. In arriving at the above conclusions, the authors conducted three experiments in feeding groups of pigs on normal swine rations containing 5 percent of alfalfa with irradiated and unirradiated yeast. The alfalfa hays contained 0.15, 0.39, 0.85, and 1.46 I. U. of vitamin D per gram. With the onset of rickets there was a decrease in the Ca per 100 cc. of blood plasma from about 11 to approximately 7 mg. The influence of varying amounts and ratios of Ca and P on the requirement of vitamin D was also investigated.

Jackstock production in Mississippi, R. H. MEANS (*Mississippi Sta. Bul.* 363 (1941), pp. 23, figs. 11; abs. in *Miss. Farm Res.* [Mississippi Sta.], 4 (1941), No. 10, pp. 3-6, figs. 11).—A brief account of jack production in Mississippi, including 4-yr. studies on costs, feed consumption, breeding, and growing the jacks and jennets. "The harvested feed cost of maintaining mature jennets for 1 yr. ranged from \$15 to \$25, depending upon the foaling date. The maintenance cost of jennets that foaled in the fall was considerably greater than for those that foaled in the spring. The jennets at breeding age represent a harvested feed cost of approximately \$35, with grain charged at \$1.50 per hundred and hay at \$10 per ton. The jacks produced in this study each consumed approximately 2.5 tons of grain and 2.75 tons of hay to breeding age or 3-year-olds. The harvested feed cost was slightly more than \$100 per jack. . . . The breeding records reported indicate that jennets are harder to get settled in foal than mares. Under the conditions of this experiment it was necessary to breed jennets on an average of 4.8 heat periods to produce one foal."

Canned fish as a meat substitute in the summer mink ration, C. F. BASSETT (*Amer. Fur Breeder*, 14 (1941), No. 6, pp. 38-40).—In four experiments, one-third to one-half of the 40 to 45 percent of raw meat in kit and adult mink rations was satisfactorily replaced by canned ocean whiting. Pelt quality, growth, and mortality were not significantly affected by the substitution.

[Abstracts of papers presented at the 33rd annual meeting of the Poultry Science Association—August 12-15, 1941, Stillwater, Oklahoma] [*Poultry Sci.*, 20 (1941), No. 5, pp. 454-478].—Papers relating to poultry production and management are as follows (see p. 461 for papers on poultry genetics): The Effect of Dietary Protein Supplements on the Toxicity of Selen-

iferous Grains for the Chick, by H. D. Anderson, W. E. Poley, and A. L. Moxon (p. 454) (S. Dak. Expt. Sta.); The Effect of Unabsorbed Yolks in Two-Week-Old Pullet Chicks on Subsequent Performance, by G. E. Bearse and C. F. McClary (p. 455) (West. Wash. Sta.); The Relation of Riboflavin to Growth and Paralysis in Chicks, by R. M. Bethke and P. R. Record (p. 456) (Ohio Sta.); Vitamin A Requirements of Growing Chicks—III, Effectiveness of Ester and Free Forms of Vitamin A in Dog Fish Liver Oil, by J. Biely, J. Pratt, and W. Chalmers (p. 456) (E. S. R., 76, p. 676); The Riboflavin Requirement of Turkeys for Hatchability, by R. V. Boucher, F. W. Hill, H. Patrick, and H. C. Knandel (pp. 456-457) (Pa. State Col.); Fat Absorption in the Laying Hen, by R. M. Conrad and H. M. Scott (p. 458) (Kans. State Col.); The Effect of Alfalfa Leaf Meal and Dried Cereal Grass on Hatchability and Egg Production, by W. W. Cravens and C. E. Holmes (p. 458) (Univ. Wis.); Cannibalism in White Leghorn Pullets in the Laying House, by J. A. Davidson, P. J. Schaible, A. W. Brant, and C. G. Card (p. 458) (Mich. State Col.); Studies on the Fat Requirements of the Domestic Fowl, by H. J. Davis and C. W. Upp (p. 459) (La. State Univ.); A Rapid Method of Scoring Body Conformation in Poultry, by R. L. Dolecek, W. O. Wilson, and W. E. Poley (p. 459) (S. Dak. State Col.); The 365-Day Egg Production Equivalent Table, by H. Embleton (p. 460) (Univ. Ariz.); Studies on Stability of Vitamin D, by J. C. Fritz, W. F. Archer, and D. K. Barker (p. 460); The Need for Pantothenic Acid and an Unidentified Factor in Reproduction in the Domestic Fowl, by M. B. Gillis, G. F. Heuser, and L. C. Norris (p. 460) (Cornell Univ.); Interference of Heated Diets on Calcification in Chickens, by J. C. Hammond, H. E. McClure, and D. Miller (p. 461) (U. S. D. A.); The Comparative Vitamin D Requirements of White Leghorn and Crossbred Chicks, and A Study of Methods for the Biological Assay of Vitamin D Supplements, both by V. Heiman and L. W. Tighe (pp. 461-462); Minerals in Rations of Battery Brooded Chicks, by V. G. Heller and R. Penquite (p. 462) (Okla. Sta.); Studies in Egg Quality—Interior Quality of Eggs as Indicated by Albumen and Yolk Indices, Yolk Color, Shell Thickness, Egg Shape, and Differences in Breeds and Strains for Same in Barred Plymouth Rocks, Rhode Island Reds, and White Leghorns, by W. Henderson, M. Narod, G. Cook, and E. A. Lloyd (pp. 462-463); The Feeding of Corn Cackle to Chickens, by G. F. Heuser and A. E. Schumacher (p. 463) (Cornell Univ.); Modifications in the Chick Vitamin D Assay Procedure, by S. R. Johnson (p. 464) (Ark. Sta.); Evidences of New Growth Factors for Chicks, by E. L. Johnson, C. W. Carrick, R. E. Roberts, and S. M. Hauge (p. 464) (Ind. Sta.); Growth of Turkey Poults on Simplified Diets, by T. H. Jukes (p. 464) (Univ. Calif.); The Effect of a Saline Extract of the Anterior Pituitary on Vitamin A and Fat Metabolism in the Fowl, by W. A. Maw and N. Nikolaiczuk (p. 466); Limited Range for Growing Turkeys, by T. T. Milby and R. B. Thompson (p. 467) (Okla. Sta.); "Gizzard Lesions in Day-Old Chicks," by D. Miller and H. W. Titus (p. 468) (U. S. D. A.); The Study of Calcium Metabolism in the Laying Hen by the Comparative Slaughter Method, by C. L. Morgan, J. H. Mitchell, R. C. Ringrose, and E. J. Lease (p. 468) (S. C. Sta.); Protein Utilization by the Growing Poult, by F. E. Mussehl, C. W. Ackerson, and R. H. Thayer (p. 469) (Univ. Nebr.); Further Evidence on the Cause and Occurrence of Blood and Meat Spots, by A. V. Nalbandov and L. E. Card (p. 469) (Univ. Ill.); Cane Molasses as a Constituent of Rations for Growing Fowls, by W. H. Ott, R. V. Boucher, and H. C. Knandel (p. 470) (Pa. State Col.); Influence of Height and Location of Feed and Water Containers on Egg Production of Single Comb White Leghorn Fowl, by R. Penquite and W. Land (pp. 470-471) (Okla. A. and M. Col.); Preliminary Observations on Choline in

(Chick Nutrition, by P. R. Record and R. M. Bethke (p. 471) (Ohio Sta.); The Response of Poults From Turkey Hens Fed Different Levels of Vitamin D, by E. I. Robertson, M. Rhian, and L. A. Wilhelm (p. 471) (Wash. Sta.); Studies on Detection of Fertility in Fresh Dissected Eggs by Radio Frequency, by A. L. Romanoff (pp. 471-472) (Cornell Univ.); Egg Quality Studies With the Storrs Contest Hens, by H. M. Scott (p. 472) (Univ. Conn.); Carotene Destroying Power of Certain Animal Feeds, by R. M. Sherwood and G. S. Fraps (p. 472) (Tex. Sta.); The Effect of Green Feed Supplement on Chick Growth, by R. M. Smith and S. R. Johnson (p. 473) (Ark. Sta.); Poisoning of Turkey Poults From Milkweed (*Asclepias galloides?*), by G. W. Stiles (pp. 473-474) (U. S. D. A.); Chloride Content of Blood of 11-Day Chick Embryos, by P. D. Sturkie (p. 474) (Cornell Univ.); The Effect of Heat on the Growth Promoting Value of a Specific Ration for Chicks, by R. H. Thayer and F. E. Mussehl (pp. 474-475) (Univ. Nebr.); Gizzard Erosion and Feathering in Chicks as Influenced by the Diet, by J. N. Thompson and H. L. Wilcke (p. 475) (Iowa State Col.); The Iodine Requirements of Growing Chickens, by H. S. Wilgus, Jr., G. S. Harshfield, A. R. Patton, L. P. Ferris, and F. X. Gassner (p. 477) (Colo. Sta.); and Physical Measurements of Fattening and Fleshing in Chickens, by W. O. Wilson, R. L. Dolecek, and A. L. Moxon (p. 477) (S. Dak. State Col.).

**Institutional poultry work in a poultry deficient State, C. W. UPP.** (La. State Univ.). (*U. S. Egg and Poultry Mag.*, 48 (1942), No. 1, pp. 25-26, 61-62).—A review of extension and research work on poultry is given.

**Studies of calcium and phosphorus metabolism in relation to the chemical structure of bone.—II, Experiments with moulting birds, C. TYLER** (*Biochem. Jour.*, 34 (1940), No. 10-11, pp. 1427-1430, fig. 1).—In continuation of this series (E. S. R., 83, p. 811) on the Ca and P exchanges in two molting hens receiving supplements of calcium gluconate or calcium carbonate, it is shown that the changes in the Ca of the  $\text{Ca}_3(\text{PO}_4)_2$  and residual Ca of bone were similar in molting to the changes taking place in the normal laying birds described in the previous study. One hen 81 days in molt showed the same reciprocal relationship between changes in  $\text{Ca}_3(\text{PO}_4)_2$  and residual Ca of the bone as in the laying hens.

**The study of the respiratory behavior of individual chicken embryos, A. L. ROMANOFF.** ([N. Y.] Cornell Expt. Sta. et al.). (*Jour. Cell. and Compar. Physiol.*, 18 (1941), No. 2, pp. 199-214, figs. 7).—The oxygen consumption of chicken embryos per unit of weight was found to decline with increasing age. Individual variations in respiration were associated with differences in morphological age at the first and second days of incubation, incidence of mortality on the fourth, thirteenth, and nineteenth days, and increased functional and physical activities with hatching on the twenty-first day. The respiration of some morbid embryos was below normal on the fourth and fifth days before death, and there was a reduction of as much as 60 percent on the day before death. A correlation of  $0.896 \pm 0.028$  was found between the body weight on the day of death and the amount of oxygen consumed on the day before death. It was evident that the oxygen consumption could be used in the detection of morbid embryos before their death.

**Observations on the mineral metabolism of pullets.—V, Acid-base equilibrium and reproductive activity, R. H. COMMON** (*Jour. Agr. Sci. [England]*, 31 (1941), No. 3, pp. 281-294, figs. 8).—Further study in continuation of the series (E. S. R., 83, p. 811) on the calcium balances and alkali reserves of seven pullets and one cockerel on cereal rations with and without supplements of calcium carbonate showed a prelaying increase in the alkali reserve of the blood

and the maintenance of a high level of the alkali reserve during laying when the high-calcium supplement was added to the ration. The alkali reserves of a cockerel did not show the fluctuations which preceded laying in the pullets. An increase of apparent digestibility of phytic acid phosphorus due to calcium metabolism of shell formation only became pronounced when birds on a high-calcium carbonate intake began laying intensely.

**Sunlamps for poultry**, D. C. KENNARD and V. D. CHAMBERLIN (*Ohio Sta. Bmo. Bul.* 213 (1941), pp. 177-182, fig 1).—Results based on growth, hatchability, and egg production equal to or slightly better than, those secured from feeding vitamin A and D oil were obtained by 1-7 hr. of daily exposure to the S-4 Type sun lamp (E. S. R., 84, p. 804). Although exposure for 1 hr. daily was sufficient for egg production and hatchability, more time was recommended pending final conclusions from further studies.

A review of egg legislation in the United States, R. L. BUTLER, L. A. WILHELM, and R. B. THOMPSON. (Okla. Expt. Sta.). (*U. S. Egg and Poultry Mag.*, 47 (1941), No. 12, pp. 730-733).—Suggestions are presented for inclusion in egg marketing legislation and regulations.

**Ducks and geese**, J. K. LIPSCOMB and H. HOWES ([*Gt. Brit.*] *Min. Agr. and Fisheries Bul.* 70 (1941), 3. ed., pp. [4]+37, pls. 6).—This revision (E. S. R., 71, p. 829) includes a section on ducks for egg production.

**Turkey work at Oklahoma A & M**, T. T. MILBY (*U. S. Egg and Poultry Mag.*, 48 (1942), No. 1, pp. 22-24, figs. 7).—Research in nutrition, management, breeding, and marketing of turkeys, including a description of the physical plant and teaching and service work, is briefly noted.

## DAIRY FARMING—DAIRYING

**Report of the Chief of the Bureau of Dairy Industry, 1941**, O. E. REED (*U. S. Dept. Agr., Bur. Dairy Indus. Rpt.*, 1941, pp. 51).—From dairy cattle investigations at the Beltsville, Md., Research Center and field experiment stations, results are briefly reported on progress in purebred dairy cattle improvement through breeding, colostrum injection as a skin test for pregnancy, various anatomical relationships in cattle and their relation to producing ability, the significance of mammary veining and the course of venous circulation of the udder, production costs and nutritive values of roughages including grazing crops, naturally cured and artificially dried hays and silages, the reaction of cattle to climatic conditions, and the value of applying liquid manure to pastures.

Reports from the division of nutrition and physiology include data on the determination of hydroxyamino acids in milk and the chemical reaction of amino acids; a study of unidentified nutritive factors in cow's milk; the vitamin A requirements of very young calves; the effect of cod-liver oil feeding on the fat content of milk; methods for determining carotene in hays, silages, and green forage; gonad-stimulating materials in plants; and various endocrine relationships in reproduction and lactation.

Reports of dairy products research dealt with the chemistry and bacteriology of milk, including the vitamin requirements of bacteria; the use of abrasives in the disintegration of bacterial cells; the composition of milk fat: causes of fat deterioration; structure of milk proteins; the heat stabilization of milk; factors affecting and methods for controlling the whipping properties of ice cream mixes; the utilization of dairy byproducts, including casein fiber, lactic acid lactones, and riboflavin recovery from whey; cheese investigations, particularly the pasteurization of milk for Cheddar cheese; milk quality and clarifica-

tion of milk as related to quality in Swiss cheese; the development of a cheese containing all the solids of milk; and the relation of quality to consumption of cheese.

From market milk investigations results are noted on the chloride and leucocyte content of milks produced by hand milking and by machine milking, the detection of added cow's milk in goat's milk, the effect of fat content and of homogenization temperature on the curd tension of milk, various factors affecting flavor in homogenized milk, and a summary of milk plant management surveys. The recently approved score cards for milk and cream and ice cream also are described.

**Dairy products for defense, A. J. MORRIS** (*Farm and Home Sci. [Utah Sta.]*, 2 (1941), No. 4, pp. 7-8).—Production goals for dairy products are outlined. The need for production of high-quality products suitable for defense needs is stressed.

**[Dairy investigations in Mississippi]** (*Miss. Farm Res. [Mississippi Sta.]*, 4 (1941), No. 11, p. 5).—Brief progress reports are presented for studies on the bitter principle imparted to milk when cows consumed bitterweed and the control of this weed in pastures, the efficiency of various rations in meeting the vitamin A requirements of dairy animals, vitamin E deficiency in cows, a comparison of two levels of calcium and phosphorus intake on the health and milk production of cows, and the mineral intake of cows under a free-choice system of mineral supplementation.

**[Dairy investigations by the New York State Station]** (*New York State Sta. Rpt. 1941*, pp. 16, 18-19, 24-25).—Brief reports of findings not previously noted include improved methods for paraffining milk bottle caps and paperboard containers, bacterial control in surface-ripened cheeses, gas production and oxygen consumption in ripened Cheddar cheese, the identification of white particles appearing on aged cheese, and the development of tests for determining the efficiency of homogenization and the fat content of homogenized milk.

**Higher milk production through improved management methods, G. Q. BATEMAN** (*Farm and Home Sci. [Utah Sta.]*, 2 (1941), No. 4, pp. 6-7, figs. 3).—This is a general discussion on the feeding of dairy cattle for maximum production. Improved pastures and increased feeding of concentrates are stressed. It is the author's opinion that Utah dairy production can be increased 13 percent or more by improved feeding and management practices and by milking more cows.

**Preservation of bovine spermatozoa in yolk-citrate diluent and field results from its use, G. W. SALISBURY, H. K. FULLER, and E. L. WILLETT.** (Cornell Univ. et al.). (*Jour. Dairy Sci.*, 24 (1941), No. 11, pp. 905-910).—A diluent composed of equal amounts of an M/15 solution of sodium citrate and fresh egg yolk was compared with the yolk-phosphate diluent of Phillips and Lardy (E. S. R., 83, p. 615) for the preservation of bovine spermatozoa. These preparations appeared to be of equal value in preserving the motility of spermatozoa stored at 5° C. for from 2 to 4 days. When held for 6 days or more, however, motility was better preserved in the yolk-citrate preparation. In actual insemination tests with semen stored up to 5 days, the results secured with semen stored in the yolk-citrate diluent did not differ significantly from those where the yolk-phosphate diluent was used (E. S. R., 84, p. 610.)

**The bacteriology of bull semen, I. C. GUNSALUS, G. W. SALISBURY, and E. L. WILLETT.** (Cornell Univ.). (*Jour. Dairy Sci.*, 24 (1941), No. 11, pp. 911-919).—The bacterial counts on 43 ejaculates obtained from 19 bulls by use of an artificial vagina ranged from 1,000 to 22,000,000 per cubic centimeter. Of the 12 bulls used in an artificial breeding association only 3 gave semen bacterial counts

of over 100,000 per cubic centimeter, and the average of the logarithms of these plate counts was 22,000 per cubic centimeter. In 28 samples collected from 7 bulls in the University herd (generally used for natural breeding), the average of the log of the plate counts was 225,000 per cubic centimeter, or approximately 10 times that of the association bulls. The predominating types of organisms in the various samples are indicated. Where bulls were subjected to muddy lots, douching the sheath and washing the underline markedly reduced the number of bacteria in the semen. When fresh eggs from healthy hens were used and aseptic methods employed in its preparation, an almost sterile yolk-phosphate diluent was consistently produced. Under other conditions the diluent was responsible for the addition of large numbers of bacteria to the semen samples. Little bacterial growth occurred in samples stored at 5° C. or lower.

**Estimation of initial live weight at each lactation of dairy cows,** W. L. GAINES, H. P. DAVIS, and R. F. MORGAN. (Ill. and Nebr. Expt. Stas.). (*Jour. Dairy Sci.*, 24 (1941), No. 11, pp. 983-992, figs. 3).—Based on an analysis of over 5,500 live weight and chest girth measurements for Ayrshire, Guernsey, Holstein, and Jersey cows, taken at the Nebraska Station over a period of 19 yr., an equation has been derived for estimating the live weight during the first month of lactation (initial live weight) from the chest girth. The equation is  $W=0.342 (G+g)^{1.35}$ , where  $W$  is initial live weight in pounds,  $G$  is actual chest girth in inches, and  $g$  is a girth modifier for age and breed of cow, being 0 for Jersey cows under 3 yr. of age and ranging up to 9 for Holstein cows 5 yr. of age or older. It is shown that in the application of a formula  $W=aG^b$ , the value of the exponent  $b$  varies widely with breed, age, and stage of lactation of the animal, ranging from a minus value to +2.93. By adopting the compromise value of 1.85 for  $b$ , as in the above formula, and applying a correction for breed and age, initial live weight estimates of reasonable accuracies may be obtained from chest girth measurements. A steel tape bearing on the face of the case a table of weights and modified girth is described.

**The effect of vitamin A and certain members of the B-complex upon calf scours,** P. H. PHILLIPS, N. S. LUNDQUIST, and P. D. BOYER. (Wis. Expt. Sta.). (*Jour. Dairy Sci.*, 24 (1941), No. 11, pp. 977-982).—The application of vitamin therapy in attempts to control calf scours in two dairy herds is reported.

In a Holstein herd experiencing marked troubles with calf scours, the administration of 10 cc. per week per calf of shark-liver oil (15,000 International Units of vitamin A per gram) gave temporary improvement in all cases, but only one-half of the calves recovered sufficiently to show no effect of the disease.

In a Jersey herd badly infected with this disorder, the administration of shark-liver oil as above, plus a mixture of vitamin B<sub>1</sub>, riboflavin, pantothenic acid, choline, and nicotinic acid at the respective rates of 1, 1, 5, 5, and 10 mg. daily, completely controlled the calf scours. Supplementary trials gave evidence that nicotinic and pantothenic acids probably were the factors of the vitamin B complex particularly needed under the existing feeding plan. Blood analyses indicated that newborn calves generally are well fortified with ascorbic acid but very deficient in vitamin A. The ingestion of normal colostrum quickly resulted in normal blood plasma carotene levels. The vitamin A in the blood of newborn calves appeared to be only slightly influenced by the vitamin A intake of the dam. Low ascorbic acid values in the blood plasma were increased by the feeding of shark-liver oil.

**Blindness in cattle due to papilledema,** J. O. WETZEL and L. A. MOORE (*Amer. Jour. Ophth.*, 23 (1940), No. 5, pp. 499-513, figs. 9).—This report, present-

ing detailed case histories of six calves which developed blindness due to the constriction of the optic nerve and associated with papilledema, supplements earlier reports on the effect of vitamin A deficiency in the rations of calves (E. S. R., 85, p. 241).

Some ocular changes and deficiency manifestations in mature cows, fed a ration deficient in vitamin A, L. A. MOORE (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 24 (1941), No. 10, pp. 893-902, pl. 1, figs. 2).—In further studies, six mature cows were maintained on a low-carotene basal diet for extended periods. When the plasma carotene values receded to a level of 0.2 to 0.5  $\mu$ g. per cubic centimeter, acute vitamin A deficiency symptoms soon followed in all cases. These included night blindness, incoordination, and an edema of the legs. None of the animals developed blindness due to a constriction of the optic nerve, such as commonly occurs in calves. A definite papilledema developed in four of the cases, and once this condition had begun a considerable time was required for it to recede after adequate feeding was resumed. An ocular change resulting from vitamin A deficiency, described in detail, was characterized by bleaching of the tapetum lucidum, followed by a mottled appearance of both the tapetum lucidum and the tapetum nigrum. It is noted that a Guernsey cow which succumbed to vitamin A deficiency had a very yellow fat at autopsy, evidently due to the presence of carotene, which suggests that animals are unable to draw extensively from this store of the pigment.

The production of high vitamin A milk by diet, H. J. DEUEL, JR., N. HALLIDAY, L. F. HALLMAN, C. JOHNSTON, and A. J. MILLER (*Jour. Nutr.*, 22 (1941), No. 3, pp. 303-313).—Tests were conducted with milking Guernsey cows to determine the effect of fortifying rations with shark-liver oil on the vitamin A content of the butterfat. During a preliminary period of 4 weeks, when all animals received the basal ration, the level of vitamin A excreted in the milk averaged around 40 International Units per gram of butterfat. Six animals, which were retained on the basal ration, continued to show similar vitamin A values, weekly averages ranging from 31 to 55 I. U. per gram of butterfat. When the remaining animals received a daily supplement of 30 cc. of shark-liver oil (700,000 I. U. of vitamin A), the vitamin A potency of the butterfat promptly rose to over 60 I. U. per gram. After 11 weeks, three of the animals received 60 cc. of shark-liver oil daily and the vitamin A values in the butterfat further increased to over 100 I. U. per gram, reaching a maximum in one case of 172 I. U. No toxic symptoms resulting from the feeding of shark-liver oil were noted, and cows receiving the supplement maintained a somewhat higher rate of milk and butterfat production than the untreated controls.

The effect of vitamin A intake on vitamin A content of butter fat, H. J. DEUEL, JR., N. HALLIDAY, L. HALLMAN, C. JOHNSTON, and A. J. MILLER (*Jour. Biol. Chem.*, 139 (1941), No. 1, pp. 479-480).—A résumé of research described above.

The effect of shark-liver oil on the vitamin A content of milk and on milk production, H. J. DEUEL, JR., and J. P. NUTTALL (*Certified Milk*, 16 (1941), No. 186, pp. 3, 19-22, figs. 3).—Based on research noted above.

The ascorbic acid content of cow's milk during pregnancy, A. D. HOLMES, F. TRIPP, E. A. WORLFFER, and G. H. SATTERFIELD. (Univ. N. C. et al.). (*Jour. Nutr.*, 22 (1941), No. 3, pp. 267-271).—Continuing investigations on the ascorbic acid content (E. S. R., 84, p. 236), milk obtained from Guernsey and Holstein cows at various stages of lactation and gestation was analyzed for ascorbic acid. Milk from Guernsey cows contained the highest average amount of ascorbic acid during the first month of pregnancy (average 22.47 mg. per liter), followed

by a gradual and fairly consistent decline with advance of pregnancy. Milk from Holstein cows showed a somewhat different pattern. Ascorbic acid values declined from the first to the fourth month of pregnancy, but increased consistently during the fifth, sixth, and seventh months and then declined during the late stages of pregnancy. A maximum average value of 17.87 mg. per liter was reached during the sixth month. While a gradual downward trend in ascorbic acid values of milk with advance of pregnancy is indicated, different cows showed considerable variation at all stages of gestation.

**Oxidized flavor in milk.**—IX, The effect of the quality of hay and early stage of lactation on the carotene content of butterfat and on the ascorbic acid content of the milk and their relationship to the development of metal-induced oxidized flavor, W. C. BROWN, A. H. VANLANDINGHAM, and C. E. WEAKLEY, JR. (W. Va. Expt. Sta.). (*Jour. Dairy Sci.*, 24 (1941), No. 11, pp. 925-935, figs. 8).—This series is continued (E. S. R., 55, p. 526). In an experiment with Jersey cows known to produce milk susceptible to copper-induced oxidized flavor development, all animals were subjected to a carotene depletion period of 4 weeks. During the ensuing 8-week period the feeding of brown alfalfa hay of low carotene content to one group resulted in a further decrease in the carotene content of the milk but did not increase the intensity of oxidized flavor. The feeding of high-quality, green alfalfa hay, together with alfalfa leaf meal, to the other group caused a significant increase in the carotene content of the milk and greatly retarded or eliminated the tendency for oxidized flavor to develop. These and supplementary data suggested, however, that the carotene of the milk may not be the substance responsible for this reduction in susceptibility to oxidized flavor, but that some other substance or substances associated with it in green hay or alfalfa leaf meal may be the important factor or factors.

A study of the relation of the stage of lactation to carotene and ascorbic acid contents of milk indicated that the carotene level was highest at the beginning of the milking period, followed by a gradual decline to a normal level in a few weeks, whereas the ascorbic acid level was usually low immediately after parturition, increasing gradually to a maximum level in 7 or 8 weeks. It is concluded that ascorbic acid in the milk plays a minor role in the susceptibility of the milk to metal-induced oxidized flavor.

**Experiments on the use of certain antioxidants for control of oxidized flavor in dairy products,** W. J. CORBETT and P. H. TRACY. (Univ. Ill.). (*Food Res.*, 6 (1941), No. 5, pp. 445-459).—A wide range of materials was tested with respect to their antioxidative properties when added to milk, ice cream, or butter. In tests with pasteurized, copper-contaminated whole milk, tyrosine or its ethyl or butyl esters proved to be effective antioxidants when added in concentrations of 0.02 to 0.04 percent, and rarely did any undesirable off-flavor result from their use. The normal amyl esters of both tyrosine and leucine were also effective antioxidants, but each imparted an objectionable off-flavor to the milk. The diethyl ester of glutamic acid exerted little antioxidative effect and imparted an objectionable flavor. Additions of ascorbic acid to milk gave variable results. In concentrations ranging from 10 to 100 mg. per liter, oxidized flavor was retarded but not inhibited in metal-free milk, while in copper-contaminated milk this off-flavor was retarded for a time but beyond a certain point its development was accelerated by the presence of ascorbic acid. In concentrations of 50 to 100 mg. per liter, oxidized flavor developed before all of the reduced ascorbic acid disappeared. The addition of a pancreatic extract at 1:25,000 effectively prevented oxidized flavor development. Concentrated water extracts of cereal grains were also strongly antioxidative, the most effective

product resulting from the drying of a mixture of water extract of cereal flour and concentrated skim milk on a roller drier. Substances which retarded oxidized flavor development generally had no effect on the oxidation of ascorbic acid. Paper milk bottles treated with oat flour were only slightly, if any, more effective than untreated paper bottles in retarding the development of oxidized flavor in milk. The addition of water extracts of cereal flours or a commercially prepared Avenized sugar had only a slight antioxygenic effect on ice cream. The dried cereal extract-concentrated skim milk mixture was more effective in this respect. The addition to churning cream of a concentrated water extract of the cereal flours or the addition of an Avenized salt to the butter tended to retard oxidized flavors in butter (E. S. R., 86, p. 240).

The effect of processing on the nitrogen distribution in milk, S. G. MENEFEE, O. R. OVERMAN, and P. H. TRACY. (Univ. Ill.). (*Jour. Dairy Sci.*, 24 (1941), No. 11, pp. 953-968).—A semimicro method for determining total N in whole milk, as previously described (E. S. R., 84, p. 582), was applied in analyzing various protein fractions in milks processed in a number of ways. Data are presented on the total N, noncasein N, nonprotein N, globulin N, casein N, albumin N, and proteose N for the various samples. Pasteurization of milk at 145° F. for 30 min. and homogenization at normal and abnormal pressures produced no significant changes in N distribution. In addition to the coagulation of albumin and globulin in the evaporation of milk, there was evidence to indicate that some hydrolysis of the proteins occurs as a result of this processing. Condensing skim milk produced only slight changes in N distribution. The addition of steapsin, trypsin, and Euzylac to milk at 145° for 30 min. produced a definite hydrolysis of the milk proteins.

The effect of pasteurization on some constituents and properties of goat's milk, H. S. HALLER, C. J. BABCOCK, and N. R. ELLIS (U. S. Dept. Agr., *Tech. Bul.* 800 (1941), pp. 14, figs. 2).—Mixed herd samples of goat's milk collected at intervals over two lactation periods were pasteurized in the laboratory at 142°, 145°, or 147° F. for 30 min. and at 160° for 15 sec. Either the holder method or the short-time, high-temperature method of pasteurization decreased the solubility of the calcium and phosphorus salts and denatured the soluble albumin and globulin only slightly, the change being less than the normal variation of these substances in the milk. Both methods improved the flavor of the milk slightly and greatly improved its keeping quality. The holder method decreased the curd tension and the reduced ascorbic acid content of the milk considerably, and the short-time, high-temperature method reduced the curd tension only slightly and did not affect the reduced ascorbic acid. The phosphatase was inactivated sufficiently for the milk to pass the phosphatase test for proper pasteurization when heated only 5 min. at 143°, so that this test (as now used for cow's milk) cannot be applied to detect improper pasteurization of goat's milk. The effect of pasteurization on the solubility of calcium and phosphorous, on the denaturation of proteins, and on the ascorbic acid content of goat's milk is comparable to the effect of pasteurization on the constituents in cow's milk as reported by other investigators.

*Pseudomonas putrefaciens* in dairy plant equipment, H. F. LONG and B. W. HAMMER. (Iowa Expt. Sta.). (*Jour. Dairy Sci.*, 24 (1941), No. 11, pp. 921-924).—Using a special medium as previously described (E. S. R., 85, p. 102), isolation tests were made on such materials as curd and wood from various points in dairy plant equipment by direct smears and after enrichment in litmus milk at 3° C. for varying periods. Five separate cases are described in which *P. putrefaciens* was found to be present in churns and in the insulation of a leaky vat. Other types of organisms were isolated from cracks and

joints in churns, suggesting that in defective and highly contaminated butter much of the contamination may originate in the churns.

**A discussion of the new agar employed in making standard plate counts,** M. A. FARRELL (Pa. State Col.). (*Pa. Assoc. Dairy Sanit. Ann. Rpt.*, 16 (1940), pp. 90-92).—Based on the general trend of results obtained by several investigators in comparing the bacterial counts in milk obtained by plating on the old and on the new standard medium, the author is of the opinion that there is no need to revise the present standards for bacterial content of various grades of market milk in view of the adoption of the new medium.

**A study in cheese ripening: The influence of autolyzed cells of *Streptococcus cremoris* and *Streptococcus lactis* on the development of *Lactobacillus casei*,** P. A. HANSEN (*Jour. Dairy Sci.*, 24 (1941), No. 11, pp. 969-976, figs. 3).—Three methods of preparing suspensions of killed cells were employed: (1) Autolysis of the bacteria by adding sodium chloride and toluene to a suspension of cells and holding at 49° C. for 5 weeks, (2) sonic vibration of a cell suspension for from 10 to 30 min., and (3) sterilization of a fresh suspension. The results of four separate experiments are described in which the effects of these various preparations on the growth and lactic acid production of different strains of bacteria were determined. The development of *L. casei* and *Betacoccus cremoris* (*S. citrovorus*) was stimulated by the extracts of *S. cremoris* or *S. lactis*, as evidenced by increase in the end point of fermentation and the final bacterial crop. *L. helveticus* was not significantly stimulated by the presence of these preparations, nor were *S. lactis* or *S. cremoris* significantly stimulated when grown in media enriched by their own cell content. Preparations of autolyzed cells or sonic vibrated cells were more potent than the non-treated control suspensions of killed cells. In all instances the active principle was filtrable through a Seitz filter EK. It is suggested that the stimulation of *L. casei* by *S. cremoris* and *S. lactis* may play an important role in the ripening of cheese, where these species are found at first, then die and disintegrate, and are followed by *L. casei*. The phenomenon may also be of importance in butter and cheese cultures. The possibilities of employing the sonic vibrator as a tool in the study of associated growth of micro-organisms are discussed.

**"Phage" in cheesemaking,** C. K. JOHNS (*Canad. Dairy and Ice Cream Jour.*, 20 (1941), No. 2, pp. 18-19, 25, figs. 3).—This article supplements an earlier report on this study (*E. S. R.*, 85, p. 396) and offers practical suggestions for meeting the problem under factory conditions.

**Corn sirup solids improve frozen dairy products,** L. R. GLAZIER and M. J. MACK. (Mass. Expt. Sta.). (*Food Indus.*, 13 (1941), No. 6, pp. 68-70, 114-115, figs. 2).—Consumer preference studies supplemented by certain physical tests were employed to determine the desirability of replacing a part of the sucrose in ice creams, ices, and sherbets by corn sweeteners. Four series of comparable ice creams containing (1) 15 percent sucrose, (2) 11 percent sucrose plus 4 percent dextrose, (3) 11 percent sucrose plus 4 percent enzyme-converted corn sirup, and (4) 11 percent sucrose plus 4 percent corn sirup solids, were preferred with almost equal frequency when judged by over 200 consumers. Ice creams containing only sucrose were adjudged sweetest by 27.7 percent of the judges as compared with 25.6, 21.7, and 25.0 percent for series 2, 3, and 4, respectively. Lot 4 containing corn sirup solids was most preferred on the basis of body and texture, followed in order by lots 2, 1, and 3. The corn sirup solids raised the freezing point of ice cream slightly, increased mix viscosity, decreased the rate of melting, and had little effect on the whipping ability of the product. Replacing 25 percent of the sucrose in ices and sherbets with

corn sirup solids improved the whippability of the mixes and gave smoother products which were highly preferred by consumers. Surface crustation was also reduced by this practice.

**The temperature method for control of whipping in ice cream, A. LEIGHTON.** (U. S. D. A.). (*Ice Cream Rev.*, 25 (1941), No. 3, pp. 34, 74, 76, fig. 1).—A more complete account (E. S. R., 85, p. 520) of a discussion pointing out the practical application of the established relationship between temperature and overrun in ice cream mixes frozen in the batch freezer (E. S. R., 77, p. 847).

**Selection and use of color in ice cream, C. A. IVERSON.** (Iowa State Col.). (*Ice Cream Rev.*, 24 (1941), No. 11, pp. 36, 38, 40, 44-45).—This general discussion points out the importance of purchasing ice cream color in a form best suited to the volume used, and emphasizes the importance of avoiding bacterial contamination in ice cream through the use of unsanitary coloring material.

**Sandiness in ice cream—its causes and control, H. H. SOMMER.** (Univ. Wis.). (*Ice Cream Rev.*, 24 (1941), No. 11, pp. 109-111).—In this general discussion of the problem the author points out the importance of maintaining a proper ratio of water to serum solids in the ice cream mix in order to prevent the development of sandiness in ice cream. The formula  $\frac{100-x}{6.9}$  = percent serum solids (upper limit), in which  $x$  equals all solids other than serum solids in the mix, is proposed as a convenient basis for determining a safe level of serum solids to be incorporated in the mix.

## VETERINARY MEDICINE

**Index-catalogue of medical and veterinary zoology.—Part 5, Authors: E to Flynney, A. HASSALL, M. A. DOSS, R. M. TAYLOR, G. B. CARSON, and D. B. SEGAL** (U. S. Dept. Agr., 1941, pp. [1]+1177-1458).—A continuation of this index catalog (E. S. R., 84, p. 523).

**An inexpensive bacteriological incubator, C. S. BRYAN and L. F. JENNINGS.** (Mich. Expt. Sta.). (*Vet. Med.*, 36 (1941), No. 11, pp. 567-568, figs. 3).—Plans are given for the construction of an efficient, inexpensive bacteriological incubator devised at the station. The thermostatic control permits the regulation of temperature within the incubator from any point slightly above room temperature to one more than 37° C. An inside temperature of 37°±2° can be maintained under room temperature conditions varying from 1° to 39°. This incubator is particularly well adapted to the incubation of milk samples for the microscopic test for streptococcic mastitis, but it can also be used for other purposes.

**Parasitos de los animales domesticos [Parasites of the domestic animals], DON CARLOS CHAVARRIA A.** ([Costa Rica] Dept. Nac. Agr., Bol. Téc. 39 (1941), pp. [1]+47, figs. 27).

**A descriptive study of a spore-forming bacillus isolated from actinobacillotic-like lesions, L. B. SCHWEIGFR, D. TRAINER, and D. F. EVELETH.** (Ark. Expt. Sta.). (*Jour. Bact.*, 42 (1941), No. 2, pp. 285-286).—A spore-forming bacillus was isolated from actinobacilloticlike lesions, five separate isolations having been made from cattle and two from sheep. All cultures were subjected to complete morphological, cultural, physiological, and pathogenicity comparisons. The pathogenicity studies were carried out on calves, rabbits, guinea pigs, rats, chickens, and pigeons. Similar clinical lesions were produced in calves, guinea pigs, and rats. From the characteristics exhibited in the study, the organism is classified as belonging to the *Bacillus subtilis* group of the family Bacillaceae.

**Laboratory infections due to *Brucella***, K. F. MEYER and B. EDDIE. (Univ. Calif.). (*Jour. Infect. Diseases*, 68 (1941), No. 1, pp. 24-32).

A cytophagic reaction employed in the diagnosis of *Brucella* infection, M. JERSILD (*Jour. Infect. Diseases*, 68 (1941), No. 1, pp. 16-19).—Description is given of a cytophagic test in brucellosis in which inactivated serum, bacterial suspension, and citrated blood without opsonins are used. This test shows that serum from cases of undulant fever contains immune opsonins at an early phase of the disease. "The reaction is more sensitive than agglutination and complement fixation. It has certain advantages over the cytophagic reaction of Huddleson [E. S. R., 70, p. 527], as the blood does not need to be examined soon after collection; besides it reveals an inhibition of the phagocytosis which occurs when there is an especially high opsonin content in the blood. After a skin test (with Huddleson's brucellergen) there occur immune opsonins, most markedly if there is already a small amount of antibody in the blood. If the skin test is positive there occurs an abundance of antibodies (agglutinins, complement-fixing bodies, and immune opsonins), an expression of the fact that a previously infected organism can quickly mobilize its antibodies."

The isolation of *Brucella* from milk, R. BRADLEY, M. WOLF, F. ACTON, and C. A. HUNTER (*Jour. Bact.*, 42 (1941), No. 2, p. 286).—In the course of routine examinations, whey agglutination tests for *Brucella* were run on 1,788 samples of milk. Of these 262 were positive, and by plate isolations *B. abortus* was isolated and identified from 20 of these. In one herd of 56 cows 21 of 224 quarter samples gave positive whey agglutinations, and of this number *B. abortus* was isolated from 11. These isolations represented 5 cows with positive whey agglutinations from 7 animals. About 9 percent of this herd were discharging *Brucella* organisms into the milk.

The rôle of one species of cockroach and several species of flies in the dissemination of *Brucella*, H. H. RUHLAND and I. F. HUDDLESON. (Mich. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 371-372).—It is concluded from the two experiments here reported that *B. abortus* does not remain alive in the intestinal tract of the American cockroach for more than 24 hr. Only a few colonies were obtained on the culture medium from those that were positive. No evidence was obtained that this insect is an important conveyor of *Brucella*. In cultures made of houseflies, blowflies, and stableflies the amount of growth obtained was heavier and freer from contamination 48 hr. after exposure than at earlier periods. In view of the fact that well-known species of flies can excrete the organism with intestinal droplets for 4 days and possibly longer periods, they must be considered as one of the possible means of transmitting brucellosis from animal to animal and from animal to man.

The relation of *Brucella abortus* infection to the vitamin A content of fetal livers, G. H. HART and H. R. GUILBERT. (Univ. Calif. coop. U. S. D. A.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 390-393, 394).—Hypotheses regarding possible interplay between the action of vitamin A deficiency and *Brucella* infection, presented by the authors, are: "(1) Involvement of the fetal membranes by *Brucella* organisms may restrict the transfer of vitamin A to the fetus and membranes and thereby decrease vitality or cause death. (2) Vitamin A deficiency with its coincidental alteration in placental cells, vulnerable to deficiency because they are developing rapidly, could hasten the invasion and effect of the *Brucella* infection, which exhibits tropism for these tissues. (3) The resistance to infection produced in cattle by *B. abortus* strain 19 vaccine is a relative immunity which can be overcome by sufficiently severe natural infection. It is possible that either a degree of vitamin A deficiency or exposure to natural *Brucella* infection, which could not cause abortion when acting alone, might

effect actual expulsion of the fetus in vaccinated animals when acting together." Critical experiments to prove or disprove these possibilities have not been carried out.

**Studies on the relationship of brucellosis to periodic ophthalmia, E. L. STUBBS and W. G. LOVE** (*Jour. Amer. Vet. Med. Assoc.*, 99 (1941), No. 777, pp. 476-480, 481).—Report is made of 40 cases of periodic ophthalmia examined that were given agglutination tests for brucellosis. Six cases gave a slight agglutination in low dilutions which would be classed as suspicious on the basis of the test as used in cattle. The others were entirely negative. The case reports are followed by a tabulated summary. These findings fail to indicate any relationship between brucellosis and periodic ophthalmia.

**Chronic, atrophic type of brucellosal arthritis, E. GOLDFAIN** (*Jour. Lab. and Clin. Med.*, 27 (1941), No. 2, pp. 168-172, figs. 3).

**Virus diseases, with special reference to encephalomyelitis, C. A. MITCHELL** (*Canad. Jour. Compar. Med. and Vet. Sci.*, 4 (1940), No. 10, pp. 273-277).

**Studies in equine encephalomyelitis: Susceptibility of some mammals and birds, C. A. MITCHELL and R. V. L. WALKER** (*Canad. Jour. Compar. Med. and Vet. Sci.*, 5 (1941), No. 11, pp. 314-319, figs. 2).—The results of inoculations for the artificial infection of a number of mammals and birds in order to determine their susceptibility to the equine encephalomyelitis virus are summarized in tables. Using the western type of the virus, the mammals found quite susceptible were the horse, guinea pig, mouse, white rat, hamster, and chipmunk. Cattle were only slightly susceptible. Swine, sheep, goats, foxes, cats, ferrets, and rabbits were refractory. Groundhogs were susceptible when young. All young birds inoculated with the virus were very susceptible; older birds were resistant. The border line between the two was well defined. For example, chickens were very susceptible until 2 weeks of age, when they quickly became resistant. The virus was found only in the brains of mammals but in both brains and blood of birds which died from the infection. However, in general, the mammals were inoculated intracranially, the birds subcutaneously. No animal or bird studied became host to the virus with the possible exception of the goose.

**Isolation of western equine encephalomyelitis virus from a naturally infected prairie chicken, H. R. COX, W. L. JELLISON, and L. E. HUGHES** (*Pub. Health Rpts. [U. S.]*, 56 (1941), No. 39, pp. 1905-1906).—Record is made of the isolation of the western equine encephalomyelitis virus from both the brain and the spleen of a prairie chicken (*Tympanuchus cupido americanus*), known also as the pinnated grouse or prairie hen, that was shot south of Rugby, N. Dak., in August 1941, while human epidemic cases were occurring in the vicinity.

**Studies on equine encephalomyelitis.—I, Antigenic properties of pigeon-brain-tissue vaccine, R. GRAHAM and N. D. LEVINE** (*Univ. Ill.*). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 430-435).—In the work reported, the details of which are given in six tables, equine encephalomyelitis pigeon brain virus of the western strain was passed through 10 consecutive pigeon transfers by intracranial inoculation of 0.1 cc. of a dilution of 1:1,000,000. A titration of the pigeon-brain-tissue virus intracranially revealed approximately 5 billion pigeon lethal doses and 100 million guinea pig lethal doses of virus per gram. Three separate lots of pigeon-brain-tissue virus inactivated by the addition of 0.5 percent formalin showed a measurable degree of immunizing power in guinea pigs and also in pigeons following subcutaneous administration.

**Equine encephalomyelitis, A. H. BRUECKNER** (*Ind. Acad. Sci. Proc.*, 49 (1939), pp. 54-61).

**The incidence of glomerulonephritis in domesticated animals, R. F. LANGHAM and E. T. HALLMAN.** (Mich. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 99 (1941), No. 777, pp. 471-475, figs. 12).—Report is made of a study of 236 cases of nephritis in domesticated animals, among which only 7 were classified as glomerulonephritis. While the pathology of these cases was not identical with that described for man, the extent and distribution of glomerular lesions appeared to justify this classification. The primary lesions involved the renal corpuscles and were characterized by thickening of the basement membranes, increased amounts of connective tissue, and hyalinization. The tubules showed secondary changes characterized by cloudy swelling, fatty degeneration, hydropic degeneration, atrophy, and gradual replacement as the result of the intensive productive tissue changes.

**Biological and immunological studies of *Listerella*, L. A. JULIANELLE** (*Jour. Bact.*, 42 (1941), No. 3, pp. 367-383).—The conjunctivitis and keratitis induced by *Listeria* is considered the most characteristic symptom produced by the organism and constitutes a unique reaction in infectivity. Serologically the genus appears to be composed of at least two specific types, and it is possible the types are associated with ultimate animal origin. Antiserums of high agglutinating titers offer little or no protection in infection in mice. *Listeria* does not stimulate "heterophile" antibody during active infection or prolonged immunization. A list is given of 18 references to the literature.

**The identification of *Erysipelothrix* and its relation to *Listerella*, L. A. JULIANELLE** (*Jour. Bact.*, 42 (1941), No. 3, pp. 385-394).—In a study made of 13 different strains of *Erysipelothrix* all were found to ferment glucose, lactose, and *D*-levulose without production of gas; about one-half the strains form acid in galactose. "A number of other 'sugars' tested are not altered by any of the strains. *Erysipelothrix* is virulent for mice and rabbits, inducing fatal infection. During experimental infection, leucocytosis and mononucleosis are irregular and therefore unreliable as measures of infection. With death, the animals may or may not show focal necrosis of the liver. When this form of hepatitis is present the foci are smaller and less frequent than in experimental listerellosis. None of the strains when inoculated conjunctivally by instillation or swabbing induce the corneal responses seen in similar infection by [*Listeria*]. Following such inoculation, however, *Erysipelothrix* irregularly penetrates the conjunctiva and establishes a fatal bacteremia. Measured by the agglutination reaction, *Erysipelothrix* appears to be a single group antigenically which differs from the two immunological types of [*Listeria*]."

**The role of phagocytosis in natural and acquired immunity in avian malaria, W. D. GINGRICH** (*Jour. Infect. Diseases*, 68 (1941), No. 1, pp. 37-45, figs. 6).

**Ornithodoros turicata and relapsing fever spirochetes in New Mexico, G. E. DAVIS** (*Pub. Health Rpts. [U. S.]*, 56 (1941), No. 47, pp. 2258-2261, fig. 1).—Forty-one lots with a total of 604 *O. turicata* ticks were collected during a rapid tick survey made in 10 counties in southern and southeastern New Mexico. Of 40 lots tested, 8, representing 4 counties, namely, Roosevelt, Chaves, Lea, and Hidalgo, were found to harbor relapsing fever spirochetes.

**The influence of host and intermediate reservoir host in determining the epidemiologic pattern of bovine pseudorabies and swine influenza, R. E. SHOPE** (In *Problems and Trends in Virus Research*. Philadelphia: Univ. Pa. Press., 1941, pp. 55-66, fig. 1).

**Nitrate poisoning of livestock, W. B. DAVIDSON, J. L. DOUGHTY, and J. L. BOLTON** (*Canad. Jour. Compar. Med. and Vet. Sci.*, 5 (1941), No. 11, pp. 303-313).

**Sulfo-Merthiolate as a germicide, H. M. POWELL and W. A. JAMIESON** (*Ind. Acad. Sci. Proc.*, 49 (1939), pp. 45-53).

**Arteriosclerosis in cattle associated with pulmonary ossification**, G. T. BLECH. (U. S. D. A.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 400-406, figs. 11).—This contribution deals with arteriosclerosis as it occurs in cattle, including a general picture of the gross lesions and histopathology as seen in cases observed over a period of years, and reports a case of unusual interest that was received at the laboratory. The observations made of cases of vascular lesions in cattle encountered in the Federal meat inspection service over a considerable period of years are said to indicate definitely that arteriosclerosis is not of common occurrence in the bovine species in the United States.

**The effect of parturition on the blood picture of cows in health and during infection with *Brucella abortus***, L. C. FERGUSON, M. R. IRWIN, and B. A. BEACH. (Univ. Wis. coop. U. S. D. A.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 394-399, figs. 2).—Records of the daily averages of the various cellular constituents of bovine blood during a 34-day period preceding and a 34-day period following parturition are presented in graphs. It appears that infection with *B. abortus* does not greatly influence the blood count during the parturient period, since the general trends, apparent in both "normal" and "infected" cattle, were similar. "The number of erythrocytes per cubic millimeter increased slightly immediately following calving and then decreased somewhat below the precalving level in the last 24 days of the postcalving period. The total number of leucocytes decreased significantly immediately following parturition and later increased to about the precalving level. There were no significant changes in the percentages of either the neutrophils or the lymphocytes in the period studied. The percentage of monocytes increased considerably in the 10-day period following calving but returned to the normal or precalving figure in the following period. The percentage of eosinophiles seemed to vary inversely with that of the monocytes, since in the 10-day period following parturition the proportion was significantly decreased, after which there was a return to about the precalving level. The fluctuations which normally occur in the number of leucocytes and in the proportions of the different types are greater in the parturient period than at other times. Therefore, results from a single blood count made on a cow during this period of physiologic disturbance should not be confused with a pathologic response."

**Studies on cowpox.—I, An outbreak of natural cowpox and its relation to vaccinia**, H. R. HESTER, L. E. BOLEY, and R. GRAHAM. (Univ. Ill.). (*Cornell Vet.*, 31 (1941), No. 4, pp. 360-378, figs. 7).—Report is made of an outbreak of natural cowpox or a disease clinically indistinguishable from it which occurred in a purebred herd of some 300 dairy animals.

**Experimental studies of ephemeral fever in Australian cattle**, I. M. and M. J. MACKERRAS and F. M. BURNET (*Austral. Council Sci. and Indus. Res. Bul.* 136 (1940), pp. 116, pls. 2, figs. 10).—The results of the survey reported are summarized in the general statement "that ephemeral fever is closely related to human dengue, that it is almost certainly insect-borne, that transmission is most probably cyclical, that the vector is probably a sandfly, and that the disease is likely to remain permanently as a recognizable clinical entity in Australia. It will be observed that we have made no mention of the way in which it may have entered Australia, but to the solution of that problem we have nothing to add."

**An irritant for udder tissues produced by mastitis streptococci in milk**, W. D. POUNDEN and C. E. ZEENER. (Univ. Wis. coop. U. S. D. A.). (*Cornell Vet.*, 31 (1941), No. 4, pp. 382-388).—In the work reported, injections of whey, resulting from the action of mastitis streptococci on milk, were made into milking and "dry" bovine udders. The results show that the products resulting from the in vitro action of mastitis streptococci on milk incubated at body temperature

produce a syndrome when injected into the mammary gland of the cow which is similar to if not identical with acute streptococcic mastitis.

**Deferred milking**—a method of handling acute streptococcic mastitis cases, W. D. POUNDEN. (Univ. Wis. coop. U. S. D. A.). (*Cornell Vet.*, 31 (1941), No. 4, pp. 339-344).—Report is made of the treatment of an attack of acute catarrhal and 16 acute parenchymatous streptococcic mastitis cases by deferring milking. In a case of acute parenchymatous streptococcic mastitis temporary relief was obtained when a cow was milked at least six times per day and sulfanilamide administered. Another severe attack in the same quarter and similar attacks in two quarters on another cow were successfully handled by discontinuing milking of the affected quarters until the acute inflammatory reaction subsided and they returned to their original soft pliable texture. Ten cases were treated for mild attacks in a similar manner. Two severe attacks that occurred when a milking was omitted for the purpose of drying off the animals were similarly handled. Satisfactory results were obtained and both udders functioned normally when the cows freshened again. The time required for resolution of the inflammation in these 14 cases never exceeded 3 days. Delay in starting treatment was the probable cause of failure in one instance and premature resumption of milking in another. A case of acute catarrhal mastitis involving two quarters was treated by this method unsuccessfully.

**Iodized mineral oil as a treatment for bovine mastitis**, D. A. SANDERS. (Fla. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 407-410, fig. 1).—Observations made on a limited number of animals indicate that iodized mineral oil has valuable therapeutic properties as a treatment for chronic bacterial infections of the bovine udder.

**The application of sodium azide to microscopic tests for bovine streptococcic mastitis**, C. S. BRYAN. (Mich. State Col.). (*Jour. Bact.*, 42 (1941), No. 2, p. 293).—The test considered consisted of a microscopic examination of properly collected milk samples incubated at 37° C. for at least 12 hr. The use of a selective preservative yielding a final dilution of 1:15,000 of sodium azide, 1:5,000 of bromocresol purple, and 1:1,000 of glucose in the milk increased the accuracy of the results of the test as compared to the use of no preservative or brilliant green 1:50,000, and greatly reduced the time required to read the results by suppressing both the udder micrococci and contaminating bacteria.

**Observations on the longevity of the liver fluke *Fasciola gigantica* in cattle**, J. E. ALICATA and L. E. SWANSON. (Hawaii Expt. Sta.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 477-478).—Experiments conducted have shown that in an infection with *F. gigantica* most of the flukes are eliminated by the end of 1 yr., but some of them may survive for at least 3 yr. and 4 mo. Details of an experimental infection of five steers with *F. gigantica* are presented in table form.

**Calf vaccination—United States experimental project (New York State)**, A. WINTER (*Cornell Vet.*, 31 (1941), No. 4, pp. 355-360).—A progress report of work in which 1,172 calves chosen from 25 herds were vaccinated and maintained in the parent herds without any segregation from the older infected unit at any time. Approximately 80 percent of the calves vaccinated are said to have given negative blood reactions within a 12-mo. period.

**Calfhood vaccination**, M. WELSH (*Md. Agr. Soc., Farm Bur., Rpt.*, 25 (1940), pp. 262-266).

**Suggestive evidence of trace element deficiency in Illinois sheep**, W. L. WRIGHT. (Univ. Ill.). (*Vet. Med.*, 36 (1941), No. 11, pp. 572-573, fig. 1).—A condition in lambs in an Illinois flock characterized by emaciation, anemia, and weakness, and in which improvement followed the feeding of a mineral mixture

containing iron, copper, magnesium, manganese, and cobalt, is described. A trace mineral deficiency in some Illinois soils is suggested.

**A phenothiazine experiment statistically treated, B. G. PETERS, J. W. G. LEIPER, and P. A. CLAPHAM** (*Jour. Helminthol.*, 19 (1941), No. 1-2, pp. 9-24).—Powdered phenothiazine administered to lambs as a drench in doses of 0.3 gm. per kilogram of body weight had no very marked effect on the worm burden as measured by egg counts and no effect in 3 weeks on worm counts and the weights of treated lambs.

**A controlled experiment with phenothiazine in sheep, J. W. G. LEIPER, B. G. PETERS, and P. A. CLAPHAM** (*Jour. Helminthol.*, 19 (1941), No. 1-2, pp. 25-34).—As judged by worm counts on 6 lambs, phenothiazine at the rate of 1 gm. per kilogram of body weight was without effect, whether given as compressed tablets or as a drench. As judged by egg counts per lamb on 12 lambs, before and after treatment, phenothiazine at the above rate significantly reduced the egg output of the worms. As judged by lamb weights, before and after treatment, powdered phenothiazine at the above rate was without effect during the brief course of the experiment. The tablets, on the other hand, led to a significant set-back in weight as compared with powder. In comparison with a drench made up with powder, the 5-gm. tablets were much easier to administer, but they had a significantly inferior effect on egg counts and lamb weights and at least in one case a tablet failed to disintegrate in 5 weeks.

**A note on the failure of phenothiazine as an anthelmintic against *Strongyloides papillosus* of sheep, G. P. KATZAL** (*Jour. Council Sci. and Indus. Res. [Austral.]*, 14 (1941), No. 3, pp. 218-219).—The administration of 0.6 gm. of phenothiazine per kilogram of body weight to 4- to 5-month-old lambs had no effect on *S. papillosus*, and egg production of the females was unaffected. It prevents further development of the eggs passed during the 2 days following treatment, but thereafter the normal rate of development of larvae gradually recurs.

**Treatment of ovine taeniasis with lead arsenate, E. C. McCULLOCH and J. E. MCCOY.** (Wash. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 99 (1941), No. 777, pp. 496-497).—Experiments with three yearling lambs affected with parasitism by tapeworms indicate that the administration of 0.5 gm. of lead arsenate per lamb is a reasonably safe and effective taeniafuge against *Moniezia* sp. Phenothiazine in doses of 24 gm. to seven such lambs had no effect on tapeworms of this genus.

**Blood-concentration studies on sulfanilylguanidine in swine and sheep, H. S. CAMERON and W. A. McOMIE.** (Univ. Calif.). (*Cornell Vet.*, 31 (1941), No. 4, pp. 321-330).—The findings in a study on the blood and fecal concentrations and the toxicity of sulfanilylguanidine administered orally in varying doses to swine and sheep are reported. Swine were found to have a greater tolerance for the drug than lambs. Repeated treatments of 1 gm. per 20 lb. of body weight given twice daily for 5 days do not injure swine but are toxic for lambs. Dosage of 10 gm. per 20 lb. twice daily for 5 days was toxic for swine. Massive single doses as high as 1 gm. per pound of body weight produced no symptoms of toxicity. The absorption rate is considerably lower than that of sulfanilamide, but a greater amount relatively is conjugated. Dosage and blood concentrations on eight clinical cases of swine enteritis are given.

**Lancefield group E streptococci in cervical abscesses of swine, H. J. STAFSETH and I. CLINTON.** (Mich. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 99 (1941), No. 777, pp. 468-470).—Lancefield group E streptococci, heretofore isolated only from certified milk, were isolated by the authors from cervical abscesses of a 7-month-old pig.

***Shigella equirulis* infection in a sow, P. R. EDWARDS and E. L. TAYLOR.** (Ky. Expt. Sta.). (*Cornell Vet.*, 31 (1941), No. 4, pp. 392-393).—Report is made of

the case of a *S. equirulis*-infected sow that succumbed to septicemia. It is pointed out that this sow came from a farm used primarily for the production of standard-bred horses.

**Connective tissue tumors of horses and mules**, R. A. RUNNELLS and E. A. BENBROOK. (Iowa State Col.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 427-429, 430, fig. 1).—A study made of 156 tumors that originated from various types of connective tissue in horses and mules in Iowa is reported. Benign neoplasms were encountered 65 times and malignant ones 91 times. In no particular age group was the incidence of benign connective tissue tumors significantly higher than in other age groups. More than one-half of the sarcomas occurred in horses between 1 and 4 yr. of age, inclusive. Fibromas constituted more than 50 percent of the benign tumors. Fibrosarcomas led the incidence rate among the malignant tumors with a percentage of 89. Fibromas often had their origin at sites of previous injury. The head and nasal passages were the seats of most common occurrence for more than one-half of the benign tumors. Among the sarcomas 39 percent were removed from the head and nasal passages, 30 percent from the limbs, and the remaining 31 percent from scattered regions of the surface of the body.

**Soil properties in relation to the occurrence of grass sickness in horses**, A. B. STEWART (*Jour. Agr. Sci. [England]*, 31 (1941), No. 3, pp. 308-319).

**The preservation of horsesickness vaccine with "Merthiolate,"** J. H. MASON and R. A. ALEXANDER (*Jour. So. African Vet. Med. Assoc.*, 12 (1941), No. 1, pp. 1-11).—Report is made of nine experiments which have shown that the use of Merthiolate (sodium ethyl mercuri thiosalicylate) as a preservative in concentrations of from 1:10,000 to 1:20,000 has no appreciable adverse effect on horsesickness virus during a period of 3 mo. at 5° C. and of 43 days at between 17° and 23°. In these concentrations it is a much better bactericidal and bacteriostatic agent than ether. A concentration of 1:20,000 would appear to be sufficient to destroy the chance contaminant that might gain access to horsesickness vaccine. In a strength of 1:20,000 it is an excellent preservative for neurotropic horsesickness vaccine and is said to be used as a routine.

**Experimental studies on the curative treatment of surra in native horses in the Philippines**, III, with a report on the results obtained in British North Borneo, L. M. YUTUC (*Philippine Jour. Sci.*, 75 (1941), No. 2, pp. 105-129).—In continuing these studies (*E. S. R.*, 77, p. 702), naganol-atoxyl therapy was found valueless in the treatment of equine surra. When naganol was combined with sodium antimony tartrate and administered in nonlethal but slightly toxic doses, 2 out of 5 artificially infected surra horses and 1 out of 3 naturally infected animals recovered from the disease. Furthermore, from the field trial carried out in British North Borneo during the summer of 1938, of the 100 horses naturally infected and actually given the naganol-sodium antimony tartrate combination, 63 were cured of surra.

**A resumé of studies and observations on infectious anemia, or swamp fever of horses**, carried on by the Bureau of Animal Industry from 1935 to 1940, C. D. STEIN, O. L. OSTEN, and L. O. MOTT (*U. S. Dept. Agr., Bur. Anim. Indus.*, 1941, pp. 9).—A summary is given of the work of the U. S. D. A. Bureau of Animal Industry with infectious anemia commenced in 1935, contributions relating to which have been noted (*E. S. R.*, 81, pp. 111, 717; 82, p. 391; 85, pp. 670, 825; 86, p. 94).

**Hemorrhagic anemia studies in dogs**, J. M. MCKIMBIN, A. E. SCHAEFER, and E. B. HART. (Univ. Wis.). (*Jour. Biol. Chem.*, 140 (1941), No. 1, pp. LXXXVII-LXXXVIII).—It was found that phlebotomized dogs when fed a whole milk ration usually show an immediate remission from their anemia when given adequate iron and copper, but when these minerals are supplemented with cobalt

at a level of 2 mg. per kilogram of body weight per day the dogs fail to respond. The resulting anemia is microcytic and resembles that arising from vitamin B<sub>12</sub> deficiency. When this ration is supplemented with 50 gm. of whole dry liver or 25 gm. of liver extract powder, the inhibition due to cobalt is overcome and remission from the anemia occurs. This is characterized by a striking increase in the red cell count, hemoglobin, hematocrit, and plasma iron levels of the blood. Saturation indices and mean corpuscular volume remain essentially the same as in the anemic condition. The ash fraction of liver extract was found to be inactive in overcoming the anemia as was a mixture of thiamin, riboflavin, nicotinic acid, pyridoxine, pantothenic acid, and choline at those levels in which these factors occur in the curative dose of liver extract. Ascorbic acid was also found inactive by both oral and intravenous routes. Some dogs receiving mineralized milk without cobalt fail to recover from their anemia after prolonged hemorrhage. The blood picture is very similar to that of the dogs receiving cobalt, and these dogs also respond to liver extract.

**Tularemia in dogs,** L. F. EY and R. E. DANIELS (*Jour. Amer. Med. Assoc.*, 117 (1941), No. 24, pp. 2071-2072).—In this report (E. S. R., 86, p. 252) evidence is presented to show that dogs may naturally acquire mild tularemia by the ingestion of infected rabbit material. Dogs so infected will develop *Pasteurella tularensis* agglutinins in high titer in less than 20 days. It is suggested that blood specimens from dogs manifesting potential *P. tularensis* infection be subjected to routine agglutination tests. Report is made of a case in which a man and his three dogs acquired the infection from the same rabbit, the man succumbing in 7 days while the dogs survived.

**Feeding rough fish to fur animals,** R. G. GREEN (*Conserv. Volunteer*, 3 (1941), No. 15, pp. 14-18).—A summary is given of the present knowledge of Chastek paralysis, a highly fatal disease due to a vitamin B<sub>12</sub> deficiency that occurs among foxes and minks on fur farms, particularly in Minnesota (E. S. R., 85, p. 672). This deficiency is caused through the destruction of vitamin B<sub>12</sub> by an unknown factor in ground raw carp when the whole fish forms 20 percent of the diet. Through controlled experimental work with 50 foxes it was determined that 1 lb. of such carp will destroy about 5,000 units of Vitamin B<sub>12</sub>, or more than a fox requires in an entire month. In feeding experiments it was determined that the edible filets, which consist of white muscle meat, do not contain the vitamin B<sub>12</sub>-destroying factor. The manner in which the fish is fed is important. If fish forms the basic ration it must be fed alternately with a ration that does not contain fresh fish. Cooking the fish every third day to destroy the vitamin B<sub>12</sub> inactivating factor will prevent the disease.

**Subacute arthritis and septicemia of streptococcal origin in silver foxes,** R. G. BENEDICT, W. WISNICKY and E. MCCOY. (*Univ. Wis.*). (*Jour. Amer. Vet. Med. Assoc.*, 99 (1941), No. 777, pp. 498-499, 500).—In a study of three cases of streptococcal arthritis and two of septicemia occurring in silver foxes, "animal pyogenes" (Lancefield group C) were found, through physiologic and serologic tests, to be the etiologic agent. Infective horse meat which formed a part of the ration was the most probable source of the organisms. Attempts to produce arthritis or septicemia in red fox pups by direct feeding of a pure culture isolated from one of the fatal cases of arthritis were unsuccessful.

**Some lungworm records from foxes in New York,** F. C. GOBLE and A. H. COOK (*Jour. Mammal.*, 22 (1941), No. 4, p. 456).—The finding of *Eucoleus aerophilus* in the trachea and larger bronchi of 22 red foxes and *Oncosoma vulpis* in the bronchi of 6 red foxes and 2 gray foxes that had been trapped in the

Helderberg Plateau region of southwestern Albany and northwestern Greene Counties, N. Y., is recorded.

**The toxicity of *Indigofera endecaphylla* Jacq. for rabbits,** M. W. EMMEL and G. F. RITCHIEY. (Fla. Expt. Sta. coop. U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 33 (1941), No. 7, pp. 675-677).—Several rabbits that grazed on plats of the leguminous forage plant *I. endecaphylla*, first introduced into Florida from Ceylon in 1925, succumbed to its intoxication in from 6 to 17 days. The symptoms and post-mortem findings are reported upon. No tests were made of its effect upon cattle, sheep, and mules, and no evidence was found that it is toxic to these animals.

**Poultry production may be increased through control of disease,** D. E. MADSEN (*Farm and Home Sci. [Utah Sta.]*, 2 (1941), No. 4, pp. 3, 10, figs. 4).—The part of disease control efforts in securing increased production of poultry products to meet the requirements of the National Agricultural Defense program is considered. The present practice of force feeding for year around production causes a drain on the reproductive system which may make the bird less resistant to infectious disease or cause a general organic break-down. Records kept by egg-laying contests operated in various States reveal an increase from the average mortality in 1913 of 6.3 percent to 30 percent in 1936. The application of control measures is dealt with as relate to stock resistant to pullorum disease, coccidiosis, infectious colds or "coryza," lymphomatosis, and the use of vaccine for fowl pox and laryngotracheitis.

**The vitamin A reserve of diseased fowls,** V. B. HOLLAND, G. H. SATTERFIELD, H. C. GAUGER, A. D. HOLMES, and F. TRIPP. (Univ. N. C. et al.). (*Poultry Sci.*, 20 (1941), No. 6, pp. 543-550).—In the study reported 85 fowls of various breeds, ages, and sexes which had been maintained under a wide variety of feeding and management conditions and were afflicted with various avian diseases and internal parasites were autopsied and the vitamin A and carotene content of their livers determined. These birds came from a wide variety of sources and had been maintained under extremely different management and feeding conditions. The affections represented included pullorum disease, fowl typhoid, coryza, botulism, coccidiosis, leucosis (neural), leucosis (visceral), fowl pox, epidemic tremor, avitaminosis A, tumors (unclassified), poisoning, internal parasites, crop-boundedness, salpingitis, and gizzard injury. The results have shown that the vitamin A reserve and carotene stored in the livers of birds afflicted with specific avian diseases vary over an extremely wide range. Therefore, with the exception of avitaminosis A, it is not possible to correlate a specific avian disease or internal parasite infestation with the vitamin A and carotene stores found in the liver of the domestic fowl.

**Avian thiamin deficiency: A correlation of the pathology and clinical behavior,** R. L. SWANK (*Jour. Expt. Med.*, 71 (1940), No. 5, pp. 683-702, pls. 4, fig. 1).

**Avian thiamine deficiency.—III, Characteristic symptoms and their pathogenesis,** R. L. SWANK and O. A. BESSEY (*Jour. Nutr.*, 22 (1941), No. 1, pp. 77-89, fig. 1).

***Aspergillus fumigatus* infection in adult chickens,** H. C. GAUGER. (N. C. Expt. Sta.). (*Poultry Sci.*, 20 (1941), No. 5, pp. 445-446).—Report is made of findings in a flock of 2,300 8-month-old Barred Plymouth Rock pullets that had access to spoiled mash and grain and showed symptoms of a respiratory affection. *A. fumigatus* was found to be the cause of respiratory and kidney lesions in these birds, the symptoms of which were not unlike those present in laryngotracheitis. Abnormal mortality did not occur, but egg production was temporarily lowered. Attempts at transmission gave negative results.

**Immunization against cecal coccidiosis in chickens by the use of X-ray-attenuated oöcysts, S. H. WAXLER.** (Univ. Wis.). (*Jour. Amer. Vet. Med. Assoc.*, 99 (1941), No. 777, pp. 481-485).—In the study of cecal coccidiosis reported there was found to be a progressive decrease in the hemoglobin content of the blood with an increase in the severity. As the amount of X-ray exposure was increased, there was a progressive attenuation of coccidial oöcysts. As the attenuation was increased, the severity of the disease from the treated cultures was decreased as indicated by the hemoglobin content. The attenuation of oöcysts by exposure to X-rays did not change within a period of 6 weeks. Chicks infected with a standardized X-ray-attenuated dose resisted a subsequent heavy reinfection almost as well as the survivors of a severe infection produced by untreated cultures.

**The chemotherapy of infectious coryza with sulfathiazole: Correlation between feeding levels and blood concentrations, F. S. SCHLENKER, J. P. DELAPLANE, and H. O. STUART.** (R. I. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 443-446, figs. 4).—The results obtained from the administration of sulfathiazole at the rate of 0.2 gm. per kilogram of body weight to eight cockerels have shown a rapid absorption of this drug to take place. "A peak concentration in blood is reached within 1½ to 3 hr. after oral administration when the birds are 'on feed'. An immediate drop takes place and then a slight rise, after which the residual amounts of the drug are eliminated. This regularity is forestalled when the drug is given in the absence of mash. No reason can be offered for these differences. The results indicate that from the standpoint of practicability it is necessary to keep sulfathiazole before the birds at all times in order to establish a constant effective level of the drug in the blood. A concentration of ¾ gm. of sulfathiazole per ounce of mash or greater (¼, ½, and 1 gm.) when fed ad libitum established a blood concentration which prevented the development of symptoms of coryza in artificially inoculated birds. When the drug level was lowered to ½ gm. per ounce, however, subclinical symptoms appeared. It is of interest to note that at a ¾-gm. level a maximum blood concentration of 2.4 mg. percent was established, whereas at the ½-gm. level this concentration was only 1.6 mg. percent. These results appear to be correlated with those obtained from cultural methods. It is possible that this lower level would prove effective in preventing the disease through contact exposure because of the great difference between the number of organisms used to inoculate the birds artificially and the relatively small number which would normally be present from natural exposure. From a practical standpoint the effective use of sulfathiazole would have to be based on knowledge concerning the status of the infection in each individual flock."

**Gizzard erosions, their prevalence and significance, A. E. TEEPER.** (Univ. N. H.). (*Mod. Agr. Soc., Farm Bur., Rpt.*, 25 (1940), pp. 315-319).

**The effects of variable dosages of sporulated *Eimeria acervulina* oöcysts on chickens, E. M. DICKINSON.** (Oreg. Expt. Sta.). (*Poultry Sci.*, 20 (1941), No. 5, pp. 413-424, figs. 4).—Report is made of studies of *E. acervulina* undertaken in an attempt to obtain information on (1) what effects variable dosages of sporulated oöcysts would have on body weight, egg production, feed consumption, symptoms, and mortality in susceptible chickens of different ages, (2) what dosages of sporulated oöcysts might be subclinical, clinical, or lethal, and (3) what effect continued feeding of sporulated oöcysts would produce in susceptible chickens. The effect of dosages of sporulated *E. acervulina* oöcysts that varied from approximately 5,000 to 25,000,000 of such oöcysts on egg production and body weight of Single Comb White Leghorn pullets of various ages is reported, the details being given in tables. The severity of the infection produced in

susceptible birds was in proportion to the number of sporulated oocysts administered in a single dosage. *E. acervulina* infection in susceptible pullets caused a loss in body weight and egg production, but was not considered a primary cause for mortality in these trials. Daily administration of 500,000 sporulated *E. acervulina* oocysts to susceptible pullets for 50 days did not produce a permanent or "chronic" detrimental effect. Protection or resistance against a heavy dosage of sporulated *E. acervulina* oocysts was consistently demonstrated in these trials. Although the resistance was sufficient to prevent gross clinical manifestations, it was not sufficiently solid to prevent a mild infection from occurring. The protection produced from a mild dosage of approximately 5,000 sporulated oocysts for 10 days appeared as solid as the protection from daily dosages many times that amount.

**The stage in the life cycle of *Eimeria tenella* influenced by sulphur,** O. E. GORF. (La. Expt. Sta.). (*Poultry Sci.*, 20 (1941), No. 5, p. 461).—In this series of experiments the first lot of chicks in each trial received sulfur 24 hr. before inoculation and continuously thereafter for the following 8 days. A second lot received sulfur 24 hr. before inoculation, but 24 hr. after inoculation the sulfur ration was replaced by the basal ration without sulfur. A third lot was inoculated and 24 hr. later given a ration containing sulfur which they received throughout the balance of the period. The sulfur was shown to have only a coccidiosis-preventive value. At 24-hr. intervals chicks from the various lots were selected at random and killed, ceca collected, and histological sections prepared and studied. Microphotographs were made of typical sections in each lot. A study of the material showed the stage in the life cycle of *E. tenella* affected by sulfur. The damage the parasite inflicted was also revealed.

**Carriers of *Hexamita meleagridis*,** W. R. HINSHAW and E. McNEIL. (Univ. Calif.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 453-458).—Studies of the incidence of *H. meleagridis* in adult turkeys that survived acute outbreaks and in other birds and animals killed on or near ranches where acute outbreaks had occurred and the results of some cross-infection experiments are reported. *H. meleagridis*, the cause of infectious catarrhal enteritis, was found in the intestine of 16.5 percent of live adult turkeys by rectal examination and in 32.4 percent at autopsy. In sexually immature birds the bursa of Fabricius was found to be a convenient source of material. The incidence of infection of *H. meleagridis* in adult turkeys is high enough to prove that the breeding stock is the most important source of infection. The domestic birds examined and found negative for *H. meleagridis* were chickens, pigeons, ducks, guinea hens, and peafowls. *H. columbae* was found in 8 (25 percent) of 32 pigeons examined. This species was not transmissible to poults. The game birds examined included quail, chukars, pheasants, sage hens, jungle fowls, and grouse. A species of *Hexamita* transmissible to poults was found in quail and chukars; the others were negative. Wild birds examined and found negative for *Hexamita* were blackbirds, English sparrows, linnets, butcher birds, towhees, hawk (1), owl (1), kingbird (1), and crow (1). Two toads and one alligator lizard were negative for *Hexamita*.

It was not possible to incriminate the fly as a carrier. The acute type of infectious catarrhal enteritis was produced in poults by oral and rectal injections of saline suspensions of *H. meleagridis* obtained from an adult carrier. This was accomplished by serial transfers in poults until heavy losses occurred in the group receiving the third serial injection. Cross-infection studies indicate that quail, chukars, and possibly ducks may act as carriers of *H. meleagridis*.

In an addendum it is stated that *H. meleagridis* persisted in the bursa of Fabricius and cecal tonsils for at least 22 weeks when the initial inoculation was made in chicks under 1 week of age. No symptoms of disease were ever produced. Because of these findings chickens also must be considered potential carriers, even though the parasite has not been found in farm flocks under natural conditions.

**Experimental infection of chicks with *Hexamita meleagridis***, E. McNEIL and W. R. HINSHAW. (Univ. Calif.). (*Cornell Vet.*, 31 (1941), No. 4, pp. 345-350).—In inoculation experiments *H. meleagridis* was shown to persist in the bursa of Fabricius and cecal tonsils of chicks for at least 22 weeks when the initial inoculation was made in chicks under 1 week of age. Rectal inoculation proved the most efficient method for establishing the infection. It was impossible to produce symptoms of infectious catarrhal enteritis in chicks by serial passages in chicks. The degree of infection in chicks was very light when compared with the number of organisms found in poults. Normal chicks placed in a brooder with infected poults acquired the infection. Normal poults placed in a brooder with infected chicks likewise acquired the infection. The chicken must be considered a potential carrier of *H. meleagridis*.

**A transmissible lymphoid tumor of the chicken**, C. OLSON, JR. (Mass. Expt. Sta.). (*Cancer Res.*, 1 (1941), No. 5, pp. 384-392, figs. 7).—An account is given of a transmissible lymphoid tumor of the chicken, with the results of the first 30 serial passages. Transmission was accomplished by transplants of tumor tissue. These transplants failed to grow in some chickens, in others regression took place after a short period of growth, and in still others growth was progressive and in some instances metastasized to the visceral organs. The results gave no indication of an etiological connection between the lymphoid tumor, fowl paralysis, or fowl leucosis. The transmissible neoplasm is unlike any other transmissible tumor described in the chicken. A list of 26 references to the literature is included.

**The effect of certain organic compounds and other dietary supplements on perosis**, T. H. JUKES. (Univ. Calif.). (*Jour. Nutr.*, 22 (1941), No. 3, pp. 315-326, figs. 2).—Further experiments dealing with the relation of choline and other dietary supplements to perosis are reported (E. S. R., 85, pp. 97, 673). Twenty-four references to the literature cited are given.

**Some problems concerned with the pullorum disease control program**, H. R. BAKER (*Id. Agr. Soc., Farm Bur., Rpt.*, 25 (1940), pp. 287-288).

**Mapharsen therapy in enterohepatitis of turkeys**, E. C. McCULLOCH and L. G. NICHOLSON. (Wash. Expt. Sta.). (*Vet. Med.*, 36 (1941), No. 11, pp. 574-576).—Experimental work indicated that the application of mapharsen (meta-amino-para-hydroxy-phenylarsine-oxide hydrochloride) therapy in the treatment of enterohepatitis of turkeys was safe and economical, and that it will save at least half of the birds provided adequate treatment is given within a reasonable time after clinical symptoms appear. Since it is known that approximately half of the liver function is impaired in enterohepatitis before clinical symptoms can be detected, and since the administration of therapeutic doses of this drug has no deleterious effect upon subsequent growth, it is suggested that all exposed birds be treated with light doses of mapharsen as soon as a diagnosis of blackhead has been established in the flock. It is possible that the dose of mapharsen can be reduced below 0.004 to 0.006 gm. per bird, especially in those cases where clinical blackhead has not appeared in the majority of the birds in a flock and repeated prophylactic doses may be indicated. These dosages would be proportional to the recommended dosages for humans if given to birds weighing between 10 and 15 lb.

**Trematode parasites of Philippine vertebrates.—IX, Flukes from the domestic fowl and other birds, M. A. TUBANGUI and V. A. MASILUNGAN** (*Philippine Jour. Sci.*, 75 (1941), No. 2, pp. 131–141, pls. 3).—Of the nine fluke forms noted, *Prosthogonimus pseudopellucidus*, *Episthmium gallinum*, and *Brachylacmus malayensis*, all from the domestic fowl, together with *Mesostephanus fregatus* from the small intestine of *Fregata ariel ariel* and *M. halliasturus* from the small intestine of *Haliastur intermedius*, are described as new. Twenty-three references to the literature cited are included.

## AGRICULTURAL ENGINEERING

**Hydrologic studies of the Putah Creek area in the Sacramento Valley, California, M. R. HUBERTY and C. N. JOHNSTON** (*Hilgardia [California Sta.]*, 14 (1941), No. 3, pp. 119–146, figs. 15).—The college of agriculture at Davis is located within the Putah Creek Basin, and in years of low rainfall, the underground basin is its sole source of water supply. The division of irrigation has observed underground-water conditions on the university farm for a long time.

Although shallow wells are affected by deep wells, their water-level fluctuations are in general out of phase with the deeper well levels, and they normally have water elevations higher than those of the deep wells nearby. In such areas as reclamation district 999, where shallow-water strata are under pressure, the surface layers may receive some water from the pressure-bearing strata below. Most of the ground-water supply of Putah Creek lower basin enters through the porous gravel beds near the head of the fan, in the vicinity of Winters. This area is potentially a great spreading basin. Although underground-water levels in the area north of Winters have been raised since 1912 by the use of the Capay Canal water, other parts of the area have had drops in water levels of from 15 to 25 ft. during the period. This lowering does not represent an overdraft, but rather the changes in head resulting from increased pumping. In dry periods, the recession is greater than usual. The recharge is good during years of normal or above-normal rainfall.

The boron content of the well waters varies widely. Cache Creek water imported into the district has had a marked influence upon some well waters. The data secured indicate a possible method of studying underground-water movements. The underground-water temperatures are uniform throughout the basin for all but the deepest wells, which tend to be several degrees warmer than the others.

**Chemical composition of water in the Putah Creek Basin, C. S. BISSEK and M. R. HUBERTY** (*Hilgardia [California Sta.]*, 14 (1941), No. 3, pp. 147–160, figs. 2).—Within the period of time covered, water from wells perforated at one stratum only but of various depths was remarkably constant with respect to chemical composition. Wells perforated at more than one stratum showed a variable salt content. In general, ground waters of Putah Creek Basin were found of good quality for irrigation. The total salt content is relatively low as is the sodium percentage. Some well waters, however, contain sufficient boron to cause injury to many crop plants. The well waters of this area are characterized by a relatively high bicarbonate content. The sodium percentage was found to increase with depth of water-bearing formation. The boron content varied between 0 and 2.02 p. p. m.

**The work of the United States Cotton Ginning Laboratory (U. S. Dept. Agr., Misc. Pub. 445 (1941), pp. [28], figs. 28).**—This is a mainly popular account of the purpose, equipment, and accomplished work of the ginning laboratory at Stoneville, Miss. The study of the cotton before ginning has shown that

trash brought in by careless picking may cause losses of as much as \$5 per bale and that the most complete cleaning equipment does not entirely offset the results of careless picking. Development of mechanical driers which increase the value of the ginned lint by from 70 ct. to \$2.50, according to staple length, at a fuel cost often less than 15 ct. per bale, is mentioned, together with increases up to nearly 20 percent in gin capacity brought about by raising saw speeds from 400 to 600 r. p. m. at a cost negligible in comparison with the gain in value of the cotton gin which may be obtained from this change and from the concomitant use of looser seed rolls. Study of the effects of variations in gin-saw design and the importance to proper doffing of keeping the brush drums and brushes in good repair are also taken up, as are packaging improvements, pure-seed handling equipment, reduction in power wastes, etc.

**Milk cooling on Kansas farms**, J. ROBERTS and G. H. LARSON (*Kansas Sta. Bul.* 295 (1941), pp. 39, figs. 18).—This investigation has already been noted from another source (E. S. R., 86, p. 398).

### AGRICULTURAL ECONOMICS

[Investigations of agricultural economics by the Ohio Station] (*Ohio Sta. Bimo. Bul.* 213 (1941), pp. 183–185).—An article on Tractors on Small Farms in Ohio, by F. L. Morison, is based on a study of farms ranging from 50 to 110 acres in a county in the western part of the State and a county in the north-eastern part. It includes tables showing for the farms grouped by type of power—horse only, horse and standard tractor, horse and general-purpose tractor, and tractor only (only the western county)—the average size of farm, number of men, crop acres, animal units, work units per man, and costs, total and per man work units, of labor, power, and machinery. The advantages and disadvantages of the different types of power for small farms are commented on briefly.

The usual table of index numbers (E. S. R., 86, p. 262) by J. I. Falconer is brought down through August 1941.

**Types of farming in California analyzed by enterprises**, L. A. CRAWFORD and E. B. HUBB. (Coop. U. S. D. A.). (*California Sta. Bul.* 654 (1941), pp. 128, pl. 1, figs. 31).—"The purpose of this bulletin is to present descriptive material of the natural and economic factors underlying and contributing to the development of this agricultural pattern so as to provide those interested in California agriculture with a general knowledge of the character of agricultural production in different parts of the State.

"There is presented first a brief review of the manner in which the underlying natural and economic factors operate in controlling agricultural production. This is followed by an illustrated description of the physiography of California to provide a basis of orientation and understanding of the crop and livestock localization in different parts of the State. The geographic distribution of the various crop and livestock enterprises is depicted graphically by means of dot maps of crop acreages and livestock numbers, followed by an explanatory discussion of the factors contributing to the enterprise localizations. Lastly, there is a graphic and descriptive presentation of the localization of various farm types as classified by the United States Bureau of the Census as a result of a special study of the 1930 Census of Agriculture."

**Supplementary tables for Bulletin [377], types of farming in Montana, study of area IV: Its past, present, and future.** (Coop. U. S. D. A.). (*Montana Sta. Mimeog. Cir.* [13] (1938), [pp. 43], fig. 1).—This circular supplements Bulletin 377 previously noted (E. S. R., 88, p. 258).

**A study of dairy-farm management in Onondaga County, 1938 and 1939.** R. W. HOEKER ([*New York*] *Cornell Sta. Bul.* 767 (1941), pp. 21).—Records of farm business were obtained and analyzed for 100 farms in the county for the crop year 1938, and 70 of the same farms for the crop year 1939. Tables are included and discussed showing data as to operator's ages, school attendance, tenure status, farming experience, etc.; kinds and costs of man labor; capital investment; farm receipts, expenses, and labor income; operator's privileges and earnings; etc. Analysis is made of the effects of size of business as measured by number of cows, by acres in cabbage, and by productive-man-work units, of diversity of farming, of labor efficiency, and of capital efficiency on labor income.

The average labor income for the 100 farms for the year ended March 31, 1939, was \$133, and on the 70 farms for the year ended March 31, 1940, \$498. The value of operator's privileges was approximately \$460 for each year. The increases in labor income in the 2 yr., respectively, due to increases in different factors were: One productive-man-work unit, 90 ct. and \$1.29; one cow, \$32 and \$44; one point in the crop index, \$13 and \$10; 1 cwt. of milk per cow, \$18 and \$14; one productive-man-work unit per man, \$8 and \$6; and 1-yr. decrease in the time required for the receipts to equal the capital, \$448 and \$422. "The most important factors affecting labor income both years were the total work units, crop index, milk per cow, and work units per man. Farms with none of these four factors as good as or better than average had a labor income of —\$344, while farms with all four factors as good as or better than average made a labor income of \$1,006, or a difference of \$1,440 per farm."

**Planning the farm business in the Bluestem Belt of Kansas.** R. J. DOLL (*Kansas Sta. Bul.* 294 (1941), pp. 23, fig. 1).—The area, the factors to be considered in farm business planning, and the preparation of farm budgets are briefly discussed. Budgets are prepared for five methods of using the farm resources of a 595-acre farm, with 140 acres of cultivated valley land, 5 acres of temporary pasture, 440 acres of upland pasture, and 10 acres of farmstead and waste land, and for five methods for a 320-acre upland farm, with approximately one-third of the land in cultivated crops. Tables list the standards—long-time average crop yields, man and horse work hours, seed, twine, fuel, and oil required for crop production, prices of different crops, and production and feed requirements for livestock—used in preparing the budgets. Other tables show comparisons of the acreages of different crops, numbers of different kinds of livestock, the production and gross receipts for each crop or kind of livestock, and the variable expenses under each method of organization for the two kinds of farms.

**Factors affecting financial success of farms outlined.** G. T. BLANCH (*Farm and Home Sci. [Utah Sta.]*, 2 (1941), No. 4, pp. 2, 11).—This article is based on 442 farm business records of cash-crop dairy farms in the vicinity of Ogden, Utah, during 1937–39. The relation of different factors to labor earnings is discussed.

The average labor earnings of the 442 farms were \$881. Those of 29 percent of the farms were less than \$500 and those for 13 percent over \$1,500. The data indicated that to obtain the average labor earnings, it was necessary to be better than the average in more than three of the following factors: Number of man-work units, crop index, pounds of butterfat per cow, man-work units per man, percentage of man-work units in crops, price received per pound of butterfat, and man-work units for each \$1,000 of capital.

**Some economic and social implications of the soil and water conservation program in the Little Mill Creek Watershed, Coshocton County, Ohio.** R. H. BLOSSER. (Coop. U. S. D. A.). (*Ohio State Univ., Dept. Rural Econ. Miscog. Bul.* 128 (1940), pp. [2]+36, fig. 1).—The locations, soil types,

land use, crop yields, livestock production, land tenure, labor income, etc., of the area are described. Surveys of the economic and soil conditions on 42 farms were made in 1935, 1936, and 1937. Records were kept by a group of the farmers who signed the cooperative agreements in 1938 with the U. S. D. A. Soil Conservation Service under its program which included adjustment of land use, application of lime and fertilizers, adoption of strip cropping, contours and cultivation on sloping lands, improvement of hay and permanent pasture lands, reforestation of steep and severely eroded lands, and elimination of oats and soybeans from rotations. The changes that have resulted and probably will result from 1935-37 due to the conservation plan with estimates of probable land use, value of crops, etc., are shown for an 80- and a 115-acre farm. How the conservation practices may affect the farm family and the difficulties of adopting the practices are also discussed.

The estimates indicated that the feed units of grain will be slightly reduced unless per acre yields are increased, that feed units of hay and pasture will be approximately doubled, that more labor will probably be needed to harvest the additional hay, and that on many of the farms 4 or 5 yr. will be required before the costs of adopting the recommended soil and water conservation practices will be completely recovered.

**Economic geography of South America**, R. H. WHITEBECK and F. E. WILLIAMS, assisted by W. F. CHRISTIANS (*New York and London: McGraw-Hill Book Co., 1940, 3. ed., pp. XI+469, figs. [204]*).—Single chapters are devoted to the continent as a whole, and Colombia, Venezuela and the Guiana Colonies, Ecuador, Peru, Bolivia, Uruguay, Paraguay, and South America as a Whole and Some of Its External Relationships. Chile is dealt with in two chapters: The Country as a Whole and Its Northern Mineral Region, and The Central Valley and the South. Argentina is considered in three chapters: Argentina, The Pampa, and Satellites of the Pampa. Brazil is dealt with in four chapters: General Description, Interior Tablelands, and Southern States, The Heart of Brazil, The Tropical Northeast and the Amazon Valley, and Transportation, Manufacturing, and Commerce.

**Agriculture in Uganda**, edited by J. D. TOTHILL (*London: Oxford Univ. Press, 1940, pp. XVI+551, pls. [33], figs. [10]*).—This volume, prepared by the staff of the department of agriculture of Uganda, describes the topography, vegetation, climate, native agriculture, soils, erosion problems, manure, experimental work, native food crops, plantation crops, tobacco, oil-yielding plants, spices and drug crops, fibers, cover crops and shade trees, fruits and vegetables, grazing crops, bees and locusts, marketing, and agricultural education and extension work. Special consideration is given to cotton, coffee, and sugar.

**Wheat in national diets**, M. K. BENNETT (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 18 (1941), No. 2, pp. [2]+37-76, figs. 6*).—Wheat is one of the more important foodstuffs in a group designated herein as cereal-potato foods. This study presents analyses of the quantitative position of this group in the average diets of 52 nations (1933-38), the quantitative position of wheat calories among total food calories and among the cereal-potato calories of these nations, and changes in the position of wheat between 1923-28 and 1933-38. Calories from cereals and potatoes constitute as little as 30 percent of total food calories in some countries, as much as 90 percent in others. Wheat contributes less than 5 percent of total food calories in several countries, mostly Oriental or tropical; and as much as 40-50 percent in others.

**Supply responses in milk production in southeastern Minnesota**, E. G. STRAND and E. HOLE (*Coop. Minn. Expt. Sta.). (U. S. Dept. Agr., Tech. Bul. 789 (1941), pp. 62, figs. 13)*.—This study is one of the series (E. S. R., 85, p. 684),

(the object of which is to compare the interregional competition between several dairy areas. The area dealt with in the present study embraces five counties—Dodge, Freeborn, Rice, Steele, and Waseca—in the southeastern part of Minnesota. The area is one of the most highly developed agricultural regions of the State and is in a transition area between the Corn Belt and the northern dairy region, and dairying is combined with the production of hogs, poultry, and cash grain. The agriculture of the area, the recent trend in production, and production trends and price relationships are described. Analysis is made of the production trends as shown by 24 accounting farms that had participated in the Southeastern Minnesota Farm Management Service during the period 1928-39 and by 150 farms in a survey sample in 9 adjoining townships in Freeborn, Waseca, and Steele Counties. Basic data for budget estimates of future production on individual farms in the area were drawn from these two selected sample groups. "The procedure has been to analyze the past trends in production for the area as a whole and then, by budgeting two representative groups of individual farms, to arrive at an estimate of the future production for the area in three possible future price situations: (A) A continuation of 1935 normal prices; (B) a 20 percent increase in butterfat prices; and (C) a 20 percent decrease in butterfat prices."

Butterfat production in the area apparently increased about 12 percent from 1927 to 1938. It is estimated that the milk production (for sale) in 1946 will be 9 percent greater than in 1936 if the 1935 normal price continues, 18 percent higher if there is a 20 percent increase in butterfat prices, and a decrease of 2 percent if butterfat prices are 20 percent lower. In summing up the authors state:

"Assuming continuation of the normalized prices prevailing in this area in 1935 (the A price situation), the normal production of butterfat in the area in 1945 will be increased by 9 percent over that in 1935. This increase will result not only from a small increase in cropland, but, more importantly, from the future expansion of alfalfa, the expansion of other high-yielding roughage crops, and the increased use of hybrid corn. The budgeting analyses revealed that hogs and poultry compete strongly with dairying in this area. Consequently, the added feed supplies, becoming available from hybrid corn and better feed-producing small grains, may tend to expand hogs and poultry more than dairying. Yet on farms where the possibilities of expansion in alfalfa or other roughage crops are as yet largely unrealized, dairying may increase just as much as hogs and poultry, and perhaps more.

"With an increase in the relative price of butterfat (the B price situation), some transfer of resources away from hogs, and to some extent from poultry, to dairy cows may be expected. The budgeting reveals, however, that even in this price situation dairying is not sufficiently superior on many farms to warrant more than a moderate increase in dairying at the expense of other enterprises. With a relative decline in prices of butterfat (the C price situation) production of butterfat is expected to be slightly less than the normal output in 1935. Budgeting of various farm organizations indicates that in this price situation alternative enterprises such as hogs, poultry, and beef cattle tend to become more profitable than dairying, and some contraction would be likely in the dairy enterprise. This contraction would be relatively larger than the estimated expansion in the event of an increase in prices of butterfat. The analysis of the interrelations of farm enterprises in this area and of the manner in which these enterprises would be affected by changes in price relationships should be of considerable value to individual farmers as well as to public agencies engaged in planning agricultural adjustments. Comparisons with areas in New England and in Wisconsin indicate that responses in dairy production are influenced by alternative enterprises and by changes within the dairy enterprise itself."

**Proceedings of the conference of the American Society of Farm Managers and Rural Appraisers and the Appraisal Institute of Canada** (*Jour. Amer. Soc. Farm Mgrs. and Rural Appraisers*, 4 (1940), No. 3, pp. [2]+158, figs. 10).—Included are the following papers with discussions thereon presented at the conference held at Winnipeg, Man., June 25-27, 1940: The Need for and Proper Basis of a Sound Appraisal System, by R. R. Hudelson (pp. 18-31) (Univ. Ill.); Rural Appraising—Panel Discussion, conducted by T. D. Morse (pp. 31-34); Advance Preparation for Making an Appraisal, by C. N. Rogers (pp. 35-37); Appraisal Field Inspection, by H. B. Sommerfeld (pp. 38-50); Appraisal Plats, by H. Pike (pp. 51-55); The Earning Statement, by W. J. Smith (pp. 56-60); Comparative Adjustments, by E. E. McAnelly (pp. 61-65); The Appraisal Report, by E. Walley (pp. 66-68); Appraisal Reports, by H. C. Hall (pp. 68-70); Analyzing Appraisals Made by the American Appraisal System, by C. U. Jett (pp. 70-74); The Synthesis of Materials for Appraising, by C. H. Hammar (pp. 74-104) (Univ. Mo.); Farm Management in Relation to Rural Appraisal, by H. C. M. Case (pp. 104-112) (Univ. Ill.); Appraising Raw Lands in Western Canada, by W. E. Hobbs (pp. 112-137); The Appraisal of Undeveloped Land Which is Part of a Developed Farm Unit, by J. W. Canfield (pp. 137-141); Progress of Appraisal Technique and Practice in Western Canada, a symposium by F. W. Gulland, H. M. Morrison, A. R. Purchase, and W. J. Smith (pp. 141-147); and Development of Rural Appraisal Technique and Progress During the Last Few Years, by D. H. Doane (pp. 148-158).

**Eighth annual report of the Farm Credit Administration** (*U. S. Dept. Agr., Farm Credit Admin., Ann. Rpt.*, 8 (1940), pp. VI+292, figs. 21).—This report to the House of Representatives covers the operation of the farm mortgage credit system—Federal land banks, national farm loan associations, Federal Farm Mortgage Corporation, and Land Bank Commissioner loans; the production credit system—production credit corporations and credit associations; Federal intermediate credit banks; banks for cooperatives; emergency crop and feed loans; organizations in liquidation—regional agricultural credit corporations, loans to purchase stock in Agricultural Credit Corporations, Agricultural Marketing Act revolving fund, joint stock land banks, and joint stock land banks in receivership; and the several divisions of the Washington office.

The research work of the Administration is described.

**Distribution of the total amount of short-term farm loans outstanding in Ohio from five lending agencies**, P. S. ECKERT (*Ohio State Univ., Dept. Rural Econ. and Rural Sociol. Mimeog. Bul.* 138 (1941), pp. [1]+13, figs. 4).—Tables and maps show by counties the amounts outstanding June 30, 1939, on loans made by banks, production credit associations, the Farm Bureau Agricultural Credit Corporation, livestock marketing corporations, the U. S. D. A. Farm Security Administration, and the five agencies combined, and also the percentages each was of the total outstanding loans of the five agencies.

**The farmer's taxes, new and old**, M. W. ENGLISH (*Washington, D. C.: Natl. Highway Users Conf.*, [1941], pp. 51, figs. 15).—In a survey made in from 3 to 5 counties, total 71 counties, in California, Colorado, Indiana, Louisiana, Maryland, Minnesota, Missouri, New Hampshire, New Jersey, New Mexico, New York, Ohio, South Carolina, Tennessee, and Washington, the receipts from gasoline taxes and motor registrations averaged 80 percent of the receipts from property taxes of farmers, ranging from 37 to 149 percent in the States studied. With an increase of  $\frac{1}{2}$  ct. per gallon in the Federal gasoline tax, it is estimated the average will be 85 percent and with a 1 ct. increase 96 percent.

**Index of the laws pertaining to co-operation** (*Works Prog. Admin. New York City [U. S.]*, Ser. A, pt. 1 [1938], pp. [2]+X+42).—This is the first of a

series of publications planned by the U. S. Works Progress Administration on cooperative organizations engaged in various types of economic activity. Federal, State, and Territorial laws in the United States are listed.

**Abstracts of the laws pertaining to cooperation in the United States of America, its possessions and territories** (*Fed. Works Agency, Work Proj. Admin. New York City, Ser. A, pt. 2* (1940), pp. [3]+VIII+350).—This is the second publication of the series noted above.

**Legal phases of cooperation** (*Fed. Works Agency, Work Proj. Admin. New York City, Ser. A, pt. 3* (1941), pp. [5]+X+242+[1]).—This third volume of the series noted above includes 265 references—general and on agricultural cooperation, consumer cooperation, credit cooperation, producers' cooperative associations, cooperative utilities, cooperative insurance, and cooperative education and recreation. An index of names and organizations, geographical and subject indexes, and an appendix showing the subsequent legislative action on the acts or proposed acts, are included.

**Farmers' mutual fire insurance companies in West Virginia**, M. A. ABRAHAMSEN (*West Virginia Sta. Bul. 302* (1941), pp. 43, figs. 2).—This study was based chiefly on information as to methods of organization and operation of farmers' mutual fire insurance companies secured by interviews with each company, from financial records for each company obtained from the insurance department of the State auditor's office, and information furnished by approximately 600 farmers. The development of such companies, the trends in business operation, membership, policies, amount of insurance, etc., are described. Analysis is made of the kinds of property insured, hazards covered, risk classification, methods of collecting money, term of policies, reinsurance and concurrent insurance, risk inspection, salary and compensation practices, territory of operation, and the general operating practices—educational work, property valuation, maximum limits per single risk, adjustments, boards of directors, etc. Suggestions are made as to improvements of operating practices.

Fifteen of the 23 farmers' mutual fire insurance companies that had been incorporated in the State were active in 1939. The average amount of insurance in force, 1935-39, was \$70,411,531. The income per \$100 of insurance in force was 39.6 ct., and the fire loss 15.6 ct. In 1939, there were nearly 37,000 members holding about 43,000 policies amounting to \$76,801,000. Of the insurance in force, 70.8 percent was on rural and 29.2 percent on urban property. Only 10 of the companies insured losses due to lightning and only two companies insured against windstorm and hail. Five companies classified risks in detail, five used the system of partial classification, and five did not classify. Four companies operated on the deferred assessment basis, six on advanced assessments, and five on advanced premiums. Seven companies used perpetual policies, one a 1-yr. policy only, and the others policies for varying periods. Only four companies followed the practice of reinsuring their risks, and only two companies accepted other risks for reinsurance.

Ten companies reported writing concurrent insurance within their territory, and one such insurance outside its operating territory. Two companies made yearly risk inspections, two no inspections, and the remainder inspections at periods of from 3 to 5 yr. or from "time to time." Seven companies paid agents commissions and eight paid a flat fee or some modification of such procedure. In 6 counties 1 or 2 companies operated, in 9 counties 3 or 4 companies, in 33 counties 5 or 6 companies, and in 7 counties 7 or 8 companies.

"In general, it seems that the future of farmers' mutual fire insurance in West Virginia will depend primarily upon three factors and the ability of leadership to make adjustments in accordance with these factors. These factors are:

"(1) Giving attention to and incorporating all possibilities for increased efficiency and better service in the performance of various operating practices.

"(2) Eliminating costly and unnecessary duplication in services resulting from overlapping in the territories served by mutual companies (such duplication tends to increase costs to policyholders and also may result in inadequate and ineffective service).

"(3) Giving further attention to means of increasing policyholder participation in company operation and to bring about increased intercompany cooperation on all problems confronting farmers' mutual fire insurance companies."

**Accounting for farmers' grain companies, J. R. RANDALL** (*Jour. Accountancy*, 72 (1941), No. 5, pp. 437-447).—Accounting and auditing procedures applicable to farmers' grain companies are described. Illustrative forms are included.

**Farm sales of Ohio milk through different outlets.—II, Akron-Canton Area: Carroll, Columbiana, Holmes, Medina, Portage, Stark, Summit, Tuscarawas, and Wayne Counties, C. G. McBRIDE and R. W. SHEERMAN** (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul.* 131 (1941), pt. 2, pp. [2]+45, figs. 16).—This study is the second of a series previously noted (*E. S. R.*, 84, p. 265).

**Marketing peanuts and peanut products, H. J. CLAY** (*U. S. Dept. Agr., Misc. Pub.* 416 (1941), pp. [2]+124, figs. 44).—This describes the commercial types and varieties of peanuts; the harvesting, curing, picking, threshing, and storing of the crop; the methods of marketing farmers' stock peanuts and the grades for such peanuts in different areas; the difference in prices for different grades; government control measures affecting the peanut enterprise; the operation of cleaning and shelling plants; grades and Federal inspection of shelled and cleaned peanuts; methods of disposing of such peanuts; transportation; the geographic distribution of shipments; the character of receipts in different markets; the Federal market news reports; the various peanut products; peanuts as a feed for hogs; foreign production, imports, and exports of peanuts and peanut oil; and other phases of the marketing of peanuts and peanut products. Lists of the literature cited and of the U. S. Department of Agriculture publications relating to peanuts and peanut products are included.

**Market quality of Kansas potatoes as determined by Federal inspection, F. L. PARSONS.** (Coop. U. S. D. A.). (*Kansas Sta. Bul.* 298 (1941), pp. 36, figs. 12).—The development of potato inspection work in the State, proportion of potatoes inspected, varieties shipped, classification by grades, defects, decay as a grade defect, cleanness, size, methods of loading, etc. are discussed. The appendix includes the U. S. standards for potatoes.

During the period 1935-39 about one-half of the potatoes shipped out of the State were Federally inspected. Thirty-two percent of the inspected potatoes during the period 1930-39 were U. S. No. 1, 51.4 percent U. S. Commercial, 12.7 percent U. S. No. 2, 3.1 percent unclassified, and 0.8 percent mixed. The percentages of the inspected potatoes showing different grade defects were: Cuts 54.9, second growth 43.2, scab 41.2, misshapen 31.7, wireworm injury 28.2, growth cracks 24.7, sun injury 22.9, bruises 19.9, mechanical injury 16.3, and other injury 16.2. No decay was reported for 47.1 percent of the cars inspected, 0.5 percent or less for 24.7, 0.5 to 1 percent for 25.7, and over 1 percent for 2.5. Only 19 percent of the U. S. No. 1 potatoes were graded as "clean" and 0.2 percent as "dirty." For U. S. Commercial potatoes, the percentages were 9.8 and 16.4, respectively, and for U. S. No. 2 potatoes, 6.7 and 42.7 percent, respectively. Eighty percent of the unclassified potatoes were so graded because of decay in excess of 1 percent. Approximately 75 percent of the potatoes inspected were designated as 1½ in. minimum size. Over 94 percent of the cars were loaded "summer style," but there is a growing tendency to use the "pyramid" style.

**Farmers' marketing and purchasing associations in Tennessee, B. D. RASKOFF and P. W. VOLTZ** (*Tennessee Sta. Bul.* 177 (1941), pp. 59, figs. 13).—This bulletin, which is a joint undertaking with the Tennessee Valley Authority, is part of a coordinated study in the Tennessee River drainage basin, conducted by the T. V. A. and land-grant colleges in the area. Schedules were obtained from the 62 farmers' marketing, and the 30 purchasing, cooperatives active in 1938 in Tennessee. The field data were obtained directly from association managers and records of the associations. County agents provided general information regarding the developments in their respective counties. In the discussion the marketing associations are divided into: Regional cooperatives, 5 in number; dairy cooperatives consisting of 2 milk bargaining associations, 5 creameries, and 2 cheese factories; fruit and vegetable cooperatives consisting of 9 strawberry, 6 sweetpotato, and 1 county growers' associations; livestock, wool, and poultry associations consisting of 4 livestock breeders', 2 poultry, and 25 livestock shipping and wool associations; and 1 grain-marketing association. The purchasing cooperatives consisted of 1 regional association, 3 independent local units, and 35 county farm bureaus and affiliates. The discussion of each type of cooperative includes sections on history, area served, organizational structure, financial analysis, and problems and programs. Generalizations as to Tennessee cooperatives are discussed under the following headings: Desirability of incorporation, necessity for sound financing, adequate compensation of officers and employees, improvement in membership relations, need for satisfactory records, possibilities of success, weaknesses of inactive associations, and opportunities for further development in Tennessee.

**Report of the administrative official in charge of surplus removal and marketing agreement programs, 1940** (*U. S. Dept. Agr., Surplus Market. Admin. Rpt.*, 1940, pp. 83).—This report to the Secretary of Agriculture, for the year ended June 30, 1940, covers the activities of the Federal Surplus Commodities Corporation and the Division of Marketing and Marketing Agreements. The role of surplus removal and marketing agreement programs; the surplus removal programs—direct purchases and distribution, surpluses for school lunches, the Food Stamp and Cotton Stamp Plans, wider outlets for surpluses, and encouragement of export sales; the marketing agreement programs and the improvement of markets for different agricultural products; and the results as to transportation rates obtained by the U. S. Department of Agriculture through negotiations and through formal actions before the Interstate Commerce Commission, are described and discussed.

**Economic problems of the locker plant industry, R. J. EGGEET.** (Kans State Col.). (*Quick Frozen Foods*, 4 (1941), No. 2, pp. 16-17, 32-34).—This article is based chiefly on a study in progress at the Kansas Experiment Station. It describes the increase in the number of locker plants in Kansas and the United States during recent years. The possible savings by use of lockers are illustrated by preliminary figures comparing the costs of using locker service for beef and the costs of purchases from delivery and credit, cash and carry, and supermarkets in Manhattan, Kans., during March 1941. The further savings possible by taking advantage of seasonal price variations of different grades of steers, fat hogs, and fat lambs are discussed. The advantages and disadvantages of the use of locker plants are compared, the Kansas findings being supplemented by findings in studies in Minnesota and Illinois.

**Trends in market prices for Montana farm and ranch products, H. G. HALCROW and J. G. DIAMOND.** (Coop. U. S. D. A.). (*Montana Sta. Bul.* 394 (1941), pp. 21, figs. 18).—Tables show: (1) The average yearly prices, 1910-40 (shorter periods in some cases), received for crops commonly grown in the State

and for different kinds of livestock and livestock products, and (2) the average monthly prices, 1921-40. One series of charts shows the index numbers of the yearly prices, 1910-40, of the different products, and another series the monthly average prices, 1921-40, and also for wheat and beef cattle for the periods 1910-40 and 1931-40.

**Statistical summary of prices received by Montana farmers and ranchers by months, August 1909-December 1940, H. G. HALCROW.** (Coop. U. S. D. A. et al.). (*Montana Sta. Mimeog. Cir. 33* (1941), pp. [2]+71, figs. 2).—This circular presents the statistical material upon which the bulletin noted above is based. It includes tables showing the monthly average prices received by Montana farmers and ranchers, and the index of such prices, for the major agricultural products during the period August 1909-December 1940. The method used in computing the index numbers is described.

**Fixed prices for agricultural commodities (Washington, D. C.: Chamber Com. U. S., 1941, pp. 22).**—This report of the Agricultural Department Committee of the Chamber of Commerce of the United States is entitled *An Analysis of Conditions Fostering Price-Fixing Proposals and a Survey of Price-Fixing Experience in Different Countries*. The committee's recommendations are: "In view of the record of failure of attempts at price fixing for agricultural products due to economic dislocations and restrictions on individual freedom and initiative, the committee recommends continued adherence to the long-established national policy under which price determination is accomplished through a system of freely operating marketing agencies. In any attempts, arising from a national emergency, to extend price control to a wide range of agricultural and non-agricultural commodities, the committee recommends that, in view of the inequalities produced by former attempts at price fixing, the method of control adopted be such as will insure to agriculture economic equality with labor and industry."

**An appraisal of index numbers of prices farmers pay, J. DEAN and M. H. WISE** (*Jour. Amer. Statis. Assoc.*, 36 (1941), No. 214, pp. 210-218, fig. 1).—This revision of a paper presented before the American Statistical Association at Chicago, December 27, 1940, discusses the U. S. D. A. Index of Prices Farmers Pay, and suggests how it might be improved.

"In view of the desirability of using Fisher's 'ideal' formula for computing the index, the possibility of obtaining new weights each year by means of permanent, small stratified samples merits consideration. On the basis of the extensive Consumer Purchases Study, it might be possible to select a small number of families typical of each major region, farming type, and income group and to have these families keep records of their expenditures. The more homogeneous the subgroups the smaller may be the number of families sampled. Construction of subsidiary cost of living and cost of production indexes for various regions and types of farming seems desirable, even if the weights must be based on very small samples.

"Tailoring this, revision of the weights every few years seems desirable. The base period should probably be shifted to a more recent period, possibly 1935-39, if this becomes permissible under the revised statutes. Introduction of new commodities as soon as they assume importance in the budget, regardless of whether their prices are stable, is recommended. Although no satisfactory theoretical solution exists for the problem of the price at which the new commodity should be introduced, it would seem logical to have regard both for its price behavior while it was growing in importance and for the price of the commodities it supplements. Expression of prices of certain commodities in terms of units of service (e. g. tire miles and truck ton miles) rather than in terms of conventional units appears to merit further consideration."

**Agricultural statistics, 1941** (*U. S. Dept. Agr., 1941, pp. [2]+731*).—This volume continues the series (*E. S. R., 84, p. 686*) and includes statistics prepared under the direction of the Yearbook Statistical Committee on grains, cotton, sugar, tobacco, fruits, vegetables, melons, tree nuts, miscellaneous crops, beef cattle, hogs, sheep, horses, mules, dairy cattle, poultry, and dairy and poultry products, foreign trade in agricultural products, farm business and related subjects, and miscellaneous subjects—forestry, weather, roads, etc.

**Crops and Markets, [October–November 1941]** (*U. S. Dept. Agr., Crops and Markets, 18 (1941), Nos. 10, pp. 221–244, fig. 1; 11, pp. 245–268, figs. 3*).—Each number includes crop and market reports of the usual types.

## RURAL SOCIOLOGY

**Larger population, more land in farms, bigger farms; but fewer farms, fewer tenants, growing more livestock, feed, F. WELCH** (*Miss. Farm Res. [Mississippi Sta.], 4 (1941), No. 10, p. 8*).—The author reports that in the 1930–40 period, Mississippi's population increased by nearly 200,000, more land was brought into farms, farms increased in size, the number of farms and of tenants declined, the number of livestock increased, and more food was produced.

**Acadian contracts in southwest Louisiana—some sociological observations, L. C. POST** (*Rural Sociol., 6 (1941), No. 2, pp. 144–155*).—"Among the Acadians and other inhabitants who live in the cotton section of Lafayette Parish and the adjoining portion of Acadia Parish in southwest Louisiana many folk customs which fall under the headings of contractual arrangements and labor agreements are in operation. No matter how complicated an agreement may be, it usually takes only a few spoken words for its consummation. Some of the details, whether stated or implied, show peculiar twists and turns which, when thoroughly understood, give an intimacy with the culture of the region that perhaps can be gained in no other way. In the adjoining rice country markedly different arrangements prevail, differences obviously based upon differences in economic patterns and culture heritages."

**The rice economy of Monsoon Asia, V. D. WICKIZER and M. K. BENNETT** (*Food Res. Inst. [Stanford Univ.], Grain Econ. Ser. No. 3 (1941), pp. XIII+358, pls. 2, figs. 28*).—This book contributes to a better understanding of far eastern food problems and should stimulate further study in the years ahead.

**Rural-urban conflict in Argentine sociological theories, W. E. MOORE** (*Pa. State Col.*). (*Rural Sociol., 6 (1941), No. 2, pp. 138–143*).—"Although rural sociology as such has received scant attention in Argentina, . . . the adaptation of European theories to the interpretation of Argentine national history has resulted in considerable attention to the role of rural-urban conflict in the course of national development."

**The complex farm-labor problem of South Africa, J. M. TINLEY**. (*Calif. Expt. Sta.*). (*Rural Sociol., 6 (1941), No. 2, pp. 126–137, fig. 1*).—"The agricultural-labor problem of the Union of South Africa is complicated by the competition between commercial agriculture and industry for labor, by racial and cultural heterogeneity, by the impact of an exchange economy upon a primitive tribal economy, by the unbalanced distribution of labor supply in relation to industry, and by the pressure of population on land. The effects of these disturbing factors are evidenced by social and economic instability, problems of health and nutrition, and low standards of living. Efforts to increase the efficiency of native agriculture are being made, but funds available are woefully inadequate. The agricultural-labor problem cannot be solved without some modifications in the entire domestic economy of South Africa."

**Trade unions in agriculture**, H. W. SPIEGEL (*Rural Sociol.*, 6 (1941), No. 2, pp. 117-125).—"Two organization drives relating to farm labor are distinguished. The first reached its peak during the first World War, but the newly won ground was completely lost during subsequent years under the impact of changing technologies and the post-war agricultural depression. . . . The stronghold of organized farm labor is limited to the West. In appraising the extent of the new organization, account must be taken of the fact that many of its members are employed in occupations not strictly agricultural. . . . Nearly 40 per cent of all hired workers in agriculture are employed on farms reporting three or more hired laborers. Industrial disputes on farms reached a peak in 1933 and have abated since then. This seems to indicate that the organization of farm labor has been helpful in developing greater skill and statesmanship in the handling of these disputes. On the national scene, the growth of organized farm labor has resulted in increasing pressure directed toward the removal of the legal disabilities of that type of labor."

**Recent changes in farm trade centers of Minnesota**, L. NELSON and E. T. JACOBSON. (Minn. Expt. Sta.). (*Rural Sociol.*, 6 (1941), No. 2, pp. 99-106).—"The impact of the depression on Minnesota rural trade centers, as measured by the change in number of business units from 1929 to 1933, showed a rather marked decline of 7.5 percent for small centers and of 2.6 percent for medium sized places, while the larger centers actually gained by the slight margin of 1.1 percent. Moreover, the small places while losing more heavily during the depression years failed to gain as rapidly from 1933 to 1937 as did the medium and larger places. A large part of the 'recovery' gains in business units was in filling stations and eating and drinking establishments. Distance from a major trade center seems to influence the growth or decline of smaller places."

### FOODS—HUMAN NUTRITION

**Needed research in food and nutrition**, J. WHITACRE. [Tex. Expt. Sta.]. (*Jour. Home Econ.*, 33 (1941), No. 9, pp. 648-650).—"A classified summary of 618 problems on which research is needed. These were suggested by home economists in response to a questionnaire issued by the research committee of the Food and Nutrition Division of the American Home Economics Association."

**Laboratory and business relationships in foods and nutrition**, C. R. FELLERS. (Mass. Expt. Sta.). (*Jour. Home Econ.*, 33 (1941), No. 2, pp. 87-93).—"An address."

**The forty-fifth report on food products and the thirty-third report on drug products, 1940**, E. M. BAILEY ET AL. (*Connecticut [New Haven] Sta. Bul.* 447 (1941), pp. 447-481).—"This annual report (E. S. R., 84, p. 271), summarizing the results of regulatory examinations for the calendar year 1940, includes notes and certain data on fruit juice beverages, milk and milk products, skunk cabbage seed and pulp, rose hips, other food products, and drugs."

[Foods and nutrition studies by the New York State Station] (*New York State Sta. Rpt.* 1941, pp. 14-16, 20).—"This is a brief progress report (E. S. R., 84, p. 693) of results obtained as to the processing of vegetable and fruit juices, the germicidal action of cabbage juice, and yeasts in fermented food products."

**Food facts and fads**, H. S. MITCHELL. (Mass. State Col. et al.). (*Jour. Amer. Dietet. Assoc.*, 17 (1941), No. 7, pp. 667-670).—"An address."

**Stability of homogenized milk in cookery practice**, H. HOLLENDER and K. G. WECKEL. (Wis. Expt. Sta.). (*Food Res.*, 6 (1941), No. 4, pp. 335-343).—"Stability to coagulation as observed in milks used in the preparation of escalloped potatoes varied with potatoes of different variety, origin, and culture. In general, homogenized milk was relatively less stable to coagulation than was unhomoge-

nized milk. The effectiveness of added sodium citrate, phosphate, or carbonate in stabilizing homogenized milk appeared to depend upon the inherent characteristics of the potato used in the preparation of the cooked product. Acidity of the potatoes, however, was not a measure of their effect on the stability of milk.

Upon mixing with hot cooked cereal, the homogenized milk showed a greater tendency to coagulation than did the unhomogenized milk. The addition of sodium citrate to the cooked cereals prevented, and the addition of salt as seasoning delayed, the coagulation of milks, either homogenized or unhomogenized, when mixed with the cereal. Preheating of the milk did not increase its stability to coagulation when added to the cereals. Calcium chloride added to cooked cereal in amounts equivalent to 0.056 and 0.028 gm. per gram of oatmeal and wheat meal, respectively, caused rapid coagulation of the added milk. It is pointed out that a similar effect would be produced by water of sufficient hardness. The curd tension of egg custard prepared from homogenized milk was lower, and the serum separation greater, than when unhomogenized milk was used. There was a lower cooking temperature and apparently a more critical cooking temperature-range for custards prepared from homogenized milk than for those from unhomogenized milk.

**Sour cream: How to prepare and use it at home** (*U. S. Dept. Agr. Leaflet 213* (1941), pp. 8).—Directions for the home preparation of sour cream and recipes for its use in making dressings, as a garnish, and as an ingredient in baking and cooking are given.

**Why eggs are classified as a protective food**, R. V. BOUCHER. (Pa. State Col.). (*U. S. Egg and Poultry Mag.*, 47 (1941), No. 8, pp. 470-473, 512, figs. 8).—This paper, presented as a popular talk, discusses the nutritive value of eggs in terms of their contribution of protein, minerals, and vitamins.

**Chemical and histological studies of the disintegration of cell-membrane materials in vegetables during cooking**, J. I. SIMPSON and E. G. HALLIDAY (*Food Res.*, 6 (1941), No. 2, pp. 189-206, pls. 6).—To observe the effect of cooking on cell-membrane materials, chemical, histological, and microchemical studies described in detail and concerned with pectic substances and cellulose, were made on carrots and parsnips in the raw state (after treatment with alcohol to inhibit enzyme activity) and as steamed for different intervals. The data presented indicate that steaming (for 20 and for 45 min.) caused a progressive increase in the pectin content at the expense of protopectin which decreased in amount. These changes were accompanied by a slight increase in pectic acid (or pectates). Apparently some destruction of the pectin occurred, since there was a decrease in total pectic substances and since the decrease in protopectin far exceeded the increase in pectin. These changes were all slightly greater in carrots than in parsnips. Histological studies were made of paraffin sections of both raw and steamed vegetables, one series being stained with light green to show cellulose and another with ruthenium red to show pectic substances. Photomicrographs presented of representative sections of xylem and phloem tissues of the raw vegetables and those steamed 45 min. indicated that the cell walls of the steamed samples were less thick and less continuous than those of the raw ones. This disintegration is considered as an important factor in the loss of rigidity of vegetables during steaming. Microchemical tests on paraffin sections of both vegetables showed that steaming caused alterations in the cellulose component of the cell membranes.

**Calcium firming of canned whole tomatoes**, Z. I. KERTESZ. (N. Y. State Expt. Sta.). (*Canner*, 93 (1941), No. 24, pp. 13-14, fig. 1).—This brief survey points out that in 1941 approximately 1,000,000 cases of tomatoes were packed with the addition of calcium (*E. S. R.*, 81, p. 449), this being applied chiefly in

the form of combination table salt-calcium chloride tablets now manufactured in three different sizes for No. 2, 2½, and 10 size cans.

**Freezing preservation of fruits and vegetables**, H. D. BROWN. (Ohio State Univ.). (*Quick Frozen Foods*, 3 (1941), No. 8, pp. 14-15, 33-35, figs. 3).—An address.

**Nutritive value of quick frozen foods**, F. FENTON. (Cornell Univ.). (*Refrig. Engin.*, 42 (1941), No. 2, pp. 140, 142).—A brief summary of a study noted earlier (E. S. R., 85, p. 571).

**Factors that affect quality in frozen lima beans**, J. G. WOODROOF and J. O. TANKERSLEY. (Ga. Expt. Sta. and Univ. Tenn.). (*Food Indus.*, 13 (1941), No. 4, pp. 53-56, figs. 6).—Tests have shown that maximum preservation of color, flavor, and nutritive value is attained only when all operations—shelling, grading, blanching, and freezing—are carried out in quick succession and as rapidly as possible. Freezing was found to reduce the cooking time of lima beans by about 10 percent. The weight and volume of the frozen beans increased about 10 percent upon cooking. Season and growing conditions were found to have a very great influence on the time required for cooking lima beans.

**How locker plants control quality**, H. H. PLAGGE. (Iowa Expt. Sta.). (*Food Indus.*, 13 (1941), No. 8, pp. 37-39, 40, figs. 3).—An address.

**And now—quick frozen pies, cookies, cakes, and biscuits**, G. L. SUNDERLIN and O. D. COLLINS. (Purdue Univ.). (*Quick Frozen Foods*, 3 (1941), No. 7, pp. 13, 44).—Freezing in airtight containers at -10° F. (and 0°) was found to be a satisfactory means of preserving roll dough, biscuit dough, pastry, pies, cookie dough, and cake batters. Maximum periods for successful storage varied from 1 mo. for baking powder biscuits and fresh peach pie to 4, 9, and 12 mo. for cake batter, pastry, and cookie doughs, respectively. Recipes used in the experiments on frozen batters and doughs are given.

**Title 21—Food and drugs.—Chapter I—Food and Drug Administration.**  
**Part 15—Wheat flour and related products; definitions and standards of identity**, W. B. MILLER (*Natl. Arch. U. S., Fed. Register*, 6 (1941), No. 103, pp. 2574-2582).—Findings of fact and regulations promulgated in the final order issued May 26, 1941, by the Acting Federal Security Administrator under the provisions of the Federal Food, Drug, and Cosmetic Act are presented "in the matter of a definition and standard of identity for each of the following foods: (A) flour, white flour, wheat flour, plain flour; (B) enriched flour; (C) bromated flour; (D) enriched bromated flour; (E) durum flour; (F) self-rising flour, self-rising white flour, self-rising wheat flour; (G) enriched self-rising flour; (H) phosphated flour, phosphated white flour, phosphated wheat flour; (I) whole wheat flour, graham flour, entire wheat flour; (J) bromated whole wheat flour; (K) whole durum wheat flour; (L) crushed wheat, coarse ground wheat; (M) cracked wheat; (N) farina; (O) enriched farina; (P) semolina."

Under the promulgated regulations of this order, which becomes effective January 1, 1942, enriched flour conforms to the definition and standard of identity prescribed for flour "except that: (a) It contains in each pound not less than 1.66 mg. and not more than 2.5 mg. of vitamin B<sub>1</sub>, not less than 1.2 mg. and not more than 1.8 mg. of riboflavin, not less than 6 mg. and not more than 24 mg. of nicotinic acid or nicotinic acid amide, not less than 6 mg. and not more than 24 mg. of iron (Fe); (b) vitamin D may be added in such quantity that each pound of the finished enriched flour contains not less than 250 U. S. P. units and not more than 1,000 U. S. P. units of vitamin D; (c) calcium may be added in such quantity that each pound of the finished enriched flour contains not less than 500 mg. and not more than 2,000 mg. of calcium (Ca), except that enriched flour may be acidified with monocalcium phosphate irrespective of the

minimum limit for calcium (Ca) herein prescribed; (d) it may contain not more than 5 percent by weight of wheat germ or partly defatted wheat germ; and (e) in determining whether the ash content complies with the requirements of this section allowance is made for ash resulting from any added iron or salts of iron or calcium. Iron and calcium may be added only in forms which are harmless and assimilable. The substances referred to in paragraphs (a) and (b) may be added in a harmless carrier which does not impair the enriched flour; such carrier is used only in the quantity necessary to effect an intimate and uniform admixture of such substances with the flour."

The same enrichments are prescribed for enriched bromated and enriched self-rising flours. The definition and standard of identity of enriched farina prescribes minimum supplements of vitamin B<sub>1</sub>, riboflavin, nicotinic acid, and iron, and minimum optional additions of vitamin D and calcium corresponding to the minima noted above. In addition enriched farina may contain not more than 8 percent by weight of the optional ingredient wheat germ or partly defatted wheat germ; and not less than 0.5 percent and not more than 1 percent by weight of the optional ingredient disodium phosphate.

**Title 21—Food and drugs.—Chapter I—Food and Drug Administration. Part 15—Wheat flour and related products; definitions and standards of identity.** P. V. McNUTT (*Natl. Arch. U. S., Fed. Register*, 6 (1941), No. 234, pp. 6175-6176).—It is stated that the supply of riboflavin in forms suitable for addition to the enriched foods noted above is not sufficient to permit their production on a scale that would meet current needs but that such supply will be available July 1, 1942. "It is ordered, therefore, that the effective date of the requirements of said order that each pound of enriched flour, enriched bromated flour, enriched self-rising flour, and enriched farina contain not less than 1.2 mg. of riboflavin be postponed to July 1, 1942." This order was issued by the Federal Security Administrator November 29, 1941.

**The milling aspects of fortified flour.** D. W. KENT-JONES and A. J. AMOS (*Lancet [London]*, 1941, I, No. 23, p. 731).—Referring to the British Government's scheme of enriching white flour through the addition of 0.2 gm. of synthetic vitamin B<sub>1</sub> to each sack (280 lb.) of flour, the authors point to the difficulty of uniform mixing of such disproportionate amounts and indicate that a more satisfactory method has been devised which involves the use of a concentrate. This is prepared by mixing 1 oz. of thiamin, dissolved in water, with a thin batter made of water and a 140-lb. portion of flour. This mixture is spray dried and the dried product incorporated at the rate of 1 oz. per sack to give the necessary  $\frac{1}{140}$  oz. of the vitamin per sack.

The British proposal to add 8 oz. of calcium carbonate per sack presents no mechanical difficulties, but this calcium compound, because of its alkalinity, has caused some trouble since it reduces the acidity of the dough to a point where it is at times difficult to control the development of bacteria of the mesentericus group responsible for rope. It is further pointed out that there is some evidence that the calcium carbonate may result in the destruction of some of the thiamin during the baking process. Commenting on the plan (noted above) in use in the United States for enrichment of flour, the following is said:

"This presents a complex and difficult problem for all concerned, particularly the miller and the cereal chemist, and most people will be relieved that, so far at any rate, the authorities in England have not followed up 'fortification' with the same enthusiasm."

**National flour for bread: M. R. C. specifications** (*Brit. Med. Jour.*, No. 4195 (1941), pp. 828-829).—On the basis of the recommendations of the Medical Research Council (British) (*E. S. R.*, 84, p. 841), the Ministry of Food fixed the

degree of extraction at 85 percent and defined the flour as one obtained (1) by rearrangement of the milling machinery to produce a flour containing 85 percent of the wheat or (2) by addition to the white flour (73 percent extraction), obtained in the ordinary milling process, of combinations of the other fractions of the wheat. Comparative analyses, showing fiber, ash, protein, vitamin B<sub>1</sub>, calcium, and phosphorus, of these two types (85 percent extraction), a white flour (73 percent extraction), and a whole-wheat flour are presented. Until the machinery adjustments necessary for the production of the first type of 85-percent extraction flour can be made, the second type is recommended for adoption, this flour, as estimated from the comparative analyses, to contain not less than 1 International Unit of vitamin B<sub>1</sub> per gram and less than 0.9 percent of fiber (15 percent moisture basis). It is further recommended that flours be enriched with calcium carbonate to the extent of 7 and 14 oz. per sack (280 lb.) for the 73- and 85-percent extractions, respectively. The addition of iron salts is not recommended because of their possible deleterious effects on other nutrients present.

**National flour** (*Lancet* [London], 1941, I, No. 22, pp. 703-704).—Essentially noted above.

**Wheat "peeling" process yields high-vitamin flour and bread** (*Food Indus.*, 13 (1941), No. 5, pp. 70-71, figs. 4).—The flotation method borrowed from mining practice and developed by T. Earle as a process for removing the rough outer hulls from wheat kernels is described. This patented process consists in conducting the rough cleaned wheat through a series of 10 flotation cells into which wheat and water are fed in definite proportions and in which rubber-covered impellers vigorously rub the wheat against the rubber-lined sides of the cells, thus peeling off the wheat hulls. A flotation agent, pine oil, added to cause a froth, carries off the freed wheat hulls, while the peeled wheat carried along to the end of the chain of cells is discharged into a vibrating screen that removes most of the water. This peeled wheat, subsequently dried and tempered, is ground very fine, giving a golden-colored flour that retains most of the minerals and vitamins of the original wheat grain, but is lower in fiber content than 100-percent whole-wheat flour. Analyses of the flour gave the following values: Moisture 11.5, protein 15.3, minerals 1.63, crude fat 1.78, and crude fiber 1.38 percent, with a vitamin B<sub>1</sub> value of 965 International Units per pound. "Staff" flour (and bread) is the trade designation for this product.

**Sugar rendering of lard increases stability**, S. BULL. (Univ. Ill.). (*Food Indus.*, 13 (1941), No. 4, pp. 48-49, 97, fig. 1).—The addition of 0.5 percent of dextrose to fat kettle-rendered on a laboratory scale or steam-rendered commercially resulted in a lard with greater stability than the control product obtained without the addition of sugar. The former product had a slightly dark color and a slight odor and flavor of caramel. Decolorization of the sugar-rendered lard with fuller's earth produced a white product, which was less stable than the unbleached product yet more stable than the untreated lard. The degree of stability was judged by the rate of rancidity development upon bubbling air through the hot, melted fat under standard conditions. Cakes and pie crusts of satisfactory quality were obtained with the use of both the bleached and unbleached sugar-rendered lards.

**Nutrition in defense**, R. OVERSTREET. (Fla. Expt. Sta.). (*Citrus Indus.*, 22 (1941), No. 9, p. 19).—A brief statement noting a few of the available findings on the present state of the Nation's nutrition, and citing the simple diet recommendations of the National Nutrition Committee for Defense as a yardstick for family diets.

The national nutrition outlook, H. S. MITCHELL. [Mass. Expt. Sta.]. (*Jour. Home Econ.*, 33 (1941), No. 8, pp. 537-540).—An address.

The school lunch program and agricultural surplus disposal, H. M. SOUTHWORTH and M. I. KLAYMAN (*U. S. Dept. Agr., Misc. Pub.* 467 (1941), pp. 1-66, figs. 8).—"The supplying of surplus foods through the Surplus Marketing Administration is the primary concern of this report. Against a background discussion of the school-lunch movement in terms of nutritional need among children in the United States and previous experience with school feeding both here and abroad, it describes the S. M. A. program in operation, with emphasis upon its integration with the activities both of W. P. A. and of the other agencies and organizations, public and private, local, State, and national, that are active in school-lunch work, and attempts an evaluation of the program both as agricultural policy and as a contribution to child welfare."

From the viewpoint of agriculture, the program is considered to provide a particularly efficient method of surplus disposal, with little danger that the foods purchased will replace commercial sales that might otherwise have been made, but on the contrary a creation of new commercial sales of foods to supplement the surplus commodities used in these projects. From the viewpoint of child welfare, the program helps arouse public interest in child malnutrition, stimulates thousands of communities to local action, and brings together a wide range of organizations and agencies for coordinated effort toward solving the problem. "Greater contributions to child welfare could be made by the program if continued expansion of supplementary food-supplying projects were made with greater emphasis on nutritive value as a criterion in selecting foods."

The student dietitian: An experiment in cooperative education, M. A. OHLSON. (Iowa State Col.). (*Jour. Amer. Dietet. Assoc.*, 17 (1941), No. 7, pp. 644-649).—An address.

Feeding our old fashioned children, C. A. and M. M. ALDRICH (*New York: Macmillan Co.*, 1941, [3. ed., rev.], pp. [XI]+112, pls. 6).—In this revision of the book entitled *Cultivating the Child's Appetite* (E. S. R., 59, p. 189), the text has been rewritten to embody recent scientific evidence which "offers new solutions to feeding difficulties by diverting us from our absorption in food and turning us toward the children who do the feeding." Developments in biology, nutrition, mental hygiene, psychology, growth, and development are made use of to show "how children naturally go about the process of eating, and how this agreeable habit may be fostered."

Studies of blood of high school girls, J. M. LEICHSFENRING, E. G. DONELSON, and L. M. WALK. (Minn. Expt. Sta.). (*Amer. Jour. Diseases Children*, 62 (1941), No. 2, pp. 262-272).—In a study of the blood of 258 normal high school girls ranging in age from 12 to 19 yr., counts and measurements of the red and white cells were made and hemoglobin content was determined. The hemoglobin values, which averaged  $12.21 \pm 0.80$  gm. per 100 cc. of blood, were lower for the 14-, 15-, 16-, and 17-year-old groups than for the 12- to 13-year-old group, but rose again to the 12- to 13-year-old level in the 18-year-old group. The values for the red cell count, averaging  $4,150,000 \pm 240,000$  cells per cubic millimeter, tended to follow those for hemoglobin content. The mean value for white cell count was  $7,340 \pm 1,770$  cells per cubic millimeter. The proportion of reticulocytes averaged  $1.08 \pm 0.65$  percent, and the mean diameter of the red cells was  $7.90 \pm 0.20\mu$ . The mean percentage of reticulocytes showed a gradual decrease with age, whereas the mean red cell diameter showed a slight increase. The mean values for the white cell count were not influenced by the age of the subjects. Of the two factors which may affect hemoglobin values and red cell counts in

adolescent girls, that is, the rate of growth and the periodic loss of blood, the data suggest that growth rate exerted the greater influence on the blood picture. The hemoglobin values, the red cell counts, and the percentages of young red blood cells were found to vary with the periods of the menstrual cycle.

The composition of gains made by rats on diets promoting different rates of gain, M. PICKENS, W. E. ANDERSON, and A. H. SMITH (*Jour. Nutr.*, 20 (1940), No. 4, pp. 351-365).—Five rates of gain were produced by dietary adjustment. These included rapid early gains of rapidly growing rats, early gains of normal (stock) rats, two rates of retarded growth, and an intermediate rate of gain obtained at a mature age during the recovery of stunted animals. At 42, 110, 230, and in the two stunted groups at 160 days also, animals were killed and analyzed for moisture, lipide, protein, and ash contents of their bodies, and the data for the individual animals were compared statistically. The results indicated that the early growth gains of the rapidly growing and normal groups were rapid and contained a preponderance of protein over fat, while later gains were made more slowly and involved the accumulation of large quantities of fat. The slight early gains of stunted animals also represented an accumulation of more protein than fat, but after realimentation with consequent rapid increase in weight, the animals added more fat than previously. "No single generality, therefore, relates rate of growth and composition of gains, but other factors such as age and nature of the diet appear to influence the composition of the gains." At the end of the experiment the fat-free matter of the bodies of all four groups was practically identical in composition. The iodine number of the body fat rose sharply between the first and fourteenth days, but did not significantly differ thereafter for animals of different age and dietary history.

Choline and epithelial hyperplasia in the forestomach of rats, G. R. SHARPLESS (*Soc. Expt. Biol. and Med. Proc.*, 45 (1940), No. 1, pp. 487-488).—A further study of the factors responsible for the prevention of hyperplasia in the forestomach epithelium of the rat (E. S. R., 84, p. 705) is reported, with the conclusion that one of the factors essential is choline. Of a group of 26 young rats fed for 6 weeks a basal diet of white flour 89, salts 5, butterfat 5, nicotinic acid 0.5, and cystine 0.5 percent supplemented with riboflavin, thiamin chloride, and pyridoxine hydrochloride to the extent of 0.4, 1.0, and 2.0 mg. percent, respectively, 18 developed typical lesions, while of 33 litter mates on the same diet supplemented with 0.15 percent of choline chloride only 5 had slight lesions. This observation is thought to explain why protein tends to prevent and fat to increase the hyperplasia of the forestomach epithelium, inasmuch as methionine and perhaps other amino acids have a cholinelike action and choline is required for normal fat metabolism or transport.

Gastro-intestinal motility in the albino rat after administration of amphetamine sulfate, E. SMITH and K. E. PENROD. (Iowa State Col.). (*Soc. Expt. Biol. and Med. Proc.*, 47 (1941), No. 2, pp. 418-419).—Measurements were made of the action of various doses of the drug on effective peristalsis and egestion time in intact animals and of the action on isolated segments of the colon. The results of these tests led to the conclusion that "amphetamine sulfate relaxes the stomach and small intestine, constricts the pylorus, and delays the passage of material along the gastrointestinal tract. Isolated segments of colon are stimulated by minimum effective doses; larger doses inhibit."

The effect of heat on the availability of the iron of beef muscle, H. G. OLDHAM (*Jour. Nutr.*, 22 (1941), No. 2, pp. 197-203, figs. 2).—Young rats made anemic on a basal milk diet were continued on this diet supplemented with copper and manganese and given daily supplements of ferric chloride, oven-dried (at 80° C.) meat, or vacuum-dried meat in amounts to furnish equal

amounts of iron. The response of the animals, as judged by the amount of hemoglobin formed, was the same with the supplement of oven-dried meat as with the ferric chloride, but significantly less hemoglobin was formed when vacuum-dried meat was fed. These results indicated that "heat renders the iron of beef muscle, of which at least 50 percent is in the organic form, as available for hemoglobin synthesis as the iron of an inorganic iron salt." This observation confirmed earlier results (E. S. R., 80, p. 559) showing that a normal infant could utilize the iron of cooked beef muscle as well as that of an iron salt.

**The iron requirement of adults,** A. P. BARER and W. M. FOWLER (*Jour. Amer. Dietet. Assoc.*, 16 (1940), No. 8, pp. 769-778).—Forty-two patients with various pathological conditions, none of which involved blood loss, served as subjects in metabolism tests in which iron, nitrogen, and phosphorus balances were determined. Three carefully weighed diets, including neither liver nor spinach, were served to the patients. The average caloric value of the diets was 152 percent of the basal requirement, the average protein intake was 1.11 gm. per kilogram of body weight, and the average daily iron intake, as calculated from food tables and food consumption records, was 11.9 mg., with a range of 8.25-19.98 mg. Following a 3-day adjustment period on the diets, stool and urine collections were made, each of the pooled specimens being analyzed for nitrogen, phosphorus, and iron. Blood hemoglobin values were determined by the Newcomer method. The balance figures reported without any indication of the relative fecal and urinary excretions indicated that diets calculated as containing from 3.81 to 6.76 mg. of iron per day resulted in negative iron balance, whereas in the same patients a diet with from 12.22 to 15.33 mg. (calculated) of iron produced a positive balance. The authors interpret the results as suggesting that from 12 to 15 mg. of iron per day should be considered the minimum for adequate intake.

**Hemoglobin values in Pennsylvania mass studies in human nutrition,** P. B. MACK, J. M. SMITH, C. H. LOGAN, A. T. O'BRIEN, J. J. SHAW, and P. DODDS. (Pa. Expt. Sta. and State Col. et al.). (*Milbank Mem. Fund Quart.*, 19 (1941), No. 3, pp. 282-303, figs. 8).—Hemoglobin values obtained for 2,400 subjects in a mass study in human nutrition carried on in Pennsylvania from 1935 until 1940 with rural and urban families and school children in four typical communities revealed a distribution of hemoglobin values from less than 7.5 gm. to more than 13.0 gm. per 100 cc. of blood. There was no significant difference between hemoglobin values for boys and girls below 12 yr. of age, although beyond this age males were found to be significantly higher than females. Below 6 yr. of age the values were definitely lower than for other age groups. Both sexes showed marked increases during the ages when puberty is most likely to occur, after which values decreased sharply and remained at a constant average for age groups from 20 to 40 yr. and 40 yr. and older. The rural subjects were found to be more nearly uniform in value than urban, children of preschool age in the urban families were much lower than children of the same age among rural families, children in an economically depressed industrial community were exceptionally low in hemoglobin values as compared with those in other communities in better economic condition, and scattered cases of all sex and age groups in all parts of the State were far below the average for the group. These latter generalizations are interpreted to indicate that individual cases of poor nutritional status may be detected through low hemoglobin values even if the optimum status with respect to this value has not been ascertained for various ages of the two sexes.

**Quantitative studies in the development of the rat molar.**—I, The growth pattern of the primary and secondary dentin (from birth to 500 days of

age), M. M. HOFFMAN and I. SCHOUR. (Univ. Ill.). (*Anat. Rec.*, 78 (1940), No. 2, pp. 233-251, pl. 1, figs. 4).—The rate of apposition of primary and secondary dentin was studied in 63 albino rats from 1 to 502 days old. The animals were given multiple injections of 2 percent alizarin red S, the doses averaging 100 mg. per kilogram of body weight, and were sacrificed at different ages, for the preparation of ground sections of the molars. These sections showed a red line in the dentin which was calcifying at the time of each injection. Microscopic study of the sections with micrometer measurements between successive red lines in the primary and secondary dentin along the dentinal tubules indicated that the apposition of primary dentin starts at birth and continues up to about 135 days of age, with a daily rate of apposition ranging from approximately  $16\mu$  to  $1\mu$ . After 80 days growth ceases along the long axis of the pulpal surface and is confined to the roof and floor of the pulp chamber. The incremental pattern of the primary dentin is conical, with the apex toward the cuspal growth center. Rate of dentin growth is independent of body weight. In the secondary dentin apposition begins at 35-40 days of age concomitant with the clinical occlusion and continues as late as 500 days of age. In the pulpal horn the apposition shows a rate varying from  $16\mu$  to  $1.3\mu$ , with a conical incremental pattern having the apex toward the pulp. It is concluded that dentin growth is not uniform but proceeds along definite gradients, and that the primary dentin of the rat molar can be used as an indicator of experimental conditions in animals up to 100 days of age, vital staining with alizarin red S permitting quantitative study of the entire growth pattern.

The stimulatory effect of calcium upon the succinoxidase activity of fresh rat tissues, A. E. AXELROD, K. F. SWINGLE, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 140 (1941), No. 3, pp. 931-932).—The succinoxidase activity of rat liver, as measured by oxygen uptake in the presence of succinate, was found to be stimulated by the addition of Ca ( $20\gamma$  as  $\text{CaCl}_2$  per 40 mg. of liver furnishing from  $4\gamma$  to  $8\gamma$  of Ca), the increase amounting to from 43 to 80 percent with minced liver and to 93 percent with homogenized liver. The addition of cytochrome c ( $3 \times 10^{-8}$  mole per flask) decreased the magnitude of the stimulatory effect to 48 percent. Succinoxidase activity of homogenized kidney cortex (20 mg. per flask) was stimulated 40 percent in the presence of the added Ca and was not affected by cytochrome c. The most pronounced effect of Ca was observed in the case of homogenized heart tissue (20 mg. per flask) in which the addition of  $20\gamma$  of Ca in the presence of  $3 \times 10^{-8}$  mole of cytochrome c caused an increase of 200 percent in succinoxidase activity.

The influence of fat on calcium and phosphorus metabolism, J. H. JONES (*Jour. Nutr.*, 20 (1940), No. 4, pp. 367-376).—The synthetic rachitogenic diets fed to young rats in the present study were similar to those previously described (E. S. R., 81, p. 879). Diet 570, containing 1.1 percent of calcium and 0.09 percent of phosphorus, was modified by the addition of lard or other substances at the expense of the carbohydrate, the substitution being on a weight basis in some cases and on a calorie basis in others. Calcification, as judged by bone ash, line test, and serum calcium and phosphorus values, was definitely increased by lard at levels varying from 5 to 25 percent on either the weight or the calorie basis. This increased calcification was not associated with the nonsaponifiable portion, as shown by other trials in which this material in amounts equivalent to 50 percent of the original fat was used in place of the lard. With a slight change in salt mixture so that the calcium content of the diet was but moderate (0.38 percent), the lard still effected increased calcification. Upon reduction of the phosphorus to very low levels (0.02 percent), the effect of the lard was less pronounced than on diets higher in phosphorus. Uncombined oleic acid was

almost as effective as lard in antirachitic activity, but sodium oleate and the calcium soaps of lard failed to be effective. These results are interpreted to disprove the theory that fats act by forming calcium soaps, thereby increasing the absorption of this element. Other theories advanced to explain the action of fats in favorably influencing calcium and phosphorus utilization are discussed in the light of the present findings. The data are considered to disprove the several theories except for the one explaining the action of the fat on the basis that it increases the acidity of the intestinal tract, and thus admits of subsequent greater absorption of calcium and phosphorus.

**The effect of dietary calcium and phosphorus on the assimilation of dietary fluorine**, M. LAWRENZ and H. H. MITCHELL (Ill. Expt. Sta.). (*Jour. Nutr.*, 22 (1941), No. 1, pp. 91-101).—The effect of varying levels of dietary calcium and phosphorus on the deposition of dietary fluorine (9, 12, and 32 p. p. m.) in soft tissues, skeleton, and teeth was determined in experiments with growing rats receiving equalized portions of comparable rations and sacrificed for analysis after consuming definite quantities of ration. Comparison of analyses of these rats with those of control animals analyzed at the beginning of the experiment permitted estimation of fluorine retention. The results indicated that an increase in dietary calcium from 0.23 to 0.73 percent, phosphorus remaining constant, produced heavier dry fat-free skeletons with higher percentages of ash, calcium, and phosphorus, but depressed the total retention of fluorine by from 10 to 13 percent, this effect being more noticeable in teeth and soft tissues than in bones. An increase in dietary phosphorus from 0.14 to 0.71 percent, dietary calcium remaining constant, produced a heavier dry fat-free skeleton, but did not modify appreciably the total retention of fluorine or the distribution of retained fluorine among bones, teeth, and soft tissue.

"Presumably dietary calcium consumed in concentrations above certain minimum (inadequate?) levels, protects the body against dietary fluorine, in food or in water, by impairing its assimilation to some extent, especially in those tissues, the teeth and the soft tissues, where its most deleterious effects would be exerted."

**Chronic endemic dental fluorosis (mottled enamel)**, M. D. CLAWSON, E. S. KHALFAH, and A. J. PEEKS (*Jour. Amer. Dent. Assoc.*, 27 (1940), No. 10, pp. 1569-1575).—By way of review, the lesion of mottled enamel is described and classified into six recognized types according to degree of severity; a brief historical survey is presented of the studies leading to the establishment of the etiologic factor in the mottling of human enamel; preventive measures are discussed; and several measures suggested for removing (not curing) the unsightly mottling of endemic fluorosis are outlined.

Areas of endemic fluorosis not previously mentioned in the literature are reported from western Asia. The current report deals with investigations of the water supply for fluorine content and with the dental conditions of the present inhabitants of the ancient city of Palmyra. It is believed that enough proof is available from water analyses and observations "to declare the whole of the Arabian Peninsula, Asia Minor, the Near East, and Mesopotamia endemic, in scattered sections at least, to this water-borne mottling of human teeth." Specifically, "three areas were positively identified in Iraq, two in Trans-Jordan, two in Syria, one in Bahrein Islands, two in Trucial Oman, Arabia, and one in Palestine."

**Further observations on the influence of dietary protein on the toxicity of selenium**, M. I. SMITH and E. F. STOHLMAN (*Jour. Pharmacol. and Expt. Ther.*, 70 (1940), No. 3, pp. 270-278, figs. 2).—Lactalbumin, ovalbumin, gelatin, and the proteins of wheat, dried brewers' yeast, and desiccated pork liver,

supplied at a 20 percent level, replacing the starch of the basal diet which carried 10 p. p. m. of naturally occurring wheat selenium (from 50 percent of seleniferous wheat) and 10 percent of protein, afforded protection against the toxic effect of this selenium. Not only did these protein supplements admit of normal growth of the rats, as judged by comparison with control animals receiving similar diets containing nonseleniferous wheat, but they offered protection against all the toxic manifestations of selenium poisoning, such as effusions, anemia, and liver injury. This protective action of dietary protein against the chronic toxicity of ingested selenium confirms the results previously observed (E. S. R., 83, p. 141) with casein. *d*-Lysine (1.7 percent) and *d*-methionine (0.8 percent) were without effect, and glucosamine (2 percent) afforded only partial protection. "Experiments with graded increments of the protein casein showed that the degree of protection against 15 p. p. m. inorganic selenium fed as sodium selenite is related to the quantity of protein in the diet. Cystine and methionine in amounts sufficient to support normal growth in rats on a diet containing only 4 percent casein failed to mitigate the toxic effects of the selenium."

**Wall chart: A guide to vitamins and minerals in the family meals, J. E. RICHARDSON and J. T. CHASE** (*Montana Sta. Cir. 165 (1941), pp. 4*).—This convenient chart lists the amounts of vitamins and minerals recommended by the committee on food and nutrition, National Research Council, May 1941, as the daily allowance per person, and lists amounts of each of these (vitamins A, B, C, riboflavin, Ca, P, and Fe) to be found in serving portions of common foods. A sample menu based on these foods includes all daily allowances.

**The vitamin content of meat, H. A. WAISMAN and C. A. ELVERJEM** (*Minneapolis, Minn.: Burgess Pub. Co., 1941, pp. [I]+II+210*).—This book, in processed form, summarizing available information on the nutritive value of meat and meat products, is based on data assembled from the literature and on analyses and assays made in the authors' laboratory. It is pointed out that the values presented are not final and must be considered as subject to such revision as future work may dictate. Individual chapters are devoted to the more important nutrients, vitamins A, D, E, K, and C, thiamin, riboflavin, nicotinic acid, pyridoxin, pantothenic acid, additional factors newly recognized as vitamins, and proximate constituents. Sufficient information is supplied in each case so that the value of meat in meeting the requirements for these nutrients can be considered in the light of the most recent developments. Specifically, the physiology, pathology, and therapeutics of the vitamins are discussed, and, where available, information is given on the influence of cooking on the vitamin content of meat. Currently acceptable assay methods, including biological, microbiological, and chemical technics are discussed briefly, and the procedure used in the authors' laboratory for preparation of the samples is described. A summary chapter gives general values for the vitamin content of the most important forms of meat products.

**Retention of vitamins by dried fruits and vegetables, E. M. MRAK** (Univ. Calif.). (*Fruit Prod. Jour. and Amer. Vinegar Indus., 21 (1941), No. 1, pp. 13-15*).—Presented as an address, this brief survey indicates that (1) steam blanching tends to preserve vitamins A, B<sub>1</sub>, and C in dehydrated vegetables; (2) sulfuring preserves A and C, has no effect on riboflavin, and tends to destroy B<sub>1</sub> in dried fruits; (3) dehydration is superior to sun-drying from the standpoint of vitamin retention; (4) alkaline dips have no destructive effect on vitamins A, B<sub>1</sub>, and riboflavin; and (5) loss of vitamins A and C by dried fruits increases as SO<sub>2</sub> content decreases, the destruction of vitamin A and probably vitamin C being rapid in fruits containing less than 400 p. p. m.

of  $\text{SO}_2$ , and the loss of  $\text{SO}_2$  being more rapid from fruit containing from 18 to 20 percent moisture than from that containing from 12 to 14 percent.

**Changes in dietary value during food preservation, W. V. CRUESS.** (Univ. Calif.). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 21 (1941), No. 2, pp. 40-42).—An address summarizing briefly the changes in mineral constituents, vitamins A, B<sub>1</sub>, and C, and riboflavin, generally occurring in the processes of blanching, sterilizing, freezing storage, sun-drying, and fermentation (alcoholic and lactic).

**What vitamins mean to the quick frozen food industry, H. H. FLAGGE.** (Iowa Expt. Sta.). (*Quick Frozen Foods*, 3 (1941), No. 9, pp. 24, 39-40).—An address.

**The question of the synthesis of vitamin A from carotene in the rat** [trans. title], H.-J. BIRLG (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 266 (1940), No. 1-3, pp. 112-116, fig. 1).—No difference was observed in the onset of xerophthalmia in similar groups of rats kept on a vitamin A-free diet in the dark and under continuous irradiation with a daylight lamp, or in the cure of xerophthalmia and resumption of growth following the administration of  $\beta$ -carotene to both groups. This is considered to indicate that the synthesis of vitamin A from carotene in the body of the rat does not depend upon the action of light on epithelial pigment.

**Effect of reduced evaporation on the provitamin A content of lettuce in refrigerated storage, R. S. HARRIS and L. M. MOSHER** (*Food Res.*, 6 (1941), No. 4, pp. 387-393, fig. 1).—Throughout this study the lettuce used was obtained at the same stage of maturity from the same greenhouse, and the sound washed leaves were sorted at random into five lots, one of which was used as fresh lettuce, while the other four were used after 7 days' storage in which they were held, respectively, in the open compartment or the vegetable hydrator of two refrigerators identical in type with those used in a previous study (*E. S. R.*, 85, p. 706). Average temperature and relative humidity in the open compartments were 40.7° F and 69.1 percent and 41.6° and 88.0 percent in the two refrigerators, respectively, with the corresponding hydrators at 45.6° and 96.1 percent and 41.2° and 98.3 percent. Air movement in the four cases averaged about 10 ft. per minute, 2 ft. per minute, very low, and virtually nil.

The loss of provitamin A in the lettuce was determined by bio-assay procedure (U. S. P. XI, second supplement) in which the lots of stored lettuce were fed to groups of 50 avitaminotic rats at levels sufficient to produce growth equal to that obtained in a similar group of animals fed the fresh lettuce. The relative provitamin A potencies of the four lots of stored lettuce as compared with that of the unstored lettuce taken as 100 were 69, 82, 92, and 95, respectively. These figures indicated greater retention upon storage in the hydrators where relative humidities were higher and air movement lower than in the open compartments, and in the open compartments greater retention in the refrigerator kept at the higher humidity. The extent of provitamin A destruction did not correlate with the difference in temperature during storage as well as with the percentage loss of moisture. The rate of destruction during dehydration appeared to be linear until about 40 percent of the weight was lost, then the destruction appeared to be accelerated. The lettuce became wilted by the time it lost 30 percent of its weight, and wilting, therefore, could be used as an index of loss in initial provitamin A content. Since moisture loss is a function of relative humidity and air movement, it appears that high humidity and low air movement are important in the preservation of the vitamin content of vegetables stored in the refrigerator.

**Relationship of vitamin A blood level in the rat to vitamin A intake and to liver storage,** J. M. LEWIS, O. BODANSKY, K. G. FALK, and G. MCGUIRE (*Soc. Eept. Biol. and Med. Proc.*, 46 (1941), No. 2, pp. 248-250).—When the vitamin A intake of rats was less than 50 International Units daily, the concentration in the blood was directly related to the consumption. Above 50 I. U., the daily intake had no effect on the amount of vitamin A in the blood, but the storage in the liver continued to increase. There were 100 I. U. per 100 cc. of blood with an intake of 50 I. U., and only 110 I. U. when 1,000 I. U. per day were consumed. Under these conditions the vitamin A storage in the liver increased from 228 to 10,000 I. U. per liver. There was no liver storage with less than 37 I. U., and little up to 53 I. U. per 100 cc. of plasma.

**Dark adaptation and experimental human vitamin A deficiency,** S. HECHT and J. MANDELBAUM (*Amer. Jour. Physiol.*, 130 (1940), No. 4, pp. 651-664, figs. 3).—Because of differences reported in the literature concerning the time when a rise of the visual threshold first appears in dark-adaptation tests during the period of a vitamin A-deficient diet, the effect of single large doses of vitamin A following a deficient diet, and the rate of recovery of the visual threshold on return to a normal diet, the authors have made a detailed study of these points on 17 male subjects between 21 and 30 yr. of age. The procedure for the dark adaptation test with the Hecht apparatus "involves light adaptation to 1,500 millilamberts of 3 min., and measurements during the subsequent darkness of the threshold of a retinal area 3° in diameter situated 7° nasally for flashes of violet light 0.2 sec. in duration."

All but 3 of the subjects responded almost immediately to the A deficiency by a rise in visual threshold, which continued throughout the period on the deficient diet. The others required 22, 53, and 60 days, respectively, before a definite and continuous rise in threshold occurred. None of the subjects showed any skin changes and only 2 recorded symptoms of night blindness. The presence or absence of other vitamins in the diet had no effect on the visual threshold. Among 9 subjects tested with single doses of vitamin A, variable results were obtained. In no case was the recovery complete and in all the effects were only temporary. With resumption of a normal diet or with continued supplementation of the basal diet with vitamin A, permanent recovery was variable but slow. In one subject 6 weeks were required for return to normal. At the other extreme was a subject who showed but little improvement in over 3 mo., but recovered completely in a year.

**A note on the distribution of vitamin B<sub>1</sub> (thiamin) in the rice grain** (*Malayan Agr. Jour.*, 29 (1941), No. 3, pp. 127-128).—By chemical methods for detecting thiamin it was indicated that about 50 percent of the thiamin content of the rice grain was concentrated in the embryo.

**The functions of diphosphothiamine (phosphorylated vitamin B<sub>1</sub>),** E. S. G. BARRON and C. M. LYMAN (*Science*, 92 (1940), No. 2389, pp. 337-338) — A brief report is given of in vitro experiments with rat kidney and liver slices, demonstrating that "the synthesis of carbohydrates and of citric acid with pyruvate as one of the substrates is diminished in tissues from avitaminotic rats and is increased on addition of vitamin B<sub>1</sub>. They are offered as evidence for our view that vitamin B<sub>1</sub> is a catalyst not only for oxidation and decarboxylation of pyruvate, but also for many other reactions where pyruvate is one of the reacting substances."

**Vitamin B<sub>1</sub> in the urine after the administration of larger doses** [trans. title], I. MAGYAR (*Klin. Wchnschr.*, 20 (1941), No. 17, p. 425).—The author suggests the possibility of a more effective utilization of vitamin B<sub>1</sub> when massive doses are prescribed if the dosage is distributed through the day rather than given at one time. In support of this suggestion, data are given showing ex-

tremely large amounts of the vitamin excreted by patients with various diseases when treated with vitamin B<sub>1</sub> in single daily doses of 100 mg. and the much lower excretion of the vitamin by two healthy subjects during a 12-hr. period following four doses at 3-hr. intervals of 10 mg. of the vitamin as compared with a single dose of 40 mg.

**Clinical experiences with the measurement of the urinary excretion of vitamin B<sub>1</sub>.** G. A. CARDIN, W. D. PROVINCE, and J. W. FERREBEE (*Soc. Expt. Biol. and Med. Proc.*, 45 (1940), No. 1, pp. 1-5).—Using a modification of the Hennessy and Cerecedo thiochrome method (*E. S. R.*, 82, p. 588), the authors measured the 24-hr. urinary excretion of vitamin B<sub>1</sub> of a small group of normal subjects (interns) on their usual diets and of a similar group of hospital patients suspected of vitamin B<sub>1</sub> deficiency. The response of the normal group to a 0.5-mg. test dose injected subcutaneously and of a number of the patients following vitamin B<sub>1</sub> treatment in various dosages was also determined.

The normal subjects excreted from 108 to 390  $\mu$ g. of vitamin B<sub>1</sub>, with an increase of from 10 to 40 percent of the added dose in the tolerance test. The 24-hr. excretion of the patients suspected of vitamin B<sub>1</sub> deficiency ranged from 5 to 70  $\mu$ g., and approximately normal increases following the test dose were for the most part obtained only after several doses. Although it is recognized that further work is necessary before accurate interpretation of B<sub>1</sub> tolerance tests can be attempted, the evidence is considered conclusive that subjects who have been on low vitamin B<sub>1</sub> diets excrete less than the usual amount of vitamin B<sub>1</sub> in the urine, and the more deficient subjects show a lessened excretion of B<sub>1</sub> following the administration of small doses of the vitamin. It is thought of interest that in a year no patient was found whose excretion of vitamin B<sub>1</sub> could not be raised to normal by the administration of quantities of vitamin B<sub>1</sub> comparable to those obtainable in ordinary diets.

**Effect of processing on the vitamin B<sub>1</sub> content of foods,** R. S. HARRIS, B. E. PROCTOR, S. GOLDBLITH, and J. BRODY (*Inst. Food Technol. Proc.*, 1 (1940), pp. 109-121).—The summary, based on comparatively recent findings reported in the literature, points to the losses of thiamin entailed in the production of refined cereals and cereal products; in the pasteurization of milk and production of evaporated and condensed milks, and to the slight destruction in the manufacture of dried milks; to the variable destruction of the vitamin in cooking and its loss through the discard of cooking waters; and to the slight effect of rapid dehydration, freezing, and ordinary storage on the thiamin content of foods. Original data on canning losses are presented. To obtain information on this matter, tests were conducted on 25 samples of vegetables and fruits which were prepared and packed in a manner similar to commercial procedures and processed in an experimental canning laboratory. Samples of the fresh foods taken at the time of canning were assayed by a fluorometric procedure, and the assays were repeated on samples taken immediately after canning and again after 50 days. The thiamin determination was made by a modification of the Hennessy and Cerecedo method (*E. S. R.*, 82, p. 588). The modifications consisted of "digestion of the macerated tissue by 3 percent, rather than 2 percent, acetic acid; concentration of the food thiamin by passage through 80 mesh, rather than 30 mesh, exchange zeolite; and elimination of sodium sulfate as a dehydrating agent. Furthermore, the fluorophotometer was standardized directly against synthetic thiamin chloride and not against quinine sulfate." The method was found to give results agreeing within 10 percent of those obtained by bio-assay. The recorded losses in the experimental canning of fruits and vegetables varied from 0 in orange juice to as high as 88 percent in grapefruit segments. It is pointed out that the extent of destruction in the various

foods was similar to that noted by others in the cooking of the same types of foods by cooking procedures. From 24 to 51 percent of the thiamin of the vegetables canned was found in the juice after canning.

**A report on loss of vitamin B<sub>1</sub> in baking**, C. G. HARREL, R. C. SHERWOOD, B. SULLIVAN, and W. L. RAINEX (*Southwest. Miller*, 20 (1941), No. 24, pp. 19, 31).—This paper presents the findings by a subcommittee of the technical committee of the Millers' National Federation on vitamin B<sub>1</sub> loss in baking. The work, done by four collaborators, consisted in determining by the thiochrome method the vitamin B<sub>1</sub> content of crust, crumb, and whole loaf of 1-lb. loaves of thiamin-enriched bread baked in a commercial rotary oven equipped with steam or in a laboratory forced-draft oven. The flours used were enriched with synthetic thiamin or with thiamin-rich yeast. Doughs at the molding stage from the corresponding bakes were also analyzed. The samples of breads and doughs were air-dried before distribution for analysis under code numbers.

The limits of vitamin B<sub>1</sub> losses in baking were found to vary from 6.8 to 29.1 percent between the two extremes of baking conditions. Little difference between the two forms of enrichment was apparent, and practically all the loss of vitamin B<sub>1</sub> occurred in the crust. In the crumb the average loss was 4.6 percent. The loss of vitamin B<sub>1</sub> increased greatly with increased baking time (at constant temperature) and with increased temperature of baking (time remaining constant). Under medium conditions (30 min. at 425° F.), which gave a very well-baked commercial loaf, the vitamin B<sub>1</sub> loss was approximately 16 percent, while with a somewhat lighter bake (20 min.) the loss averaged approximately 10 percent. It is pointed out that time, temperature, oven load, type of bake, size and shape of pan, type of oven, and pH of dough are all factors affecting vitamin B<sub>1</sub> losses, and that the average losses obtained in this study can be considered at best as only approximating the loss for any particular baking condition.

This collaborative study showed further the desirability of tested standards for the analytical work and the need for great precautions to insure complete extraction of the vitamin B<sub>1</sub> from the bread samples.

**Vitamin B<sub>1</sub> loss in baking**, C. G. HARREL, R. C. SHERWOOD, B. SULLIVAN, and W. L. RAINEX (*Bakers Digest*, 16 (1941), No. 3, pp. 42-45).—Essentially noted above.

**Physiological activity and experimental clinical use of vitamin B<sub>6</sub> (pyridoxine)** (Rahway, N. J.: Merck & Co., 1941, pp. [2]+35).—This review, under date of August 1941, is presented under the headings chemical and physical properties, history, occurrence, physiological activity (in rat, dog, and chick, and miscellaneous effects), clinical uses, dosage and methods of administration, toxicity, and methods of assay. A bibliography of 94 titles is appended.

**Toxicity of pantothenic acid**, K. UNNA and J. GREGLIN (*Soc. Exptl. Biol. and Med. Proc.*, 45 (1940), No. 1, pp. 311-312).—In continuation of the studies on the toxicity of the various vitamins of the B complex (E. S. IL, 84, p. 563), preliminary findings are reported demonstrating that "calcium pantothenate is, like other members of the vitamin B complex, a substance of extremely low toxicity. Excessively large doses (0.8 gm. to 10 gm. per kilogram, depending on the mode of administration) were found to produce death due to respiratory failure in mice and rats. Prolonged feeding of sublethal doses failed to produce toxic manifestations, indicating that an excess of pantothenic acid is either rapidly destroyed or excreted."

**Riboflavin deficiency among Chinese**, I, II, H. C. HOU (*Chin. Med. Jour.*, 58 (1940), No. 6, pp. 616-628, pls. 2; 59 (1941), No. 4, pp. 314-325, pls. 2).—This paper is presented in two parts as follows:

I. *Ocular manifestations*.—From an out-patient eye clinic in a Shanghai, China, hospital which examines about 150 new patients monthly, 36 cases were selected over a period of 3 mo. for observation and treatment of eye lesions suggestive of riboflavin deficiency. Four out of 9 pellagrins admitted to the hospital during the same period were similarly treated after cure of the pellagra by nicotinic acid as a supplement to a pellagra-producing diet.

The ocular lesions in order of decreasing frequency among the 36 nonpellagrins were pericorneal injection, bulbar conjunctivitis, photophobia, vascularization of the cornea, blurring of vision, phlyctenules in the conjunctiva or cornea (a sign of ariboflavinosis not pointed out before), corneal opacity, corneal ulcer, blepharitis, and iritis. Riboflavin was administered usually by mouth, starting with 15 mg. in three separate doses for the first day or two, then 10 mg. daily for from 3 to 10 days, depending upon the severity of the disease, and finally 5 mg. daily for another week. Within 24 hr. definite relief from photophobia was experienced, followed within 48 hr. by improvement in bulbar conjunctivitis, phlyctenules, corneal vascularization, and pericorneal congestion. In 4 or 5 days healing was practically complete, with the exception of corneal ulcers which healed more slowly and usually left a trace of corneal opacity. Cheilosis and glossitis, observed in only 5 of the cases, were cured within from 4 to 7 days and seborrheic lesions in from 10 days to 2 weeks. The effect of carotene in massive doses was tested in a few cases before initiating riboflavin treatment or as a substitute for riboflavin during treatment but with no success.

The eye lesions in the pellagrins, which consisted only of pericorneal injection and bulbar conjunctivitis in a mild degree, showed no change under nicotinic acid therapy but responded rapidly to riboflavin and more slowly to yeast. Three case reports are given in detail, and photographs are included illustrating the various types of ocular lesions.

II. *Cheilosis and seborrheic dermatitis*.—Ten children selected from a refugee camp where a large number had cheilosis, chiefly of the milder type, and 10 pellagrins showing cheilosis and/or seborrheic disease were treated for riboflavin deficiency as in part I and with equally good results. It is considered of interest that cheilosis and ocular lesions, although responding to the same treatment, seldom occurred together, but that cheilosis was quite common among the pellagrins. It is suggested that the ocular manifestations may represent a pure riboflavin deficiency and cheilosis a riboflavin deficiency, with possibly a very mild degree of nicotinic acid deficiency.

A new factor of the vitamin B complex required by the albino mouse, E. R. NORRIS and J. HAUSCHILD (*Science*, 92 (1940), No. 2388, pp. 316-317).—In a study of the requirements of the albino mouse for the various factors of the vitamin B complex skin lesions, as well as failure to grow, were observed on a basal vitamin B complex-free diet supplemented with pyridoxin, thiamin, nicotinic acid, and riboflavin, with the addition of a filtrate from a fuller's earth adsorption of either yeast or liver. The skin lesions are said to be similar to those described by György and Eckhardt (*E. S. R.*, 83, p. 713), but to differ in certain respects from them and other skin lesions described in the literature. "The paws, ears, nose, and tail, and in most cases the eyes appear normal. In a few cases a sticky exudate is observed about the eyes. The lesions are preceded by loss of hair on the abdomen, closely followed by the appearance of shiny skin in the inguinal region. This in turn is soon followed by a scaly dandruff-like appearance beginning almost simultaneously on the back of the neck and in the inguinal region. If the animal survives this stage of the deficiency, the pelt frequently begins to come off in large plaques, particularly on the back, leaving a dry but otherwise normal-appearing hairless skin. . . . In some cases, the

peeling off of the pelt does not occur, but instead the dandruff-like appearance spreads over the body and the hair gradually falls out, leaving the animals covered with dry white scales."

**Ascorbic acid content of pigmented fruits, vegetables, and their juices,** M. M. KIRK and D. K. TRESSLER. (N. Y. State Expt. Sta.). (*Food Res.*, 6 (1941), No. 4, pp. 395-411).—This paper presents in detail the findings summarized in an earlier report (E. S. R., 85, p. 134).

Fruits showed daily variation in ascorbic acid content, associated probably with differences in part of the season, ripeness, amount of sun, and quantity of rain. There were also decided varietal differences and differences depending upon the part of the fruit analyzed. Thus, peach skins contained from two to four times as much ascorbic acid per gram as the pulp, and eggplant skins were richer in this vitamin than the rest of the fruit, with little difference between the portion immediately under the skin and the center portion. The ascorbic acid content of 11 varieties of strawberries varied from 0.40 to 1.04 mg. per gram, of 7 varieties of raspberries from 0.13 to 0.30, of 6 varieties of blueberries from 0.12 to 0.20, of 5 varieties of plums from 0.03 to 0.10, of 2 varieties of cherries from 0 to 0.09, of 11 varieties of peaches from 0.06 to 0.14 (in the pulp), and of 5 varieties of turnips from 0.32 to 0.48 mg. per gram. Eggplant of the Black Beauty variety, averaging for the entire fruit 0.05 mg. of ascorbic acid per gram, showed but small losses in storage. Much vitamin C of fruits was lost in preparing them for juicing, but such loss was inhibited by heating (between 140° and 170° F.). The pressing process caused some loss of ascorbic acid, and the addition of sugar to the fruit juice caused further loss, apparently due to oxidation by air incorporated in stirring in the sugar. Apple juice as commonly prepared was very low in ascorbic acid (from 0.01 to 0.02 mg. per gram). With Greening and Cortland varieties much of the ascorbic acid was retained in the pomace after pressing out the juice, but this was not true of Baldwin apples.

**Changes in vitamin C content of Bartlett pears in cold and gas storage,** D. K. TRESSLER and J. C. MOYER. (N. Y. State Expt. Sta. et al.). (*Food Res.*, 6 (1941), No. 4, pp. 373-376).—Fruits grown in a commercial orchard in the Niagara peninsula in Ontario were harvested when their ground color was beginning to turn from green to yellow and placed in cold storage at 30° F., half of them being held in large open cans and half in smaller sealed cans having either a  $\frac{5}{64}$ - or a  $\frac{7}{64}$ -in. (diameter) hole in the lid. Fruits analyzed when freshly picked showed an ascorbic acid content of 0.090 mg. per gram (0.82 mg. per gram, dry-weight basis). Those held in open storage lost vitamin C rapidly, decreasing to 0.034 mg. per gram (0.42, dry basis) in the first month and to 0.049 mg. per gram (0.33, dry basis) after 2 mo., with little change thereafter. After 3 mo. the quality of these fruits began to decline. Fruits held in the closed cans where the atmosphere was found to contain 2-4 percent CO<sub>2</sub> and 17-19 percent O<sub>2</sub>, depending upon the size of the diffusion hole, lost ascorbic acid less rapidly than fruits held in open cans. The pears held in gas storage were sound in quality at the end of 7 mo., at which time they contained 0.051 and 0.036 of ascorbic acid per gram (0.36 and 0.26 mg., dry basis) when held in cans with the smaller and larger diffusion holes, respectively.

**Vitamin D content of dairy products—methods of fortifying milk,** K. G. WECKEL. (Univ. Wis.). (*Inst. Food Technol. Proc.*, 1 (1940), pp. 133-137).—This brief survey deals with the occurrence and stability of vitamin D in milk, with the variation in the amount naturally present, and with the several methods of increasing the vitamin D content of dairy products.

**Effect of renal damage on the toxicity of hypervitaminosis D in rats,** L. OPPER. (Ark. Expt. Sta. and Univ.). (*Arch. Pathol.*, 31 (1941), No. 5, pp. 569-577, figs. 4).—Forty rats on a diet furnishing an average daily intake of

vitamin D were made markedly deficient in vitamin A several times in the course of a 4- to 7-mo. period. At autopsy these animals showed extensive renal damage, and 37 of them showed extensive arterial calcification commensurate with the degree of renal damage. Controls receiving the same diet but not depleted in vitamin A showed no tissue calcification. In another group of 27 rats kidney insufficiency was produced by partial nephrectomy, and large doses of vitamin D as viosterol (13,000-29,000 units) were then administered daily over a period of from 6 to 19 days. At autopsy, tissue calcification was found to be very pronounced. Control rats (not operated on) received somewhat larger average daily supplements of vitamin D, yet their tissues revealed no calcification. Blood serum removed at autopsy from the nephrectomized animals and the controls not operated on averaged, respectively, 20.67 and 12.52 mg. of inorganic P and 13.77 and 13.36 mg. of Ca per 100 cc. These findings indicate that renal damage, whether produced by chronic vitamin A deficiency or by partial nephrectomy, may influence the toxicity of excessive vitamin D in the diet. The blood picture suggests that high serum P rather than high Ca is significant in the calcification of the soft tissues and that one of the causes of elevation in the inorganic P of the blood is renal insufficiency.

**Routes of administration of materials capable of acting as vitamin K,** E. J. DEBEER, L. DREKTAR, and B. FLUSSER (*Soc. Expt. Biol. and Med. Proc.*, 46 (1941), No. 4, pp. 535-537).—Studies of the blood clotting time in chicks when 2-methyl-1,4-naphthoquinone was administered orally, intramuscularly, and percutaneously in lieu of vitamin K showed that as little as 1γ per chick percutaneously reduced the clotting time of 11 of 24 chicks to 10 min. or less 24 hr. after dosing.

**The avitaminoses,** W. H. EDDY and G. DALLDORF (*Baltimore: Williams & Wilkins Co.*, 1941, 2. ed., pp. XIII+519, pls. 41. figs. 28).—A revision of the volume previously noted (E. S. R., 77, p. 891).

**A note on the interrelationship of deficiency diseases and resistance to infection,** J. W. RIDDLE, T. D. SPIES, and N. P. HUDSON. (Ohio State Univ. et al.). (*Soc. Expt. Biol. and Med. Proc.*, 45 (1940), No. 1, pp. 361-364).—In 150 selected cases of clinical pellagra, riboflavin deficiency, and beriberi with other associated deficiency diseases, the bacterial flora of the lesions associated with the various deficiencies was studied, complement titrations were made with venous blood, and the bactericidal power of the whole blood for *Staphylococcus aureus*, *Streptococcus viridans*, and *Neisseria intracellularis* was measured. A definite relationship was evident between the deficiency diseases and the resistance to and presence of infections with *Staphylococcus aureus* and *Streptococcus hemolyticus*. The lesions at the corners of the mouth characteristic of riboflavin deficiency contained pure or nearly pure cultures of hemolytic strains of *Staphylococcus aureus* in 80 percent of the cases, with *Streptococcus hemolyticus* predominating in the remaining 20 percent. The lesions healed rapidly and the organisms disappeared following oral or intravenous administration of riboflavin. Hemolytic strains of *Staphylococcus aureus* were isolated from the bacterial flora of the eyes in 14 of 30 cases of conjunctivitis. The presence of *Corynebacterium xerosis* was demonstrated in nearly all cases and in a pure state in Bilot's spots occurring in 5 of the patients. In 64 percent of ulcerations of the tongue, sinus, and buccal mucosa *Streptococcus hemolyticus* (in addition to masses of Vincent's organisms) was found and hemolytic strains of *Staphylococcus aureus* in the remaining 36 percent. Within 48 hr. following specific therapeutic treatment with substances rich in the vitamin B complex the ulcerated areas decreased in size and healed, and the organisms disappeared.

Acute deficiency was associated with low complement titer and subclinical and mild deficiency with slightly subnormal or normal titer. In the whole blood

of patients with acute deficiency there was a distinct depression in the bactericidal power for *S. aureus*, as compared with only a slight decrease in subclinical and mild cases of vitamin deficiency.

## TEXTILES AND CLOTHING

The Planoflex, a simple device for evaluating the pliability of fabrics, E. C. DREBY (*Jour. Res. Natl. Bur. Standards* [U. S.], 27 (1941), No. 5, pp. 469-477, pls. 2; also in *Amer. Dyestuff Rptr.*, 30 (1941), No. 24, pp. 651-654, 665-666, figs. 2).—The instrument, described and illustrated, serves to measure the angle to which the strip (3 by 10 in.) of fabric, held under a 2-lb. tension in a horizontal plane, may be shifted to the right or the left in its plane without producing longitudinal surface wrinkles. Results of measurements on 19 cotton percales showed an 88 percent correlation with tactual pliability ratings representing the average of judgment of eight textile men experienced in handling fabrics of this type; evaluation of pliability by the Schiefer Flexometer and the Peirce Hanging-Heart Loop methods gave correlations of 88 and 51 percent. The Planoflex was found to be well-adapted to testing a wide variety of woven fabrics, although it could not be used indiscriminately to evaluate the relative pliabilities of fabrics of different fiber construction. Heavily starched fabrics did not give measurable results on it, and knit fabrics were too easily distorted and stretched to give values of any significance. The instrument is recommended because of its simplicity of construction and operation, its direct readings, and the requirement of but few specimens to give a reproducible average value.

Role of cystine in the structure of the fibrous protein, wool, W. I. PATTERSON, W. B. GEIGER, L. R. MIZELL, and M. HARRIS (*Jour. Res. Natl. Bur. Standards* [U. S.], 27 (1941), No. 1, pp. 89-103, figs. 4).—The behavior of wool in a series of highly specific reactions was observed, the results suggesting that a number of its important physical and chemical properties are associated with the presence of disulfide cross-linkages between polypeptide chains of the protein. Whereas strongly alkaline solutions of thioglycolic acid dissolve the protein of wool and destroy the fibrous structure, neutral or acid solutions of the reagent can reduce wool over a wide range of pH without destroying the fibrous structure. Such reduced wool can easily be oxidized. In the reduction the disulfide cross-linkages between the polypeptide chains of the protein are reduced to sulfhydryl groups which are capable of reacting readily with the alkyl halides to form thioether groups. Reaction with alkyl monohalides, such as methyl iodide, apparently causes permanent rupture of the disulfide linkages, since the resulting fibers are greatly increased in extensibility and reduced in strength. These, as well as the reduced fibers, are much more soluble in alkali than untreated wool. Alkylation of the reduced wool with alkyl dihalides, such as methylene iodide, introduces hydrocarbon chains between pairs of cystine molecules in the fibers. The resulting fibers are very similar to the untreated ones in physical properties but possess much lower alkali solubility. It is suggested that this latter reaction, wherein relatively unstable disulfide cross-linkages are converted to extremely stable thioether cross-linkages, may be useful in overcoming the susceptibility of wool to degradation by alkali.

Microscopic structure of the wool fiber, C. W. HOCK, R. C. RAMSAY, and M. HARRIS (*Jour. Res. Natl. Bur. Standards* [U. S.], 27 (1941), No. 2, pp. 181-190, figs. 16; also in *Amer. Dyestuff Rptr.*, 30 (1941), No. 18, pp. 449-456, 469-470, figs. 16).—Whereas untreated wool was not readily attacked by pepsin, wool that had been reduced with thioglycolic acid and then methylated was

attacked by the enzyme even at room temperature so that after several days the fibers lost their luster and became striated, due to increased prominence of the cortical cells. After long treatment large numbers of these cells were liberated from the fiber. Placed in fresh enzyme for a month, some of the liberated cells appeared to be digested while others remained intact, the differences being apparently associated with the extent of reduction of the wool and suggesting that the undigested cells were the ones in which the disulfide cross-linkages were intact. Microdissection of liberated cortical cells showed their striated appearance to be due to the presence of many fibrils which could be separated with micro-needles. Near the center of each cell there was a granular nucleus. Between crossed nicols the fibrillar part appeared birefringent, whereas the nucleus did not.

The scale cells were not appreciably attacked by the pepsin, but remained attached in the form of tubes, with the scales overlapping, as the cortical cells were digested. Under the microscope the scale cells showed no fibrillar structure; between crossed nicols they appeared nonbirefringent. The root and the shaft showed numerous differences in cellular structure and microchemical color tests. These and other observations indicated that as the cells of the root emerge into the shaft physical and chemical changes take place simultaneously. The Allwörden reaction, involving the formation of sacs upon the surface of a wool fiber immersed in chlorine water, appeared upon microscopic examination to be associated with sac formation on the scales of the shaft. Scales loosened from the fiber by treatment with concentrated sulfuric acid or formic acid showed that the swelling occurred between the upper and lower surfaces of individual scales. Response to certain chemical treatments suggested that the formation of sacs was associated with the reaction of the chlorine with the disulfide groups of the cystine in the scales. Numerous photomicrographs are given.

**Nature of the resistance of wool to digestion by enzymes, W. B. GEIGER, W. I. PATTERSON, L. R. MIZELL and M. HARRIS** (*Jour. Res. Natl. Bur. Standards* [U. S.], 27 (1941), No. 5, pp. 459-468, pls. 3; also in *Amer. Dyestuff Rptr.*, 30 (1941), No. 24, pp. 659-664, figs. 3).—Wool fibers that have not been injured mechanically or modified chemically were not attacked by solutions of crystalline pepsin, trypsin, chymotrypsin, or papain, as judged by the fact that the load required to stretch the relaxed fiber (immersed in water or neutral buffer) until elongated 30 percent was the same after treatment with the enzyme as it was before. When the cuticle or scale layer of the fibers was damaged by mechanical means the fibers became susceptible to attack by pepsin and chymotrypsin, which liberated cortical and scale cells but did not digest them; the microscopic appearance of the fibers suggested that an intercellular substance may have been digested. This enzyme action weakened the fibers so that they broke at 5- to 10-percent elongation.

Wool fibers in which the disulfide cross-linkages were broken by reduction with thioglycolic acid or by reduction and subsequent alkylation were rendered extremely susceptible to digestion with pepsin or chymotrypsin but were attacked only slightly by trypsin. The enzyme action consisted of digestion of the cortical material, liberation of some of the cortical cells, and formation of empty tubes of scales. Such fibers were so fragile that they broke into small pieces upon attempt to remove them from solution. When the reduced wool was reoxidized and its sulfhydryl groups were converted to disulfide groups, the wool regained its original stability. When the sulfhydryl groups of the reduced wool were converted to bis-thioether groups by the action of an aliphatic dihalide, the stability of the wool toward enzymes was greatly enhanced.

**Physical and chemical properties of flannels containing different proportions of new and reprocessed wool, B. BAILEY.** (S. Dak. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 63 (1941), No. 10, pp. 583-598).—Wool flannel fabrics containing different blends of new and reprocessed fiber were manufactured, using identical spinning, weaving, and finishing processes. Chemical and physical tests were applied to the fabrics as received from the manufacturer and after varying numbers of commercial dry cleanings and pressings.

"Comparisons of the fiber qualities of the new and reprocessed wool indicated that the new wool was finer, longer, and crimpier. No difference in average contour ratio was found. Ash and nitrogen were greater in the new fiber, whereas the sulfur content was lower. Examination of the fundamental properties of the four fabrics manufactured indicated that, when fibers of the nature described were used for blending, an increase in the percentage of reprocessed wool resulted in an appreciable decrease in the weight per square yard, though the number of yarns per inch decreased only slightly and the twist remained approximately the same. Comparisons between the diameter of the fibers in the finished fabrics and those in the new and reprocessed wool from which the fabrics were made indicated that the coarser reprocessed fiber must have been eliminated to a certain extent during manufacture. Determinations of the moisture, ash, nitrogen, and sulfur content of the fabrics before and after dry cleaning and pressing showed that the ash tended to increase with dry cleaning; that neither blend nor treatment affected the sulfur content appreciably; and that in all blends there was a marked increase in nitrogen between the fifteenth and thirtieth dry cleanings.

"Statistical methods were applied in the analyses of the effects of abrasion and dry cleaning and pressing on the four fabrics. Nonsignificant differences in strength between unabraded fabrics and fabrics abraded 1,000 times were found. However, there was a decrease in elongation following abrasion.

"When the interpretation of the results of the application of the analysis of variance was limited to comparisons between the four fabrics studied, it was found that the fabrics were significantly different in strength and elongation; the treatments to which they were subjected were significantly different; and in some instances they did not react similarly to treatment. Expanding the interpretation to indicate the general effects of blending new and reprocessed wool of the types used in this study in manufacturing flannel fabrics resulted in the conclusion that fabrics of different strength and elongation are produced, regardless of subsequent dry cleaning and pressing processes to which they may be exposed. Thus, regardless of the method of interpretation, it was found that increases in the percentage of the reprocessed wool used in this study resulted in corresponding decreases in fabric strength and elongation. The effects of dry cleaning and pressing were mixed and therefore inconclusive."

**Fabric properties of blends of new and reprocessed wool, B. BAILEY.** (S. Dak. Expt. Sta.). (*Textile Res.*, 11 (1941), No. 7, pp. 314-319, fig. 1).—Essentially noted above.

**The sulfuric acid and aluminum chloride carbonization methods for the determination of wool in mixed fabrics compared in an inter-laboratory study, L. E. WEIDENHAMMER, F. A. PRISLEY, and B. A. RYBERG.** (U. S. D. A. et al.). (*Amer. Dyestuff Rptr.*, 30 (1941), No. 14 pp. P348-P357).—This paper presents the findings of a collaborative study of these two methods applied in the analysis of six fabrics manufactured for experimental purposes and composed of all wool, wool and cotton, or wool and rayon blends. Statistical analysis of the assembled results of the four collaborators indicated that both methods are accurate enough and precise enough to be useful, and that for routine test-

ing two or three samples are probably sufficient for the sulfuric acid method and from three to five for the aluminum chloride method. The results obtained by the sulfuric acid method were generally higher, but it is considered preferable, since it is more convenient and less time consuming.

**Research to increase the use of cotton—a symposium.** [U. S. D. A.] (*Jour. Home Econ.*, 32 (1940), No. 7, pp. 443-454).—The following papers are presented: Cotton Fabric Research in the Bureau of Home Economics, by R. O'Brien; (pp. 443-447); Domestic Utilization of Cotton in Relation to Economic Conditions in the South, by R. J. Cheatham (pp. 447-451); and The Importance of Chemical Finishing in Increasing the Consumption of Cotton Textiles, by W. M. Scott (pp. 451-454).

**A critical study of some factors affecting the breaking strength and elongation of cotton yarns.** H. F. SCHIEBER and R. S. CLEVELAND (*Jour. Res. Natl. Bur. Standards* [U. S.], 27 (1941), No. 3, pp. 325-342, figs. 6).—"The results of single-strand tests to determine the breaking strength and elongation of cotton yarns varying in yarn number and spun with four twist multipliers are reported. Pendulum and inclined-plane types of testing machines and two rates of loading were used in the tests. The results give information regarding the corrections of these machines, variability of the yarns, and the number of tests required for a given precision and probability. The effect of rate of loading on the breaking strength and elongation is discussed. The tests on the inclined-plane machine yielded a significantly higher breaking strength and lower elongation than the tests on the pendulum machine. These unexpected differences are not attributable to a difference in the rates of loading between the two machines. They are explainable on the basis of the mechanics of the two types of machines."

**Physical properties of women's full-fashioned hosiery knit from commercial cotton yarns.** M. B. HAYS, E. C. PETERSEN, and D. A. TAYLOR. (U. S. D. A.). (*Jour. Home Econ.*, 32 (1940), No. 7, pp. 467-474, fig. 1).—This study is summarized by the authors as follows:

"The 43 styles of especially designed hose analyzed in this study are in weights that are suitable for outdoor work, active and spectator sports, and street wear. The appearance of these hose is decidedly better than the usual circular-knit cotton hose, since all styles are full-fashioned and are knit from combed, mercerized, gassed yarns in attractive colors.

"In lieu of serviceability studies, bursting strength and the test for elastic properties of hose are the best indicators of wearing quality. Bursting strength is found to depend on yarn number, gage, and pattern stitch. Hose with stretch tops, when evaluated by the load required to stretch hose from 19.2 to 20.2 in. circumference (s'-s), are more easily stretched than are the hose knit from the same yarn with a plain top. The reduced distortion and bagginess with a stretch top would give greater satisfaction in use. As measured by bursting strength and the hosiery test for elastic properties, the hose designed by the Bureau of Home Economics are equal or better than the 2 styles of full-fashioned hose purchased on the retail counter.

"This study shows that suitable cotton hose can be made in attractive colors with acceptable color permanence, that the stretch welt reduces the bagginess, and that certain designs will reduce the mottled effect often apparent in cotton hose and still have a reasonably high bursting strength."

**Clothing for school-age boys, girls.** A. BOWIE (*Miss. Farm Res. [Mississippi Sta.]*, 4 (1941), No. 10, pp. 1, 8).—This brief analysis of 256 clothing inventories of grammar school and high school boys and girls in a fair sample of rural families in various representative areas in Mississippi is concerned with articles

of outer clothing (excluding gifts) owned by the majority of the members of the four school-age groups. The data, showing number and percentage having each garment, the average cost per garment, and the average number owned per person, indicate that on the whole all four groups were tastefully and economically dressed, and that if there was an apparent inadequacy in clothing supplies it was perhaps in a lack of warm and waterproof clothing, particularly for grammar school boys and girls.

## HOME MANAGEMENT AND EQUIPMENT

**A handbook of home decoration**, W. R. and H. A. STOREY (*Pelham, N. Y.: Bridgman Pub., [1941], pp. 208, [figs. 71]*).—Basic ideas of decoration—good design, harmonious color, effective texture, and unity of one decorative detail with another—are considered, together with the more practical matters of use, economy, and durability. Selection of furniture, room arrangement, color, walls, floors and rugs, fabrics, decorative accessories, curtains and slip covers, period styles, and economy in decorating are given consideration.

## MISCELLANEOUS

**The rise of the United States Department of Agriculture**, T. S. HARDING. (U. S. D. A.). (*Sci. Mo., 53 (1941), No. 6, pp. 554-564*).—A historical sketch of the background, initiation, and development of the Department of Agriculture to its modern streamlined form which "has made it an invaluable agency in operating the National Defense Program, for it has ready at hand the organization and the machinery to do effectively many tasks which were neglected or were undertaken hastily in emergency set-ups during the World War."

**1941 Supplement to laws applicable to the United States Department of Agriculture**, J. K. KNUDSON (*U. S. Dept. Agr., 1941, pp. VI+664*).—This supplement to the 1935 edition (E. S. R., 75, p. 735) embraces statutes of a permanent character, reorganization plans, and Executive orders affecting the Department of Agriculture which were not included in the 1935 edition or which have been enacted or issued between September 6, 1935, and January 13, 1941.

**List of bulletins of the agricultural experiment stations for the calendar years 1939 and 1940**, C. E. PENNINGTON (*U. S. Dept. Agr., Misc. Pub. 459 (1941), pp. 86*).—This list, arranged by States and containing author and subject indexes, supplements that previously noted (E. S. R., 82, p. 859).

**Sixtieth Annual Report of the New York State Agricultural Experiment Station**, [1941], P. J. PARROTT (*New York State Sta. Rpt. 1941, pp. 84*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Mississippi Farm Research, [October-November 1941]** (*Miss. Farm Res. [Mississippi Sta.], 4 (1941), Nos. 10, pp. 8, figs. 10; 11, pp. 8, figs. 2*).—In addition to articles noted previously or elsewhere in this issue, No. 10 contains Coordination of Agricultural Work Effectuated Through New School of Agriculture (pp. 1, 8); and Dairymen Have Major Interest in Program To Increase Oat Crop, by J. S. Moore (p. 2); No. 11, Plant Diseases—Nature, Cause, Control, by J. A. Pinckard, Jr. (pp. 1, 2); Preventing Growth of Horns on Cattle, by W. C. Cowser (pp. 1, 2); Feeding the Suckling Pig, by P. G. Bedenbaugh (p. 1); Grades of Feeder Calves on Mississippi Rations, by A. E. Cullison (pp. 1-2); Control of Insect Pests (p. 3); Livestock Feeding and Management (p. 4); Prices Plague Vegetable Growers (p. 4); and Poultry Production for Home or Market (p. 6).

## NOTES

---

**Arkansas University and Station.**—The resignations are noted of Dr. L. M. Humphrey, professor of agronomy; H. M. Laude, assistant professor of agronomy; Dr. N. W. Hilston, instructor and assistant in animal industry; F. H. Vogel, instructor and assistant forester; and C. R. Pinckley, scientific assistant at the Fruit and Truck Branch Station. Arlon G. Hazen, instructor in agricultural engineering and assistant agricultural engineer, has been granted leave of absence for military service. Recent appointments include D. Boyd Shank as assistant professor of agronomy and agronomist, J. O. Dockins and Lawrence O. Fine as instructors in agronomy and assistant agronomists, Lorin E. Harris as instructor and assistant in animal industry, and Stewart Rowe, H. C. Anshutz, and Amos Underwood as scientific assistants in the Cotton, Livestock and Forestry, and Fruit and Truck Branch Stations, respectively.

**Colorado College and Station.**—Dr. Lindsey A. Brown, associate station agronomist in charge of soil surveys, has been granted a year's leave of absence to become special consultant in soils with the U. S. D. A. Farm Security Administration at Denver. His work has been taken over by Dale S. Romine, instructor and assistant in soils. Max E. Tyler has been appointed assistant bacteriologist, and Leroy Van Horn, assistant in wool technology.

**Delaware University and Station.**—Dean and Director Charles A. McCue, associated with the institution from 1907 until his retirement in 1939, died January 12 in his sixty-third year. He was a native of Michigan and a graduate of the Michigan College in 1901 and instructor in horticulture and assistant horticulturist there from 1904 to 1907. He had also served with the U. S. D. A. Forest Service. In Delaware he headed the horticultural work until 1920 and subsequently was director of the station, director of extension, and dean of the School of Agriculture. All these branches of the university developed steadily under his administration. His horticultural research was extensive and dealt especially with pomology and the role of plant food elements in orchard fruits. He served as president of the American Society for Horticultural Science in 1918. He had also been active in the Association of Land-Grant Colleges and Universities, serving as secretary in 1927 and as editor of its proceedings from 1928 to 1936.

**Georgia Station.**—A fireproof brick barn for seed storage has been completed. This building includes cotton and peanut breeding laboratories, a ginning room, storage space for 400 tons of grain, individual storerooms, and complete cleaning and treating equipment for grain.

S. R. Cecil has been appointed assistant food technologist in the department of food processing, succeeding I. T. Olsen, resigned to take up graduate work at the Massachusetts Institute of Technology.

**Purdue University and Indiana Station.**—James Troop, connected with the institution for more than 57 years and widely known as a pioneer horticulturist and entomologist, died at Urbana, Ill., on October 14, 1941, at the age of 88 years. A native of New York, Prof. Troop was graduated from the

Michigan College in 1878 and received the M. S. degree there in 1882. He came to Purdue in 1884 as head of the department of horticulture and entomology and in addition taught forestry, botany, and veterinary science. In 1912 the department was divided, but he continued as head of the department of entomology until 1920, when he became professor emeritus. He was also the first State entomologist of Indiana and in charge of its regulatory work from 1899 to 1907.

**Kansas College and Station.**—Wilmer E. Davis, associated with the botanical work of the institution since 1909 and professor of plant physiology since 1927, died January 17, aged 75 years. Born in Ohio in 1867, he was graduated from the University of Illinois in 1903. In addition to his instruction work he had given much attention to studies of seed germination.

**Kentucky Station.**—Recent appointments include Drs. Ladd N. Loomis and Woodrow Wilson Matthews as assistant veterinarians, Wilson Lowry Wright as instructor and assistant in animal husbandry, and William Bailey Cherry as assistant in bacteriology.

**Massachusetts College and Station.**—Dr. Edward B. Holland, research professor of chemistry, retired on January 13 after nearly 50 years' continuous service in agricultural chemistry. In the words of a recent communication from the station, "Dr. Holland is recognized for his contributions to dairying as related to information especially pertinent to butterfat. His contributions in the field of fungicides are very extensive, especially where these pertain to perfections in the use of copper sulfate. During the latter period of his service he has been especially devoted to analytical refinements in the determination of trace elements in connection with plant and animal (including human) nutrition."

Merrill J. Mack, professor of dairying, died February 9, aged 39 years. He was a native of Pennsylvania, graduating from the Pennsylvania College in 1923 and receiving the M. S. degree from the University of Wisconsin in 1925. He came to the college in 1923. In addition to instruction he had worked especially on the utilization of cream and other dairy products, including the vitamin C content of fruit ice creams and dairy beverages.

Dr. Chester E. Cross has been appointed assistant research professor of cranberry culture.

**Montana College and Station.**—The resignations are noted of Donald R. McCormick as assistant in chemistry to accept a similar position with the Washington College; Dr. Alva M. Schlehuber as associate professor and associate in agronomy to become associate geneticist at the U. S. Sugar Plant Field Station at Meridian, Miss.; and Thomas D. Watkins, Jr., as instructor in animal industry to respond to Army Service. Dr. Vincent E. Iverson, associate professor of horticulture, has been granted indefinite leave of absence for Army Service, beginning January 22.

**New York State Station.**—Extensive investigations on the nutritive values of dehydrated vegetables have been begun in the chemistry division as part of a cooperative project of the U. S. D. A. Bureau of Home Economics and in which Cornell University, the University of Texas, and the University of California are also participating. "For the present, the work here will have to do chiefly with (1) determination of the losses of vitamins and other nutrients of vegetables during dehydration, (2) losses of vitamins during storage of dehydrated vegetables, and (3) the degree of scalding prior to dehydration required to insure maximum vitamin retention and development of a simple laboratory method to indicate when the proper degree of scalding has been attained. Consideration will also be given to varietal adaptability to dehydration when freshly harvested vegetables are available on the station farm."

**North Carolina College and Station.**—The college department of animal industry has been reorganized, and Dr. A. O. Shaw, associate professor of dairy husbandry at the Kansas College and Station, has been designated as its head. R. H. Ruffner has been given charge of teaching in animal industry; Earl H. Hostetler of the work dealing with swine, beef cattle, sheep, meats, and work stock; and Dr. C. D. Grinnells of the division of dairying and the animal disease research. A division of animal nutrition, physiology, and genetics is to be added.

Dr. Ralph W. Cummings, associate professor of soil technology in the Cornell University and Station, has been appointed head of the department of agronomy beginning February 1. Borden S. Chronister has been appointed assistant agronomist vice H. D. Morris, resigned, and will carry on soil fertility work with peanuts, cotton, soybeans, and other cash crops.

**North Dakota College and Station.**—In a reconstruction of its hog barn, the station has provided two warm-air ducts a foot apart under a concrete floor of half of the farrowing pens. Warmed air is driven through these ducts by means of a fan. Comparisons are being made of the development of litters with the heated and unheated floors.

D. L. Hume, administrative assistant to the dean of the School of Agriculture and director of the station, has been called to military service. James R. Dice, dairy husbandman, has been designated administrative assistant to the dean and director during his absence.

**Ohio Station.**—A fruit products laboratory building has been completed.

Dr. W. E. Krauss has been appointed chief of the dairy department, succeeding C. C. Hayden, who becomes associate, with Dr. W. E. Pounden as assistant. Other appointments include Dr. L. H. Snyder as associate in animal industry and Dr. David C. Rife and Lawrence E. Kunkle as assistant and part-time assistant in the same department. John A. Alger has been appointed assistant in horticulture vice Joshua Crouse, called for military service.

**Oklahoma College and Station.**—The station observed its fiftieth anniversary during the golden celebration of the college from December 13 to 15, 1941. Dr. Henry G. Knight, Chief of the U. S. D. A. Bureau of Agricultural Chemistry and Engineering and director of the station from 1918 to 1921, was one of the principal speakers, representing the research activities of the land-grant colleges and taking as his subjects Future Markets for Farm Products and Chemists and Engineers in Agriculture.

Walter A. Krienke has been appointed assistant professor of dairy manufacturing and J. H. Hetrick instructor and superintendent of the creamery. Herman Hinrichs has succeeded L. G. McLean, resigned, as instructor in horticulture.

**Pennsylvania College and Station.**—Dr. Max Kriss, associated with the Institute of Animal Nutrition since 1918 and in recent years professor of animal nutrition, died November 16, 1941, at the age of 47 years. A native of Russia, he came to this country in 1910 and received the B. S. degree from the college in 1918 and the M. S. degree in 1920 and the Ph. D. degree from Yale University in 1936. His work had dealt especially with the energy metabolism and ventilation requirements of domestic animals, the net energy values of feeding stuffs, and the influence of nutrient compounds, especially amino acids, on the heat production of animals. He was the author or coauthor of more than 50 papers dealing with animal nutrition.

Recent appointments include Dr. Newell A. Norton as assistant professor of forest products and Lydia Tarrant as assistant professor of nutrition extension

**Rhode Island Station.**—Dr. T. E. Odland, head of the department of agronomy, has been given military leave of absence. Dr. Esther L. Batchelder has resigned as director of home economics to accept a position with the U. S. D. A. Bureau of Home Economics.

**Washington College and Station.**—Additional land, amounting to 240 acres, has been purchased for the Irrigation Branch Station at Prosser. The new tract is 2 miles north of the station and located on the Roza irrigation project. It will be used for experimental work on irrigated crops and irrigation methods and practices.

Dr. Enoch A. Bryan, in the words of a recent statement from the institution "long known as the guiding genius of the early-day expansion of the station and college," died November 6, 1941, at the age of 86 years. A native of Indiana, he went to Washington in 1893 as president of the college and director of the station and continued as station head until 1907 and as president until 1916. From 1917 to 1923 he was commissioner of education for the State of Idaho, returning to Washington in the latter year as research professor of economics and in 1929 retiring as president emeritus.

Dr. A. B. Caster has been appointed assistant chemist in the division of home economics. Dr. Stewart A. Fuller has succeeded Dr. Lyle G. Nicholson, resigned, as assistant veterinarian.

**Wisconsin University and Station.**—The department of animal husbandry has been reorganized to provide for divisions of meats and swine breeding and feeding. Dr. John M. Fargo and O. Burr Ross have been placed in charge of these divisions. Joseph Elfner has been appointed extension landscape specialist vice L. G. Holmes, resigned to enter commercial work. Norman S. Lundquist has been appointed instructor in dairy husbandry.

To meet the emergency caused by the withdrawal for war work of 60 W. P. A. employees engaged in laboratory and clerical assistance, an elective service has been organized for university students. Over 200 volunteers have been obtained for part-time work, and it is expected that others will be needed for the full success of the program.

**Wyoming University and Station.**—Dr. J. L. Morrill, vice president of Ohio State University, has been appointed president as of January 1. J. A. Gorman, assistant professor of animal production and assistant animal husbandman, has been called to military service. Dr. Wendell L. Bartholdi has been appointed assistant professor of agronomy and assistant agronomist.

**New Journals.**—*The Nyasaland Agricultural Quarterly Journal* is being published at Blantyre, Nyasaland, by the Nyasaland Tea Association, Ltd., replacing *The Nyasaland Tea Association Quarterly Journal*. The Agricultural Department of Nyasaland is cooperating in its publication, and the initial number contains an article by A. S. Richardson, Director of Agriculture, entitled *Wartime Agriculture in Nyasaland*.

*The Land* is being published quarterly at 1721 Eye Street, N. W., Washington, D. C., by Friends of the Land, "a nonprofit, nonpartisan society for the conservation of soil, rain, and man." The initial number contains numerous brief articles, among them *Soil Defense*, by Vice President Henry A. Wallace.

## ISABEL BEVIER, A PIONEER IN HOME ECONOMICS EDUCATION AND RESEARCH

In the words of a recent statement from the University of Illinois, the career of Dr. Isabel Bevier, who died in Urbana on March 17, 1942, "paralleled the rise of the profession of home economics." It might appropriately be added that for much of her 82 years she was a leader and active participant in that movement, and her contributions in the triple fields of collegiate instruction, extension, and research were timely and significant.

Born in Plymouth, Ohio, on November 17, 1860, she was graduated from the University of Wooster in 1885 and 2 years later received there the degree of master of philosophy in Latin and German. Her interests seem to have been primarily in science, however, for after some high school teaching and administration she became in 1888 professor of natural science in the Pennsylvania College for Women, leaving this position in 1897 for a brief service as professor of chemistry in Lake Erie College.

Characteristic of her development during this period was her continued study of chemistry at a wide range of institutions. Summers were spent at the Case School of Applied Science, Harvard University, and Wesleyan University, and there was a year at Western Reserve University and some time at the Massachusetts Institute of Technology devoted to the chemistry of foods. Of particular significance was her 1894 summer at Wesleyan University in the laboratory of Professor W. O. Atwater and under the immediate supervision of Drs. Charles D. Woods and C. F. Langworthy, all of whom became prominently identified with human nutrition studies. At that time the initial appropriation of \$10,000 had just been made by Congress for investigation and report by the Federal Department of Agriculture on "the nutritive value of the various articles and commodities used for human food." This inquiry had been assigned to the Office of Experiment Stations and delegated to Dr. Atwater. As one result of her contacts with him, Dr. Bevier was commissioned to carry on a series of dietary studies for the Office of families in different stations of life in Pittsburgh and about 5 years later of

a group of students in Lake Erie College. These studies were among the earliest of their kind in this country.

In 1900 she was appointed in charge of a new department in the University of Illinois which became known as the department of household science. At its creation, we are told, "not only was the department nameless, but there also was no precedent and no textbook for it." In making the appointment, President Andrew Sloan Draper announced that the department "will be judged by the results obtained in its laboratories and classrooms and its success by the measure of university respect obtained for it." The first class, with three members, was graduated in 1903. In 1918 there were 94 graduates. During the 21 years of her active administration as head of the department, more than 5,000 women were enrolled in its courses.

As would be expected from her scientific background and associations, Dr. Bevier was consistently interested in home economics research. Her initial work in Illinois dealt especially with methods of roasting beef, supplementing the extensive meat studies then under way at the university by Dr. H. S. Grindley of the department of animal husbandry. Among its concrete accomplishments was the progress made in standardization of the conditions of roasting through temperature control of the oven and the use of a clinical thermometer to determine the internal temperature of the meat and the end point of any desired doneness. She was also successful in securing in 1908 the appointment of a research assistant in home economics who is believed to have been the first full-time research worker in that subject in a land-grant institution.

Dr. Bevier also took a leading part in home economics extension, serving as vice director in Illinois from 1915 to 1921 and again as acting vice director from 1929 to 1930. Her leadership thus included both the pioneer days and the First World War period. During that war she was associated with the U. S. Food Administration and other groups as a home economics representative.

The period from 1921 to 1929 was largely spent in home economics work in the southern branch of the University of California and the University of Arizona, but she returned to Illinois in the latter year as professor of home economics. In 1930 she retired as professor emeritus.

In an evaluation of Dr. Bevier's work, special mention should be made of her influence upon others. Much of this was exerted personally and through two groups—the American Home Economics Association and the Association of Land-Grant Colleges and Universities. She was prominently identified with the formation of the Home Economics Association, serving as its second president, and with the early management and policies of its *Journal of Home Economics*.

Her standing in the Association of Land-Grant Colleges and Universities is indicated by her service in 1919 as chairman of the home economics division of the college section, and her designation in 1919 as the representative of home economics on the special committee for the reorganization of the association itself, which resulted in the establishment of a section of home economics coordinate with agriculture and engineering.

Still another sphere of influence was through her writings. In addition to many shorter bulletins and articles, these included the pioneer texts entitled *Home Economics Movement*, *Food and Nutrition*, and *Selection and Preservation of Food (Laboratory Manual)*, all brought out, with the assistance of others, in 1906 and 1907, and *The House—Plan, Decoration, and Care*, which appeared in the latter year. Most of these books were issued in several editions and were of much value in giving perspective to the new movement and bringing its pedagogic material into concrete form.

Dr. Bevier's work received much recognition, including the bestowal of honorary degrees of doctor of science by the Iowa State College in 1920 and the University of Wooster in 1936. Many appreciative tributes have also appeared, from which parts of two may be quoted. One of these, by Miss Lita Bane, a successor at the university, points out that "Miss Bevier stood out preeminently for her scholarly standards, being consistently unwilling to offer college courses devoted almost entirely to skills, unwilling to mortgage the student's time with specialized home economics subjects to the point where courses in economics, literature, and art were crowded out, and always standing for a liberal college course with a major only in home economics." The other by the late Dr. Lafayette B. Mendel, of Yale University, fittingly epitomizes her work in the statement that "Miss Bevier belonged to that important group of American women, trained in an atmosphere of science, who ventured to give direction to the new home economics movement in a modern, constructive way. She was one of the pioneers who endeavored to translate current scientific research into the language of everyday life. This called for courage in the face of traditional resistance to change, for vision and faith in what seemed to be unwarranted innovation, and for real leadership."

## RECENT WORK IN AGRICULTURAL SCIENCE

### AGRICULTURAL AND BIOLOGICAL CHEMISTRY

**Fractionation of waxy and ordinary cornstarch,** C. G. CALDWELL and R. M. HIXON. (Iowa State Col.). (*Jour. Amer. Chem. Soc.*, 63 (1941), No. 11, pp. 2876-2880, figs. 2).—The ratio of soluble to insoluble components separated from ordinary cornstarch pastes by electrodialysis or by freezing was found to depend upon the extent of peptization. Retrogradation or aging of starch pastes was shown by the definite X-ray patterns to be a crystallization process. A comparison of the physical properties of the limit dextrans obtained from waxy and ordinary cornstarch by digestion with  $\beta$ -amylase indicated rather a close similarity than a chemical difference between them. Somewhat similar quantities of dimethyl glucose were obtained by hydrolysis of methylated cornstarch (0.93 percent) and of the methylated limit dextrin (0.87 percent). If branching exists in the original starch, such linkages are hydrolyzed by the  $\beta$ -amylase.

**The comparative baking qualities of starches prepared from different wheat varieties,** R. H. HARRIS and L. D. SIBBITT. (N. Dak. Expt. Sta.). (*Cereal Chem.*, 18 (1941), No. 5, pp. 585-604, figs. 8).—The starch of each variety to be tested was washed out in dilute sodium phosphate buffer solution, permitted to settle, separated, and dried at from 90° to 94° F., after which it was mixed with a suitable quantity of dried gluten, sugar sufficiently in excess of that used in ordinary doughs to compensate the loss of the water-soluble carbohydrates in the flour, and the remainder of the usual dough components. The percentage of gluten in the mixture had a predominant influence upon the loaf volume, but distinct differences in baking quality among the starches from five varieties of hard red spring wheat are shown in the external appearances, cross sections, and volumes of the baked loaves.

**Comparative baking quality of wheat starches,** R. H. HARRIS and L. D. SIBBITT (*North Dakota Sta. Bimo. Bul.*, 4 (1941), No. 2, pp. 2-6, figs. 4).—This is condensed from the paper noted above.

**The constitution of arabo-galactan.—I, The components and position of linkage,** E. V. WHITE. (Univ. Idaho). (*Jour. Amer. Chem. Soc.*, 63 (1941), No. 11, pp. 2871-2875).—The reproducibility of "arabo-galactan," a water-soluble gum present in larch wood, *Larix occidentalis*, was demonstrated by conversion to the fully acetylated derivative followed, after purification, by saponification to the original compound. The methyl ether of arabo-galactan upon treatment with methyl-alcoholic hydrogen chloride yielded the glycosides of 2,4-dimethyl-*d*-galactose, 2,3,4-trimethyl-*d*-galactose, 2,3,4,6-tetramethyl-*d*-galactose, and 2,3,5-trimethyl-*l*-arabinose, showing that both 1-3 and 1-6 oxygen linkages are present in the parent compound and that a substantial proportion of the galactose units are linked at both the 3 and 6 positions. A branched chain structure, terminated by residues of galactopyranose and arabofuranose, is indicated.

**The preparation of  $\Delta^7$ -,  $\Delta^8$  (<sup>14</sup>)- and  $\Delta^{14}$ -cholestenes,** J. C. ECK and E. W. HOLLINGSWORTH. (Iowa Expt. Sta.). (*Jour. Amer. Chem. Soc.*, 63 (1941), No. 11, pp. 2986-2990).— $\Delta^8$ -,  $\Delta^8$  (<sup>14</sup>)- and  $\Delta^{14}$ -cholestenes were prepared and the struc-

ture of  $\Delta^8$ -cholestene was established by its conversion to cholestan-7-one. The normal hydrogenation and the consumption of bromine and of perbenzoic acid by cholestenes were compared. The specific rotations of  $\Delta^8$ ,  $\Delta^8(14)$ - and  $\Delta^{14}$ -cholestenes were found to be in agreement with the specific rotations of the analogous  $\Delta^8$ ,  $\Delta^8(14)$ - and  $\Delta^{14}$ -unsaturated steroid derivatives, respectively ( $\delta$ -,  $\alpha$ - and  $\beta$ -stenols, respectively).

**The structure of "7-dehydrocholestene isomer,"** J. C. ECK and E. W. HOLLINGSWORTH. (Iowa Expt. Sta.). (*Jour. Amer. Chem. Soc.*, 63 (1941), No. 1, pp. 107-111).—The product obtained by the action of quinoline on 5,6-dibromocholestan-3 is indicated to be an inseparable mixture of  $\Delta^{4,6}$ -cholestadiene and coprostene. 7-Dehydrocholestene isomer is indicated to be  $\Delta^{4,6}$ -cholestadiene. The Wolff-Kishner reduction product of the semicarbazone of  $\Delta^{4,6}$ -cholestadiene-3 is indicated to be an inseparable mixture containing  $\Delta^{4,6}$ -cholestadiene. The specific rotation of  $\Delta^{4,6}$ -cholestadiene is  $+4.27^\circ$ . An additional double bond in the 3,4-position in cholestene or in the 6,7-position in coprostene effects a marked increase in levorotation.  $\Delta^{4,6}$ -Cholestadiene was found to be rearranged to  $\Delta^{3,5}$ -cholestadiene by treatment with dry hydrogen chloride in chloroform.

**Methyl esters of the higher fatty acids,** F. W. WYMAN and C. BARKENBUS. (Univ. Ky.). (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 11, pp. 658-661, figs. 5).—The methyl esters of caprylic, capric, lauric, myristic, palmitic, and stearic acids were purified and their refractive indices determined. Small quantities of known mixtures of these esters were fractionally distilled through a spinning-band column and their composition was determined. With the exception of the more volatile esters, the determinations are held to be fairly accurate considering the difficulty connected with separating such mixtures. In oil analyses where only small quantities of these acids are available, this method offers the first convenient and fairly accurate method of analysis.

**The isolation of p-aminobenzoic acid from yeast,** K. C. BLANCHARD (*Jour. Biol. Chem.*, 140 (1941), No. 3, pp. 919-926).—p-Aminobenzoic acid was obtained from a commercial aqueous alcohol extract of yeast by alcohol-ether extraction, followed by purification of the extract, through congelation of some insoluble material of apparent lipid nature and defecation with basic lead acetate and subsequent extraction with ether. The ether extract, after purification, treatment with water, and evaporation at a low temperature not exceeding  $35^\circ$  [C.], yielded crystals of the product which were purified by recrystallization from hot water. The p-aminobenzoic acid was also obtained from yeast by a modified procedure involving the formation of the slightly soluble acetyl derivative, which was extracted with an alcohol-ether mixture. Recovery was made from this solution through a series of purification steps ending with sedimentation of the p-acetylaminobenzoic acid from an ether extract adjusted to pH 3.8. A yield of 2.1 mg. was obtained from 600 gm. of plasmolyzed and heated yeast, while 3.7 mg. was obtained from a like quantity of autolyzed yeast. This increase in yield upon autolysis suggested that yeast contains a free and a combined form of the p-aminobenzoic acid. Identity of all crystalline products obtained was established by mixed melting point determinations.

**The molecular constitution of an insoluble polysaccharide from yeast, Saccharomyces cerevisiae,** W. Z. HASSID, M. A. JOSLYN, and R. M. MCCREADY. (Univ. Calif.). (*Jour. Amer. Chem. Soc.*, 63 (1941), No. 1, pp. 295-298, fig. 1).—The low specific rotations of the acetylated and methylated derivatives and the upward mutarotation during hydrolysis suggested that the glucosidic linkages of the anhydroglucose units are predominantly of the  $\beta$ -type. On methylation and subsequent hydrolysis of the polysaccharide 2,4,6-trimethylglucose was obtained as the sole product of hydrolysis. No end-group (tetramethylglucose)

could be detected, a possible indication that the molecule is probably of the closed chain type. The molecular weight of the polysaccharide determined by the Staudinger viscosity method was approximately 6,500.

**The preparation of coenzyme I from yeast**, S. WILLIAMSON and D. E. GREEN (*Jour. Biol. Chem.*, 135 (1940), No. 1, pp. 345-346).—A hot water extract of yeast is defecated with basic lead acetate, the clear filtrate is adjusted to pH 6.5 with 10 percent acetic acid, and the coenzyme is precipitated with silver nitrate. The washed precipitate, suspended in water, is decomposed with hydrogen sulfide, and following filtration and aeration to remove silver and hydrogen sulfides, the enzyme is precipitated by pouring the aqueous solution into 5 volumes of acetone in the cold and permitting to stand 2 hr. The product obtained by this method was estimated to be about 63-68 percent pure, as judged by spectrophotometric and total phosphorus determinations.

**Stability of prothrombin in the presence of thrombin**, J. H. FERGUSON (*Soc. Expt. Biol. and Med. Proc.*, 46 (1941), No. 1, pp. 80-83, fig. 1).—Evidence is presented to indicate that "thrombin and (citrated) prothrombin can co-exist with no more destruction of either than can readily be attributed to the natural instability of both preparations," and that "thrombin itself is neither an activator nor a destroyer of prothrombin."

**Protein-digesting enzymes of papaya and pineapple**, A. K. BALLS (*U. S. Dept. Agr. Cir.* 631 (1941), pp. 9, figs. 3).—The preparation and present uses of papain and the possible uses of bromelain are discussed. A method of obtaining bromelain from pineapple juice, expressed from the peelings and cores of the fruit, without losing the value of the sugar is suggested. The enzyme may be precipitated by the addition of alcohol to the third press juice, not particularly valuable to the canner, leaving the sugar in solution. The use of papain in tenderizing meat and the possible use of bromelain are discussed. A method developed by the Department for the manufacture of a cleaner and more active preparation of commercial papain than that ordinarily sold today has at least doubled the yield of enzyme from a papaya tree by preventing the loss of enzyme that takes place in the present process of manufacture. Methods for preparing two proteolytic enzymes in the crystalline form from crude papain have also been developed. These preparations are too expensive for ordinary use, but they may be of service in medicine.

**The nature of the liberation of bound barley amylase as affected by salt solutions**, M. F. DULL and R. G. SWANSON (*Cereal Chem.*, 18 (1941), No. 1, pp. 113-120).—Experimental evidence indicates that the bound amylase of barley, as released by salt solutions, is released as a result of the peptization of the proteins to which the enzyme is thought to be adsorbed or bound.

**The effect of wheat type, protein content, and malting conditions on the properties of malted wheat flour**, W. F. GEDDES, F. C. HILDEBRAND, and J. A. ANDERSON. (Minn. Expt. Sta.). (*Cereal Chem.*, 18 (1941), No. 1, pp. 42-60).—Growth and yield of malt were not affected by wheat type or protein content. Increasing the steeping level and germination time resulted in greater growth and lower yield. Raising the kilning temperature decreased yield slightly. Protein content of malted wheats and of flours experimentally milled therefrom decreased with conditions which tended to increase growth, the effect being greater for flours. In general, decrease in ash was not significant. Amylase activity was influenced by all factors investigated except kilning. Increase in germination time and steeping level and the use of hard red spring wheat rather than durum raised amylase activity. The highest activity was obtained with high-protein hard red spring wheat steeped to 44 percent moisture and germinated 5 days. Autolytic protease activity of the malted wheat flour

was increased with longer germination, higher steeping level, higher protein, and with durum wheat. The effect of steeping was conditioned by protein level and germination time, and the last two factors were influenced by steeping level. Amylase and protease activity were significantly correlated ( $r = +0.676$ ). The ratio between these activities was markedly influenced by wheat type, protein content, steeping level, and germination time. At constant amylase activity, the lowest protease activity was obtained with low-protein hard red spring wheat steeped to 40 percent moisture and germinated 5 days. The results of baking tests were little affected by the variations studied.

**The application of the dropping mercury electrode to the study of oxidation-reduction systems in flour.** H. A. LAITINEN and B. SULLIVAN (*Cereal Chem.*, 18 (1941), No. 1, pp. 60-73, figs. 14).—A substance giving an anodic wave (indicating a reducing substance) was released from the gluten on treatment with sodium hydroxide but not from the starch. A variety of other treatments failed to liberate the substance. A buffered solution containing the alkali-treated wet gluten gave a positive test for mercury on electrolysis, indicating formation of a mercury complex. Certain RSH compounds give similar mercury complexes. The group giving that anodic wave may be some reduced sulfur linkage.

**Chemical composition of *Symphoricarpos rotundifolius* as influenced by soil, site, and date of collection.** L. A. STODDART. (Utah Expt. Sta.) (*Jour. Agr. Res. [U. S.]*, 63 (1941), No. 12, pp. 727-739, fig. 1).—*S. rotundifolius*, or round-leaf snowberry, was selected to represent the forage plants of the area under investigation (near Logan) as being palatable, abundant, and rather uniformly distributed over all soil types.

Date of collection was by far the most influential factor, late-season sampling resulting in a highly significant decrease in protein, nitrogen-free extract, total ash, phosphorus, and magnesium, and a highly significant quadratic influence upon calcium. Only crude fat failed to respond to season. Soil type had a highly significant influence upon total ash and phosphorus content and a pronounced though insignificant effect upon protein content. Site had a significant influence upon protein and a highly significant influence upon magnesium, protein being higher and magnesium lower on good sites. Nitrogen-free extract was also significantly higher on poor sites. Complex interactions between date of collection, site, and soil were often observed. Attention had, therefore, to be given to all before broad conclusions were drawn regarding the influence of any. Large error or variation was apparent in the analytical procedure for crude fat, and the field variability was especially high in crude fiber, nitrogen-free extract, and crude fat. For the determination of most components duplicate collection and duplicate analysis did not increase the accuracy to a degree commensurate with the extra expense incurred.

**The dimorphism of sulfathiazole.** D. C. GROVE and G. L. KEENAN (*Jour. Amer. Chem. Soc.* 63 (1941), No. 1, pp. 97-99, figs. 3).—Sulfathiazole (2-sulfanilamidothiazone) exists in dimorphic forms. Methods of preparation, melting points, optical properties, and photomicrographs are presented.

**Portable low-pressure gas tanks.** G. R. ROBERTSON. (Univ. Calif.). (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 11, p. 686, fig. 1).—The author gives specifications for a tank designed for pressures of 200 lb. or less, height from 35 to 40 in. and diameter 12 in., the tank having wheels which clear the floor by about  $\frac{1}{8}$  in. when the tank stands vertically, and a handle for tipping the tank onto its wheels and rolling it about. The device was found more convenient than those now on the market and was especially useful for combustion oxygen, for nitrogen used to provide an inert atmosphere, etc.

**Preparing asbestos for filtering mats, B. L. KASPIN.** (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 9, p. 517, fig. 1).—A wide-mouthed, square glass jar of about 2-qt. capacity is covered by a piece of moderately heavy cloth (ordinary laboratory towel material is suitable). A glass tube passes through a small hole in the cloth and is held in position by two tightly fitting rubber stoppers, one placed above and the other below the cloth. The tube should be placed near one corner of the jar and extend approximately halfway to the bottom. The outer end of the tube is connected to a compressed air line. Cut the asbestos to roughly 0.5-in. lengths, place a 0.25-in. layer of this material in the bottom of the jar, securely fasten the cloth cover, and gradually admit the compressed air. When the correct rate of flow is attained, the asbestos is lifted by the air currents and swirled violently. In about 5 min. the asbestos becomes fluffy and half fills the jar. If the air is admitted too rapidly the asbestos tends to rise and accumulate at the top of the jar. The apparatus should be used in a hood with a strong draft, since its operation produces a fine asbestos dust that is extremely irritating.

**Micro determination of some constituents of plant ash, M. E. WALL.** (N. J. Expt. Stas.). (*Plant Physiol.*, 15 (1940), No. 3, pp. 537-545).—The author describes micro methods found satisfactory for preparation of plant samples for mineral analyses, colorimetric determinations of phosphate, magnesium, potassium, sodium, and calcium, and gives data on the accuracy of the methods.

**Preparation of Nessler's reagent, A. P. VANSELOW.** (Calif. Citrus Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 9, pp. 516-517, fig. 1).—Nessler's reagent prepared according to formulas found in textbooks and papers may show slowness in the development of color, formation of a red precipitate, and the development of off colors, especially with low concentration of ammonia. From a study of the phase-rule diagram for this solution and from experimental investigation, the author concludes that a reagent should have 10 moles of potassium hydroxide for each equivalent of mercuric ion in solution with 5 percent excess of potassium iodide over and above that called for by the hypothetical compound potassium mercuric iodide. It should stand several days before being used to permit any precipitate to settle out. There is no necessity of using involved methods of preparation. The author recommends that 45.5 gm. of mercuric iodide and 34.9 gm. of potassium iodide be dissolved in as little water as is needed, 112 gm. of potassium hydroxide (140 cc. of a solution, sp. gr.  $\frac{15^\circ}{4^\circ}=1.538$ ) added, and the whole diluted to 1 l

This solution is 0.2 N with respect to the mercury content. In the Nessler test, 5 cc. of this reagent to 100 cc. of final volume are used, and the color comparisons with the standards are made 30 min. after mixing. Nessler's reagent prepared according to this formula has been used for several years with completely satisfactory results.

**Notes on the colorimetric determination of traces of cobalt, I. A. BLACK** (*Soil Sci.*, 51 (1941), No. 5, pp. 387-390, fig. 1).—The quantitative colorimetric estimation of traces of cobalt by  $\alpha$ -nitroso- $\beta$ -naphthol appears possible provided acidity is controlled and the color of excess reagent is destroyed by treatment with sulfite. Color comparisons are valid even between solutions with considerably different cobalt contents. Iron can be removed without difficulty and without impairing the accuracy of the method. The use of sulfite for eliminating the color of the reagent appears to be a new procedure.

**A rapid method for the microanalysis of lead, L. T. FAIRHALL and R. G. KEENAN** (*Jour. Amer. Chem. Soc.*, 63 (1941), No. 11, pp. 3076-3079, fig. 1).—A rapid and precise evaluation of minute amounts of lead in drinking water and

in urine without the necessity of ashing involves extraction with dithizone, extraction from the chloroform layer with 2 percent nitric acid, precipitation as chromate, and iodometric titration of the chromate after solution in hydrochloric acid.

**Colorimetric determination of phosphate**, S. R. DICKMAN and R. H. BRAY. (Ill. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 11, pp. 665-668).—The authors describe a colorimetric method for phosphates which employs a molybdate-hydrochloric acid solution instead of a molybdate sulfuric acid solution. The results are not affected by chlorides or by the ferric ion up to 15 p. p. m. Fading is less rapid than in most methods. The method is applicable for phosphate determinations in soil fusions, hydrochloric acid extracts of soils, water analyses, oceanographic analyses, plant oxidations in which the sample is taken up in hydrochloric acid, and biological determinations.

**Detection and estimation of dihydroteneone in the hydrogenation products of rotenone**, L. D. GOODHUE and H. L. HALLER. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 11, pp. 652-654, fig. 1).—To develop a method for the determination of dihydroteneone in the mixture of hydrogenation products, some of the physical and chemical properties of these compounds were examined. A combination of physical properties gave some information as to the amount of dihydroteneone present, but a better method is based on the observation that this is the only reduction product giving an appreciable red color by the Goodhue test (*E. S. R.*, 76, p. 154).

**Physicochemical assay of vitamin A**, N. D. EMBREE (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 3, pp. 144-145).—It is pointed out that low results are often obtained in the assay of low-potency fish-liver oils, food products, and certain pharmaceutical preparations when the determination of vitamin A is carried out by measurement of the absorption of ultraviolet light (1) at the maximum (328  $m\mu$ ) of the vitamin A absorption band of an alcohol solution of the material or purified extract or (2) at the maximum (320  $m\mu$ ) of the absorption band of the blue-colored reaction product formed by mixing a chloroform solution of the material with 10 times its volume of a saturated chloroform solution of antimony trichloride. The poor results are generally attributed to the instability of vitamin A in dilute solution. To show that this instability is due to destruction of vitamin A by ultraviolet light, solutions of vitamin A containing from 20 to 25 U. S. P. units per cubic centimeter were divided into two portions. One portion was placed in an amber glass test tube and the other in a clear glass test tube, the tightly stoppered tubes then being exposed to daylight of cloudy days for a period of from 4 to 5 hr. on a bench 12 ft. from the window. Samples exposed in the clear glass tubes showed losses of vitamin A potency varying from 8 to 55 percent, whereas those stored in the amber glass showed little or no loss. Because of this destruction of vitamin A in dilute solutions exposed to light, it is suggested that laboratories performing assays for vitamin A in food, medicinal, and physiological preparations should have certain types of amber glassware, concerning which suggestions are made.

**Spectrophotometric determination of vitamin A: Critical study of applicability to fish liver oils**, D. T. EWING, J. M. VANDENBELT, A. D. EMMETT, and O. D. BIRD. (Mich. State Col. et al.). (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 11, pp. 639-644).—The Bausch and Lomb spectrophotometer and the Hilger vitameter used in a long series of determinations on seven fish-liver oils having a wide range in vitamin A potency gave reproducible results with good agreement between determinations by the two instruments. The following fundamentals of procedure were established:

The test reading should be made within 1 hr. after preparation of the solution for which either isopropyl or absolute ethyl alcohol may be used, since

the vitamin shows equal absorption in the two mediums. Cells should be carefully paired and kept scrupulously clean. A Hilger hydrogen tube, because of its constancy as a source of light, is preferable to a condensed spark, although the latter may be used if its position with respect to the optical axis can be maintained with precision. For visual comparison, optimum results are obtained if the photographic emulsion has been processed to a density of 0.6. Unsaturated long-chain fatty acids, particularly in low-potency oils, and metallic salts of fatty acids, such as copper oleate and ferric oleate, are interfering substances. The former may be removed by saponification and the latter eliminated through insolubility in isopropyl alcohol.

Analyses of the data showed that the mean of as few as two determinations gave a satisfactory result ( $\pm 2$  percent) with the spectrophotometer, but that a minimum of six tests was required to establish a satisfactory  $E_{1\%}^{1\text{cm}}$  value with the vitameter. Conversion factors calculated by correlating the spectrophotometer and vitameter data with those from biological procedure were in good agreement, the mean value for converting the  $E_{1\%}^{1\text{cm}}$  value to International Units per gram being 2,137.

**Spectrophotometric assay of vitamin A, with special reference to margarine,** J. R. ENISBURY (*Analyst*, 65 (1940), No. 774, pp. 484-492, figs. 3).—The application of spectrophotometric methods to the assay of vitamin A in margarines and the concentrates used in their vitaminization is described briefly with reference to apparatus, solvents and reagent, and examination of sample. Consideration is also given to limitations to estimation of potency, such as inhibitive and enhancement effects and irrelevant absorption, and to the interpretation of data.

**Spectrographic characteristics of vitamin A materials,** R. L. MACFARLAN, P. K. BATES, and E. C. MERRILL (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 11, pp. 645-647, figs. 4).—A study was made of the ultraviolet absorption of vitamin A as determined with a Littrow spectrograph having a Hilger Spekker ultraviolet photometer mounted in front of it and Hilger type J absorption cells for liquids (1 cm. in thickness) mounted in the photometer. A condensed spark between tungsten steel electrodes, accurately aligned through mounting on a de Gramont sparking stand, was used as a light source. Line intensities were read by means of a Zeiss spectrum line photometer. With this apparatus, permitting great accuracy of detail, the results obtained led to the following conclusions:

"There appears to be a continuous change in absorption of the U. S. P. reference cod-liver oil with use in the laboratory over an extended period of time, and as a standard for spectrographic measurements more rigid limitations are necessary than are now in use for biological assay. Fresh U. S. P. reference cod-liver oil gives good agreement with the absorption value published by other experimenters. Care must be exercised in using the spectrographic method to evaluate commercial cod-liver oils and concentrates because of the variability of the extraneous absorption. The distilled vitamin A esters show negligible change in their absorption properties upon saponification. Within experimental error the absorption curve shapes of the distilled vitamin A esters and the unsaponifiable fraction of the fresh U. S. P. reference oil are identical. Beer's law appears to hold over the wave-length range 3,100 to 3,500 a. u. of the vitamin A absorption curve."

**Extraction of carotene from plant material: A rapid quantitative method,** L. A. MOORE and R. ELY. (Mich. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 600-601, fig. 1).—Extraction is accomplished with 200 cc. of a foaming solvent consisting of a mixture of petroleum ether (43 percent

by volume) and 95 percent ethyl alcohol (57 percent by volume) preheated to 27° C. and added to from 1 to 4 gm. of the sample placed in the container of a food blender equipped with knives turned by a high-speed motor. The blender is run for 5 min., the solvent is removed from the residue, and sufficient water is added to dilute the alcohol to about 80 percent, thus permitting separation of the alcohol and petroleum ether phases. The residue and the alcohol are washed with petroleum ether. The combined petroleum ether extracts are washed with water to remove alcohol and then passed through a column of dicalcium phosphate to remove pigments other than carotene. The filtrate is made up to volume, and carotene concentration is evaluated with a photoelectric colorimeter. The method, recommended because of its rapidity and the consequent reduction of enzyme activity in fresh material, gives results in good agreement with those obtained by a previously published method (E. S. R., 85, p. 583) in which the sample is ground in a mortar with sand and refluxed for 1 hr. with alcohol. Values by both methods are reported for several hays, silages, and fresh green materials, including carrot root, dock and dandelion leaves, and leaves of a number of legumes and grasses.

The assay of vitamin B<sub>1</sub> (*Ontario Res. Found. Bul.*, 8 (1941), No. 3, pp. 5-9, figs. 4).—A review which briefly outlines the general principles involved in the various biological and biochemical assay methods of determining thiamin.

Riboflavin determination by the microbiological method, A. ARNOLD, S. T. LIPSUS, and D. J. GREENE (*Food Res.*, 6 (1941), No. 1, pp. 39-43).—The microbiological method of Snell and Strong (E. S. R., 82, p. 587) applied to extracts of natural and concentrated source materials was found to give fully satisfactory results as judged by (1) agreement of determinations at three significant levels, (2) agreement between separate samples, and (3) agreement with reported analyses of similar materials by the same method or by biological technics. Brewers' yeast, a fuller's earth adsorbate from rice bran concentrate with added whey adsorbate, a liver extract, a rice bran, and a processed rice bran averaged, respectively, 45.3γ, 81.3γ, 312.0γ, 4.0γ, and 2.85γ of riboflavin per gram. Two samples of dried skim milk averaged 15.9γ and 16.6γ per gram.

A method for the determination in vitro of riboflavin in tissues, F. O. VAN DUYNE (*Jour. Biol. Chem.*, 139 (1941), No. 1, pp. 207-218, figs. 2).—A number of existing in-vitro methods for determination of riboflavin in tissues were investigated and found unsatisfactory either because the riboflavin was not quantitatively extracted or because of the simultaneous extraction of substances interfering in the subsequent estimation of fluorescence. A new method was, therefore, developed and tested. The procedure, described in some detail, involved hydrolysis of the tissue (ground with sand) by incubation at 37° C. for 20 hr. with 0.3 percent pepsin and 0.2 percent HCl; extraction with water by boiling the above mixture and filtering; and determination of the intensity of fluorescence of the extract as measured by the use of the Klett fluorimeter, an instrument of the two-celled, balanced-circuit type so designed that the fluorescence of the unknown solution is measured in terms of the reference standard.

The results obtained by this method were compared with those obtained by bio-assay of the same tissues. The tissues investigated represented liver, kidney, heart muscle, and skeletal muscle of rats reared on different diets and contained, respectively, 4.0γ, 5.1γ, 15.0γ, and 23.0γ of riboflavin per gram. The feeding method employed was a modification of the Bourquin-Sherman quantitative determination of vitamin G, the response of the test animals being interpreted from a reference curve of response established for animals fed varying amounts (0γ-12γ six times a week) of riboflavin for 4 weeks. The method as developed for the extraction of riboflavin and its subsequent measurements in vitro was

found to be quantitative, although further modification was indicated for successful application to the determination of riboflavin in skeletal muscle. The feeding method used and the in-vitro method finally developed gave values that were without significant difference.

**A microbiological assay technique for pantothenic acid with the use of *Proteus morganii*.** M. J. PELCZAR, JR., and J. R. PORTER (*Jour. Biol. Chem.*, 139 (1941), No. 1, pp. 111-119, fig. 1).—The microbiological technic described involves the use of *P. morganii*, which responds to a smaller dose of pantothenic acid than any other organism hitherto reported. In the presence of as little as 0.0002  $\mu$ g. of synthetic calcium pantothenate per cubic centimeter of the assay medium visible growth occurs, thus making it possible to determine the pantothenic acid content of the material to be tested in such dilution that non-specific factors will not interfere with the reaction. The preparation of the inoculum, the basal medium, and the assay medium is described in detail, and the results are reported of the response of the organism to graded quantities of pure solutions of calcium pantothenate, the assay of extracts of natural substances, and the recovery of added calcium pantothenate from several substrates.

**Microbiological assay for pantothenic acid.** F. M. STRONG, R. E. FERNEX, and A. EARLE. (*Wis. Expt. Sta.*). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 8, pp. 566-570, figs. 2).—The method is based upon the fact that *Lactobacillus casei* (= *L. helveticus*), which requires riboflavin (*E. S. R.*, 82, p. 587), also requires pantothenic acid. With a basal medium complete for this organism except for pantothenic acid, the addition of crude suspensions of samples containing the acid stimulates fermentation. The amount of lactic acid produced, as determined by direct titration of the entire culture, is a measure of the pantothenic acid in the sample. In the method described as to cultures and inoculum, basal medium and procedure, assays of the sample under test are run at three levels estimated to fall within the range 0.03-0.12  $\mu$ g. of calcium pantothenate, and the titration results are compared with those from a standard curve established with pure *d*-calcium pantothenate. The pantothenate content of the sample calculated from the various levels must agree within at least 20 percent. The values for the three levels are averaged for the final results. Analyses of a number of products indicate that liver, yeast, kidney, egg yolk, dried whey, dried buttermilk, sweetpotato, and the bran of grains are all good sources; whole grains are much lower; and molasses is variable.

The reliability of the method is supported by agreement of the assay results at different levels, recovery of added pantothenic acid, absence of disturbing effects from other growth-promoting substances, comparison with results of chick assay on the same samples, and specificity of structure required for activity. The method is applicable to a wide range of materials, requires no expensive or unusual apparatus, and permits a single worker to assay about 15 samples per day.

**Polarographic determination of ascorbic acid.** M. M. KIRK. (*N. Y. State Expt. Sta.*). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 625-626, fig. 1).—This preliminary study of vitamin C, determined with a Fisher Elecdropode or polarograph, employed solutions of pure vitamin C in various buffers, of which 2 percent metaphosphoric acid was found to be the most satisfactory. The solution of the vitamin in the buffer was placed under the dropping mercury electrode and deaerated by bubbling nitrogen through it for 15 min. The determination was then carried out with the nitrogen streaming across the surface of the solution, and with the mercury dropping at the rate of 1 drop every 3-6 sec.

Curves obtained with the dropping mercury electrode polarized as the anode or as the cathode are presented and discussed. The results obtained indicated that the method could be adapted for accurate quantitative analysis by comparing the curves obtained with an unknown solution with calibration curves. The determination would be specific, sensitive to small amounts of ascorbic acid, and not hindered by the presence of pigments.

**Chemical methods for the determination of clinical vitamin C (ascorbic acid) deficiency**, G. J. KASTLIN, C. G. KING, C. R. SCHLESINGER, and J. W. MITCHELL (*Amer. Jour. Clin. Pathol.*, 10 (1940), No. 12, pp. 882-893).—The method adopted by the authors for evaluating the state of nutrition with respect to vitamin C consists in "(1) determining the fasting blood plasma level and urinary excretion, followed by (2) intravenous injection of 500 mg. of ascorbic acid, and (3) subsequent determination of the blood plasma value at 5 min. and both blood plasma and urinary excretion values after 1, 2, 3, and 4 hr." The typical normal blood saturation curve is characterized by a fasting level of 0.7 mg. of ascorbic acid per 100 cc. or higher, a relatively high (4.5-9 mg. percent) 5-min. level, and a gradual decrease to a point at 4 hr. still distinctly above the fasting level; the urinary excretion is highest in the first hour and amounts to 40 percent or more of the test dose during the 4-hr. period. The typical severe deficiency blood curve is characterized by a fasting level below 0.4 mg. per 100 cc. and only a slight and variable rise at 5 min., followed by a rapid fall to near the fasting level; the total urinary excretion ranges from a few milligrams to 20 percent of the test dose. The first responses to treatment of vitamin C deficiency are an increase in the 5-min. peak level and a decrease in the rate of fall of the blood concentration, together with an increase in total urinary excretion, these changes occurring before there is an appreciable rise in the fasting blood level.

Interpretation of the curves should be based on all factors of the test considered in connection with the dietary history and clinical condition. It is noted, however, that "the extreme instability of vitamin C in most foodstuffs may readily lead to deficiencies on dietary regimes that on paper appear to be adequate."

**Estimation of vitamin D in margarine**, N. T. GRIDGEMAN, H. LEES, and H. WILKINSON (*Analyst*, 65 (1940), No. 774, pp. 493-495).—It is pointed out that proposed chemical tests are inapplicable because of the low potency of margarines and the interference by other substances such as sterols, vitamin A, and carotenoids. Notes on the application of the line-test and bone-ash methods, as used by the authors for a number of years, are given, together with a brief discussion of their accuracy. Margarines of the potency of 1.0 International Unit of vitamin D per gram were assayed satisfactorily by the line-test method. Assays of vitamin concentrates and of margarines enriched with them showed that the margarine assay was not falsified by the feeding of fat to the test animals, except when necessarily large amounts were fed in the assay of very low-potency margarines. The more sensitive bone-ash method gave somewhat different results from the line-test method, possibly because the international standard was not so effective in the line-test as in the bone-ash assay.

**Modified technique for prothrombin determination in blood**, H. S. and R. W. HOLMBOE (*Jour. Lab. and Clin. Med.*, 26 (1940), No. 2, pp. 408-415, figs. 2).—The method described was developed after preliminary investigation of thromboplastin preparations from dried brain tissue from the rat, guinea pig, rabbit, sheep, and man, and after preliminary experiments showing the effect of varying the concentrations of thromboplastin, plasma, and calcium chloride. The method, based on that of Quick, employs 0.2 cc. of plasma from oxalated whole

blood (1 part 0.1 M sodium oxalate in 10 parts of oxalated blood), 0.2 cc. of thromboplastin solution representing an ether-soluble, acetone-insoluble extract of dried sheep brain diluted 1:5 with normal saline at the time of use, and 0.2 cc. of eightieth-molar calcium chloride solution. The mixture of plasma and thromboplastin solution in a serological tube is incubated at 37° C. for 7 min., and the calcium chloride then added immediately and mixed by shaking the tube, which is slanted and rotated at 15-sec. intervals. The interval between the addition of calcium chloride and clot formation, as measured by stop watch, constitutes the prothrombin time. The method applied to test samples of blood from 250 consecutive patients gave a range of prothrombin times from 55 to 85 sec., 92 percent of these cases coming within the range of from 60 to 80 sec. and averaging 70 sec.

**Utilization of California fruits**, W. V. CRUESS and G. L. MARSH (*California Sta. Cir. 349 (1941), pp. 53, figs. 11*).—This circular includes a brief general discussion of the present disposal of California fruits and considers such specific uses as unfermented beverages, fruit sirups for table use, fruit candies, pectin, bases for jellies and jams, frozen pack, fruits in ice creams and ices, dried-fruit products, fruits in cereal products, fruit sauces, sieved fruits or fruit purées, breakfast fruits, coffee substitutes, vinegar, pickled and spiced fruits, fruit wines, and fruit brandies. The value of fruits in the diet and the utilization of byproducts are also considered.

**Methods and equipment for the sun-drying of fruits**, E. M. MRAK and J. D. LONG (*California Sta. Cir. 350 (1941), pp. 69, figs. 26*).—This circular takes up fruits for drying, equipment (discussed in considerable detail), methods of preparation and drying, handling fruit after drying, farm-scale packing of dried fruits, storage and treatment of packed dried fruits, and routine analyses of dried fruits.

## AGRICULTURAL METEOROLOGY

**Dynamic meteorology**, B. HAURWITZ (*New York and London: McGraw-Hill Book Co., 1941, pp. X+365, figs. 89*).—The great recent progress in this field has been largely due to the application of the laws of thermodynamics and hydrodynamics to the study of the atmosphere and its motions. "It is the aim of this book to give an account of these investigations and their results, with regard to applications to weather forecasting and to research."

**Bibliographic tools for meteorological research**, R. W. BUEHNE (*Amer. Met. Soc. Bul., 22 (1941), No. 9, pp. 357-361*).

**La météorologie et l'agriculture [Meteorology and agriculture]**, L. BEAUGE (*Bonne Terre, 22 (1941), No. 5-6, pp. 129-146, pls. 4*).

**Preliminary studies in seasonal weather forecasting**, R. H. WEIGHTMAN (*Mo. Weather Rev. [U. S.] Sup. 45 (1941), pp. VIII+99, figs. 291*).—The purpose of this investigation, begun in 1931, was to make a preliminary survey, by means of simple correlation coefficients, of association between pressures at foreign stations and subsequent temperature and precipitation in the United States, with the idea that such a survey would point out the areas outside this country in which antecedent pressure conditions might be suggestive of time-lag relations with conditions in the United States. Though the study has produced no outstandingly large correlation coefficients, it is believed that this has been accomplished. The data are presented in 291 charts.

**Atlas of climatic types in the United States, 1900-1939**, C. W. THORNTWHAITE (*U. S. Dept. Agr., Misc. Pub. 421 (1941), pp. II+7, pls. 48, figs. 7*).—Few parts of the United States are free from the drought hazard. Although drought and flood years cannot be predicted, it is possible by using the many records of

the U. S. Weather Bureau to determine the frequency with which climatic events are likely to occur, and such information is of great aid in evaluating the agricultural potentialities of a region and in land-use planning. In this contribution (by the Soil Conservation Service in cooperation with the Weather Bureau) the evolution of the climatic pattern, vegetation as a climatic indicator, determination of effective precipitation, climates of the United States, and climatic variation are discussed (135 references), and the maps present graphically the moisture factor of climate and show the normal position of the principal climatic types, their variation from year to year, and the frequency of occurrence of the various individual climates. From a study of these maps, an appreciation of the diversity of the problems of soil and water conservation in the different parts of the country may be obtained.

**Special report on climatic conditions in the Dominican Republic, S. A. RORIOT V.** (*Ciudad Trujillo, Dominican Republic: Met. Serv., 1941, pp. 8, fig. 1; Span., pp. 5-8*).

**The uniform climate of Malaya as a barrier to plant migration, R. E. HOLTRUM** (6. *Pacific Sci. Cong., Calif., 1939, Proc., vol. 4, pp. 669-671*).—The author concludes that the climatic conditions are such as to form a barrier to the spontaneous dispersal of many plants adapted to a seasonal climate and needing the stimulus of a dry season to make them flower or a regular resting period in the rhythm of their vegetative and reproductive functions.

**Growth rings and climate, W. S. GLOCK** (*Bot. Rev., 7 (1941), No. 12, pp. 649-713*).—This monographic review (203 references) considers growth factors and their complexity, insects, cross-dating, statistical correlation, smoothing, cycles, samples as representative of growth increment, factors at a particular site, growth layers and annual increments, temperature correspondence, rainfall interval to which growth corresponds, correspondence of tree growth with rainfall, climatic changes and forest migration, growth patterns, and assumptions forming the groundwork for interpretation. It is concluded that "the derivation of climate from tree growth should be sought, apparently, by other means than by direct quantitative attempts to base amount of rainfall on width of growth layers although at times this, in a measure, can be done. Without doubt, 'the methods of an ecologically minded botanist' applied to tree growth through physiological function and its dependent anatomical response should supplant the more simple, the more obvious but less fruitful and less valid methods of direct correlations. An understanding of plant physiology and anatomy brought about by judicious experimentation under the strict discipline of the botanist may ultimately reveal the criteria by which growth layers and their cellular structure will yield a picture of the soil-moisture régime and perhaps thereby indirectly a picture of rainfall type."

**Mittelwellige UV.—Strahlung als Klimafaktor für Hochgebirgspflanzen [Ultraviolet radiation of medium wavelength as a climatic factor for alpine plants], K. PRSCHLE** (*Naturwissenschaften, 29 (1941), No. 11, pp. 165-166*).—A brief review of work by the author and others.

**Some effects of cold on plants in Alabama in 1940, R. M. HARPER** (*Torreya, 41 (1941), No. 5, pp. 166-169*).

**Surface runoff determination from rainfall without using coefficients (Amer. Soc. Civ. Engin. Proc., 67 (1941), Nos. 4, pt. 1, pp. 533-568, figs. 14; 6, pp. 1180-1182; 8, pt. 1, pp. 1469-1489, fig. 1; 10, pp. 1925-1932, figs. 5)**—In the main paper (pp. 533-568) W. W. Horner and S. W. Jens call attention to the recent improvement in hydrologic data with respect to precipitation and stream flow, and to the information with respect to infiltration developed from research by the U. S. Department of Agriculture. They outline a method of applying this

information for evaluating surface run-off from precipitation data without use of a coefficient which they deem generally applicable to all drainage basins and is as detailed as would be used in urban storm drainage.

Discussions of the paper follow by L. L. Harrold (pp. 1180-1182), C. E. Ramser, L. K. Sherman, A. J. Schafmayer, C. S. Jarvis, G. W. Musgrave, and F. L. Flint (pp. 1469-1488), and W. I. Hicks (pp. 1925-1932).

**A study of excessive rainfall**, H. D. DYCK and W. A. MATTICE (*Mo. Weather Rev.* [U. S.], 69 (1941), No. 10, pp. 293-301, figs. 17).—For statistical purposes the Weather Bureau classifies excessive rainfall into four groups, two for short-period storms giving the minimum rate of fall in terms of minutes for a group of southern States as distinguished from the rest of the United States and the other two being established at 1 in. in 1 hr. and 2.5 in. in 24 hr. Yarnell has covered excessive rains for short periods (*E. S. R.*, 74, p. 7). The two longer periods are taken up here, in a general way supplementing and extending Yarnell's material.

**Torrential rains as a serious handicap in the South**, S. S. VISHIE (*Geog. Rev.*, 31 (1941), No. 4, pp. 644-652, figs. 2).—Recently available evidence that soil erosion is especially serious in the southern United States invites attention to its climatic basis. Towards this end the present paper discusses, in addition to the general question, a special study of 24-hr. rains of more than 10 in., the causes of regional contrasts, and some effects of big rains.

**Rainfall conditions as a southern handicap**, S. S. VISHIE (*Jour. Geog.*, 40 (1941), No. 8, pp. 302-306).—The author discusses the undesirable seasonal distribution of rainfall, heavy cool season rainfall, thundershowers, and 24-hr. rains in excess of 10 in.

**Mountain floods and vegetation**, R. W. BAILEY (*6. Pacific Sci. Cong., Calif., 1939 Proc.*, vol. 4, pp. 731-736).—A general discussion is presented of the destructiveness of mountain floods to vegetation, the factors involved in the process, and control methods that may be employed, with examples in the Colorado-Utah-Arizona area. A geological-ecological approach in the analysis of floods is suggested as a useful procedure for both engineers and plant men who are charged with the responsibility of coping with flood problems. "While the record of gradational processes may not always be readily apparent, this approach should prove helpful wherever circumstances permit."

**The rainfall of Martinique**, J. E. FAIRCHILD (*Amer. Met. Soc. Bul.*, 22 (1941), No. 6, pp. 249-255, figs. 8).

**Monthly Weather Review, [September-October 1941]** (*Mo. Weather Rev.* [U. S.], 69 (1941), Nos. 9, pp. 257-291, pls. 11, figs. 9; 10, pp. 293-327, pls. 10, figs. 20).—In addition to meteorological, climatological, solar radiation, and sunspot data, these numbers contain an article noted above and the following contributions of agricultural interest:

No. 9.—Automatic Dust Sampling and Analyzing Instruments for Atmospheric Pollution Surveys, by W. F. Davidson and W. Master (pp. 257-260); and Tropical Disturbances of September 1941, by H. C. Sumner (pp. 264-266).

No. 10.—Hurricane of October 3-12 and Tropical Disturbance of October 18-21, 1941 [in the Bahama Islands-Florida Area], by H. C. Sumner (pp. 303-304).

## SOILS—FERTILIZERS

[Soil investigations at the Alabama Station] (*Alabama Sta. Rpt. 1940*, pp. 16-17, 18-20, fig. 1).—The value of contour furrows for water conservation on pasture land is reported by J. H. Neal, A. W. Cooper, and E. L. Mayton; differences in run-off and soil losses from terrace outlets on strip-cropped and

on clean-cultivated areas, by E. G. Diseker; a comparison of crimson clover and hairy vetch as soil-conserving crops, by Neal and C. H. Bailey; the limitation of soil tests for available potassium in soils, by N. J. Volk; a survey of the agricultural lime resources in Alabama, by J. A. Naftel; and a comparison of the relative values of superphosphate, rock phosphate, and colloidal phosphate for crop production, and the effect of ammonium sulfate on the availability of rock phosphate for crop production, both by G. W. Volk.

[Soil investigations of the Colorado Station] (*Colorado Sta. Rpt. 1941, pp. 11, 21-22*).—Progress on the following investigations is reported: Optimum nutrient balance in soils, availability of mineral nutrients, effects of irrigation water on soil, and methods of isolation and the distribution of the soil micro-organism *Azotobacter vinelandii* in Colorado.

[Soil Survey Reports, 1936 and 1937 Series] (*U. S. Dept. Agr., Bur. Plant Indus. [Soil Survey Rpts.], Ser. 1936, No. 9, pp. 59, figs. 2, map 1; 1937, No. 4, pp. 57, figs. 3, map 1*).—These surveys were made in cooperation with the Iowa Experiment Station and the University of Georgia, respectively: 1936, No. 9, Story County, Iowa, H. R. Meldrum et al.; and 1937, No. 4, Catoosa County, Ga., A. E. Taylor et al.

Distribution of carbon in morphological units from the B horizons of Solonetz-like soils, J. L. RETZER and R. W. SIMONSON. (*Iowa Expt. Sta. coop. U. S. D. A.*). (*Jour. Amer. Soc. Agron.*, 33 (1941), No. 11, pp. 1009-1013, figs. 3).—Results of investigations on the distribution of carbon within morphological units (columns) from the B horizons of Solonetzlike soils from California and Nevada are presented. The highest contents of carbon were found in the outermost layer on the faces of the columns, and the lowest amounts were found either in the core or the light-gray cap of the unit.

The influence of tree roots on soil morphology, H. J. LUTZ and F. S. GRISWOLD (*Amer. Jour. Sci.*, 237 (1939), No. 6, pp. 389-400, pl. 1, figs. 4).—The authors point out that tree roots may cause profound and diverse disturbances which may account for many of the morphological characteristics of soil profiles developed under forest stands.

The laws of soil colloidal behavior.—XXIII, The constitution of the pedosphere and soil classification, S. MATTSON (*Soil Sci.*, 51 (1941), No. 5, pp. 407-425, figs. 4).—In the twenty-third contribution of this series (E. S. R., 84, p. 155), the author proposes viewing the soil, its parts, and activities in accordance with a biological analogy in which the body as a whole is compared with the pedosphere, the anatomy with the great soil groups, the morphology with the soil type as based on profile characteristics, the histology with the textural units, the protoplasm with the colloidal complex, and the physiology with the soil solution. A classification is based on nine groups (humus content and base status), types and series (profile characteristics), varieties (texture), colloid-chemical factors (composition, amphoteric, and colloidal behavior of colloids), and physiological factors (pH and KPN status). The term "pedosphere," as above used, is so defined as to include the mineral, aqueous, atmospheric, and biological materials of the soil, which "alternate as dispersed phase and dispersion medium."

The soil-forming processes in relation to anionic and cationic solvation and eluviation are discussed.

A pressure-membrane extraction apparatus for soil solution, L. A. RICHARDS. (*U. S. D. A.*). (*Soil Sci.*, 51 (1941), No. 5, pp. 377-386, figs. 3).—In a modified form of suction apparatus, a carefully supported Cellophane membrane serves as the bottom of a gas-pressure chamber in which soils are placed for solution extraction. In this way the moisture content of soil in contact with

the membrane will be reduced by the amount that would be necessary under normal atmospheric conditions to make the pressure deficiency of the soil water equal to the excess gas pressure in the extration chamber. In each of 3 soils an extraction pressure of 16 atmospheres reduced the moisture content of from 5- to 10-mm. layers of soil from saturation to below the wilting point in from 24 to 36 hr. The apparatus can be used for obtaining sorption curves and studying the permeability of unsaturated porous media over a considerably extended range of negative pressure.

**A simple apparatus for measuring noncapillary porosity on an extensive scale,** R. W. LEAMER and B. SHAW. (Ohio Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 33 (1941), No. 11, pp. 1003-1008, fig. 1).—A simple, inexpensive apparatus for measuring "noncapillary" porosity on a large number of soil samples is described. The pressure-deficiency method of removing water from a saturated sample is the basis of the apparatus. The equipment accommodates 30 3-in. core samples, but the authors point out that there is no limit to the number that may be used.

**Field percolation rates of four Wisconsin soils having different drainage characteristics,** L. B. NELSON and R. J. MUCKENHORN. (Wis. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 33 (1941), No. 11, pp. 1028-1036, figs. 2).—Percolation rates as determined by a buffer-compartment method are given for undisturbed soil profiles of two poorly drained and two well-drained Wisconsin soils. Data on laboratory percolation rates, total porosities, volume weights, and maximum water-holding capacities are presented for soil cores taken from the different horizons of each of the four soils.

**Effect of crops and slopes on rates of run-off and total soil loss,** J. H. LILLARD. (Va. Expt. Sta. and U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 11, pp. 396-398, 406, figs. 9).—Run-off rates and amounts from corn, wheat, and hay crops grown on five different slopes on Dunmore silt loam are presented by means of hydrographs and maximum intensity curves. The author points out the difficulty of attempting to assign to any one factor its quantitative effect on the erosion process for any specific condition because these effects are constantly changing as a result of their interrelation with other factors. It is concluded, however, that a close-growing crop, such as wheat, will prevent excessive rates of run-off from Dunmore silt loam on slopes of 5, 10, 15, 20, and 25 percent under Virginia rainfall conditions. High rates of run-off are to be expected from corn grown on this soil, and serious losses will result when corn is planted on slopes above 10 percent.

**The four-electrode resistance method for measuring soil-moisture content under field conditions,** N. E. EDLEFSEN and A. B. C. ANDERSON. (Calif. Expt. Sta.). (*Soil Sci.*, 51 (1941), No. 5, pp. 367-376, figs. 6).—In order to eliminate the effect upon the results of the highly erratic contact resistance between electrode and soil, the four-electrode method was used in measuring the electrical resistance of the soil as a function of moisture content. Such measurements were made both in a Sudan grass and in a sugar beet plot. Tinned iron electrodes were found to be more sturdy and convenient than carbon and proved to be entirely satisfactory. A comparison of the resistances at the same moisture content before and after irrigation indicates that the variations in resistances due to factors other than moisture, under the conditions of this experiment, are not great in the top 4 ft. of soil.

There was no sudden increase in the electrical resistance of the soil as the plant continued to remove water in the vicinity of the permanent wilting percentage. When the electrical resistances of a soil supporting a crop are plotted as a function of moisture content, a curve is obtained showing a rapid

increase in resistance with decreasing moisture content in the neighborhood of the permanent wilting percentage. This curve appears to be asymptotic to the moisture content corresponding to the permanent wilting percentage.

**The avallameter and its use in soil moisture control.**—II, Calibration methods, R. B. ALLEN and R. A. WORK. (Oreg. Expt. Sta. coop. U. S. D. A.). (*Soil Sci.*, 51 (1941), No. 5, pp. 391-406, figs. 7).—Soil stability measurements made by means of an instrument described in the preceding paper (E. S. R., 85, p. 732) of this series were compared with oven-dry soil-moisture determinations over a wide range both of soils and of moisture content. The correlation curves thus obtained can be converted into terms of available soil moisture by the use of soil-moisture constants. A good correlation between avallameter soil-stability readings and available soil moisture is shown even where soil-moisture constants varied somewhat from location to location in small areas. A method whereby an approximate calibration may be quickly obtained from limited local data is also presented.

Comparisons of soil moisture as determined by oven-drying and by the avallameter showed close agreement. The difference was less than 2 percent of the available soil-moisture capacity in the great majority of cases on heavy clay soil. Comparisons in terms of total moisture content showed differences of less than 0.5 percent in most cases. Very little time additional to that required to obtain the field samples alone is needed to complete the moisture determinations by the avallameter method. The complete operation can be made directly in the field without technical skill or laboratory equipment.

**Método tonométrico simple para la determinación indirecta del coeficiente de marchitez del suelo** [A simple indirect method for determining the wilting coefficient of soils based on tonometric equilibrium], A. ABENA (*Rev. Argentina Agron.*, 8 (1941), No. 3, pp. 220-234, figs. 6; *Eng. abs.*, pp. 232-233).—The technic is described in detail. The author recommends the method because it is inexpensive and simple and allows for several determinations.

**Erodibility investigations on some soils of the upper Gila watershed**, J. E. FLETCHER and E. L. BEUTNER. (Coop. Ariz. Expt. Sta.). (*U. S. Dept. Agr., Tech. Bul.* 794 (1941), pp. 32, figs. 14).—From the data collected in the Department's surveys of the upper Gila watershed of Arizona and New Mexico, curves have been made by plotting mean percent erosion against slope. From these curves erodibility has been defined and a numerical value, erodibility integral, has been employed to express it. An analysis of these erodibility-integral values indicated that soil erodibility varies with the parent rock. In the southern Gray Desert soils, the order from the erodible to the nonerodible soil-producing parent rock is (1) limestone, (2) mixed origin, (3) granite, (4) rhyolite and basalt, and (5) quartzite; and in the southern Brown soils, (1) granite, (2) rhyolite, and (3) quartzite, limestone, and basalt. The data also indicated that erodibility varies with size of rock particles, rocky soils proving more erodible than gravelly soils within any one soil type. Erodibility increases as the texture within a series becomes coarser. The characteristics of four soils of the upper Gila watershed are described in some detail following fairly complete analyses.

**Effect of mulching materials on moisture loss from soils**, L. M. TURK and N. L. PARTRIDGE. (Mich. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 59-62).—Shallow-lysimeter data are presented. Although the relative amount of water collected during four periods varied somewhat between the different series, the lysimeters with no mulch and those with peat mulch gave small amounts of drainage water, and the lysimeters under other mulching materials (gravel, sawdust, shavings, straw, alfalfa hay, and stover) gave considerably

larger quantities of percolate during the same time. These more effective materials differed only slightly, and their effectiveness in water conservation appeared to be in the order in which they are listed, gravel most effective and stover least.

**The Missouri soil saving dam: Low-cost structure for use in farm plans for water management**, J. C. WOOLEY, W. M. CLARK, and R. P. BEASTLEY (*Missouri Sta. Bul.* 434 (1941), pp. 23, fig. 11).—The dam is constructed on a slope between 1.25:1 and 1.5:1, and thus utilizes the angle of repose of the soil to avoid the necessity of heavy construction. The cut-off wings are also constructed on a slope extending back into the berm, allowing the earth to lie on the sloping wing and avoiding, to a large degree, the tendency of earth to pull away from the structures in dry weather, as from a vertical wall structure. Effects of shrinkage or freezing of the soil are minimized. The new structure is not anchored deeply in the ground, where its parts would be subjected to different conditions and thus to varying stresses. The structure also consists of a combination of arches, avoiding excessive stresses encountered in straight-wall and corner construction. Wood forms, except for the velocity check, are not needed. Earth forms are produced by cutting or building. The reinforcing mesh is pulled or blocked up 2 in. above the earth, and concrete is floated (by means of a wood float) to a uniform thickness of 4 in. When it begins to set it is worked with a steel trowel to leave a dense weather-resistant finish. Working drawings are included. The proper use and placement of such dams are discussed.

**Early American soil conservationists**, A. McDONALD (*U. S. Dept. Agr., Misc. Pub.* 449 (1941), pp. [1]+63, pl. 1, figs. 8).—This is a historical review of the work and writings of Jared Eliot, Samuel Deane, Solomon Drown, John Taylor, John Lorain, Isaac Hill, Nicholas Sorsby, and Edmund Ruffin. These outstanding conservationists directed the farmers' attention to the dangers of erosion in this country and correctly analyzed its social, economic, and physical causes. Methods of control in relation to slope, soil type, and climatic differences were worked out for various parts of the country. The early conservationists also brought out the danger of exploiting the land by growing cash crops and of the importance of Government cooperation in bringing about soil conservation.

**Nonsymbiotic nitrogen fixation in soils of a semi-arid region of north China**, R. T. MOYER (*Jour. Amer. Soc. Agron.*, 33 (1941), No. 11, pp. 980-993).—A soil from a semiarid region of north China was investigated to determine the extent of nitrogen addition through nonsymbiotic nitrogen fixation. The total nitrogen content of a soil over a period of years of cropping determined from small artificial crops showed that the soil underwent a marked loss of nitrogen, and the amount lost was approximately the same as the nitrogen removed in the harvested crops. Soil was placed in large pots sunk in the ground in an attempt to measure the amount of nitrogen added to the soil by fixation. In one of the experiments it was not found possible to account for the loss of nitrogen which occurred. In no case was there found to be a gain in nitrogen from fixation. In comparing Honeoye silt loam and Dunkirk silty clay loam with the China soil, it was found that a greater number of macroscopic colonies of *Acetobacter* appeared on the former soils but that nitrogen was fixed at a more rapid rate by the China soil. The author concludes that the amount of nitrogen added by nonsymbiotic fixation is not sufficient to provide a very great part of that required by the growing crop.

**Studies on nitrate and ammonia in soils under permanent pasture.—I, The stabilization of nitrate in soil samples**, E. B. DAVIES, M. R. COUP, F. B.

THOMPSON, and R. P. HANSEN (*New Zeal. Jour. Sci. and Technol.*, 21 (1940), No. 6A, pp. 348A-351A).—The value of toluene and of cooling as means of stabilizing nitrate in soil samples has been determined. Three drops of toluene per 500 gm. of soil was found to be sufficiently effective. A slight decrease in nitrate was apparent at the end of 2 days, but by the end of a week a rising tendency was found. Larger amounts of toluene reduced the concentration of nitrate in soils. Cooling below the freezing point failed to prevent nitrification in 0- to 1-in. samples but was effective in 1- to 3-in. samples.

**The behavior of soluble organic phosphates added to soils**, L. A. PINCK, M. S. SHERMAN, and F. E. ALLISON. (U. S. D. A.). (*Soil Sci.*, 51 (1941), No. 5, pp. 351-365, figs. 4).—In general, the phosphorus in sodium glycerophosphate, calcium hexosediphosphate, sodium nucleate, dipotassium phenyl phosphate, and disodium ethyl phosphate was retained rapidly by Cecil clay loam and usually by Las Vegas loam, whereas retention by Norfolk sandy loam was not so rapid or so complete. The phosphorus in potassium diphenyl phosphate and in potassium diphenyl pyrophosphate usually remained, water-soluble for a considerably longer period. The un-ionized triethyl and trimethyl phosphates could be completely recovered from two of the three soils after 3 weeks. Phosphorus supplied as calcium diethyl phosphate tended to remain in the water-soluble form for several days, and might possibly have some advantages over inorganic phosphates from the standpoint of penetration. Some of the organic phosphates, such as glycerophosphate, were retained by heavy soils so tenaciously and so quickly after addition as to indicate that colloidal action rather than micro-organisms must have been the primary process.

**Comparative availabilities of organic and inorganic phosphates as shown by the Neubauer method**, F. E. ALLISON, L. A. PINCK, and M. S. SHERMAN. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 33 (1941), No. 10, pp. 918-926, fig. 1).—The availability or toxicity of several organic and inorganic phosphate materials is reported. The organic carriers included glycerophosphate, hexosediphosphate, nucleic acid and its sodium salt, monophenyl and diphenyl orthophosphates, diphenyl pyrophosphate, and monoethyl, diethyl, and triethyl phosphates, while the inorganic phosphates used for comparative purposes were mono-, di-, and tricalcium phosphates, hydroxyapatite, calcined phosphate, and sodium metaphosphate. All of the organic phosphates, with the exception of triethyl phosphate, showed availabilities similar to those of the common inorganic phosphates. Triethyl phosphate, which does not hydrolyze in aqueous solution, showed a negligible availability as a plant nutrient. The phenyl phosphates, particularly the monophenyl phosphate, were toxic in the lighter soils and at the higher concentration.

The authors point out that the results as a whole emphasize the importance of the soil itself in determining the ability of plants to utilize added organic and inorganic phosphates. The results noted above are reviewed to bring out the fact that organic phosphates are fairly rapidly converted into inorganic phosphates, thus making their behavior in plant-nutrition studies not markedly different from that in inorganic phosphates. With both the organic and inorganic phosphates a high colloidal or clay content, especially if iron and aluminum oxides are abundant, leads to marked phosphate fixation.

**Arsenic in natural phosphates and phosphate fertilizers**, T. H. TREMEARNE and K. D. JACOB (*U. S. Dept. Agr., Tech. Bul.* 781 (1941), pp. 40).—Of 162 samples of various types and grades of domestic mineral phosphates the content of acid-soluble arsenic ranged from 0.4 p. p. m. in a Florida soft phosphate to 188.2 p. p. m. in an Arkansas phosphate. The average results were in the descending order, South Carolina river rock 68.4 p. p. m., Arkansas 61, Mon-

tana 47.6, Tennessee blue rock 20.4, Utah 17.8, Oklahoma 17.6, South Carolina land rock 17.1, Tennessee brown rock and phosphatic limestone 14.6, Idaho 12.6, Wyoming 12.1, Florida land pebble 11.9, Tennessee white rock 10.6, Kentucky 9.9, Florida waste pond 9, Florida soil 7.5, Virginia fluorapatite 5.5, and Florida hard rock 5.4 p. p. m. The results for arsenic in 48 samples of mineral phosphates from Africa, Canada, Europe, South Australia, and various islands ranged from 5.1 p. p. m. in calcium phosphate from Nauru Islands to 76.2 p. p. m. in aluminum iron phosphate from Daito Islands.

It is shown that arsenic occurred in phosphate rock principally, if not entirely, in the acid-soluble condition, and that the presence of fluorine compounds in the rock caused serious error in its determination unless arsenic-free glassware is used for the acid digestion.

"There is, in general, no orderly relationship between the arsenic content and the geologic age of phosphate rock or between the arsenic content and the quantities of other constituents (phosphorus, iron, sulfide sulfur, organic carbon, or nitrogen). . . . There is evidence that phosphates from primary deposits tend to contain somewhat more arsenic than do those from secondary deposits. The arsenic content of mineral phosphates is similar, in general, to that of marls, domestic shales, carbonate minerals, coals, and silicate rocks and minerals; usually it is higher than that of soils, clays, sediments, and nitrate and halide minerals, but is much lower than that of oxide minerals, greensand, glauconite, and especially sulfide materials."

The results for arsenic in 30 samples of ordinary and double superphosphates, made from Florida, Tennessee, Idaho, and Montana phosphate rocks, ranged from 2.2 p. p. m. in an ordinary superphosphate made with sulfuric acid obtained as a byproduct of a zinc-smelting operation to 1,199.1 p. p. m. in an ordinary superphosphate made with a mixed acid produced from domestic sulfur and Spanish pyrite. Ordinary superphosphates made with sulfuric acid produced entirely from domestic sulfur or obtained as a byproduct of a copper-smelting operation in Tennessee contained less than 15 p. m. m. of arsenic. In the double superphosphates (11 samples) the results for arsenic ranged from 11.1 p. p. m. in a material made from Tennessee brown-rock phosphate with phosphoric acid produced by the electric-furnace process to 404.6 p. p. m. in a material made from Idaho phosphate rock with phosphoric acid produced by the wet process, using sulfuric acid made from an iron sulfide concentrate.

"In proportion to their phosphorus contents, calcined, sintered, or nodulized phosphates usually contain notably less arsenic than do the parent phosphate rocks. Only a small portion of the arsenic in the parent phosphate rock is retained in defluorinated phosphate. . . .

"Arsenic was found in ammonium phosphate (5.5 to 74.2 p. p. m.), basic slag (2.1 to 11.2 p. p. m.), and bone ash and bonemeal (0.2 to 2.2 p. p. m.). Calcium metaphosphate, fossil bone and teeth, dicalcium phosphate, flue dust from a phosphoric acid blast furnace, Non-Acid phosphate, and Peruvian guano contained arsenic in quantities ranging from 2.6 in the first material to 24.9 p. p. m. in the last.

"When all the factors affecting the action of arsenic on plants and on soil organisms under practical conditions of farming are taken into consideration, it seems very unlikely that the quantities of arsenic contributed to the soil in phosphate fertilizers are sufficient to produce toxic effects even with very large annual applications of the fertilizer over extended periods of time."

**A nutrient element slighted in agricultural research, F. J. ALWAY.** (Minn. Expt. Sta.). (*Com. Fert.*, 62 (1941), No. 4, pp. 12-19).—An address setting forth the history of research on and the present status of knowledge of sulfur as a plant nutrient.

**Available boron as affected by soil treatments, G. R. MUHR.** (Mich. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 220-226).—Calcium and magnesium carbonates applied to Warsaw sandy loam and Hillsdale sandy loam B horizon soil, both acid soils, reduced the boron content of soybean tissue. Sodium carbonate and sulfate did not alter the boron content of soybeans on these soils. Calcium and magnesium sulfates did not alter the boron content of the tissue of soybeans grown on the Hillsdale soil not treated with borax, but reduced the boron content of those grown in pots to which excessive borax had been applied. Accumulations of calcium and nitrogen accompanied an excessive boron content in the plant tissue. Active calcium, organic matter, and clay, which prevented applied borax from becoming toxic to soybeans, prevented boron from accumulating in the plant tissue. Yields were increased with applications of borax until the boron content of the dry plant tissue reached 30 p. p. m. Borax became toxic to soybeans when the boron content of the dry tissue reached from 50 to 60 p. p. m. The magnesium and iron contents of soybeans were not greatly altered by toxic quantities of borax. When sugar beets were grown in an alkaline soil, deficient in available boron, and were treated with borax and sulfur singly and in combination, sulfur sufficient to lower the pH from 7.5 to 6.2 was as efficient as borax in preventing heart rot. It was found that fixation of boron in an alkaline sandy soil, high in organic matter, was a rather slow process, as indicated by a reduction in the toxic effect of boron on soybeans when planting was delayed 2 mo. after the borax was applied.

**The effect of borax on the yield, appearance, and mineral composition of spinach and sugar beets, R. L. COOK and C. E. MILLAR.** (Mich. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 227-234, figs. 3; *abs. in Michigan Sta. Quart. Bul.*, 24 (1941), No. 2, pp. 150-151).—Borax, applied at the rate of 20 lb. per acre as a side dressing for sugar beets on Wisner silt loam, very nearly eliminated heart rot symptoms, increased the yield from 7.16 to 14.3 tons per acre, and the sucrose content and purity from 14.11 to 18.02 percent and from 80.92 to 84.91 percent, respectively. Applied broadcast for spinach at the rate of 10 lb. per acre, borax prevented the appearance of boron-deficiency symptoms and caused the yield to increase from 8.1 to 14.3 lb. per plat. On the plats which did not receive borax, the spinach plants developed symptoms almost identical with symptoms of heart rot in sugar beets. Borax increased the boron content of the dry tissue of sugar beet roots and of spinach roots and tops and reduced the nitrogen content of sugar beet and spinach roots. Ammonium nitrate, applied to pot cultures of Thomas sandy loam, decreased the boron content of sugar beet roots. Applications of borax decreased the percentage of iron in sugar beet roots and spinach tops. In one pot-culture experiment, borax increased the percentage of magnesium in sugar beet roots. It had no effect on the calcium content of either sugar beets or spinach.

**A case of cobalt deficiency on limestone soil, K. J. McNAUGHT and G. W. PAUL** (*New Zeal. Jour. Sci. and Technol.*, 21 (1940), No. 6A, pp. 343A-344A).—A highly calcareous soil in the Wairarapa was observed to have caused a localized case of cobalt deficiency affecting both cattle and sheep. Analyses of the soil and pastures showed a low cobalt content. The deficiency condition was overcome through the use of cobaltized salt lick.

**Soil and plant tests as aids in soil fertility programs, J. B. HESTER** (*Year-book Com. Fert.*, 1941, pp. 31-39, figs. 12; also in *Com. Fert.*, 63 (1941), No. 5, pp. 10-16, 18, 20, figs. 12).—The author presents a general discussion of plant nutrients in the soil and various factors that affect their availability to the plant.

Important information on these factors can be obtained through soil and plant analyses. The use of these various tools are particularly valuable in bringing about more economical production. The author suggests a working basis for minimum and maximum amounts of nitrogen, phosphorus, and potash based on plant tissue and soil tests.

**Inspection of commercial fertilizers, II.** R. KRAYBILL ET AL. (*Indiana Sta. Cir. 265 (1941), pp. 89, fig. 1*).—Statistics of fertilizers sold in Indiana in accordance with the Indiana fertilizer law are presented, together with the usual analyses.

**Commercial fertilizers, 1941.** E. R. TOBEY (*Maine Sta. Off. Insp. 181 (1941), pp. 63-109*).—The analyses of samples of fertilizers collected and submitted during the 1941 season to the station, in accordance with the provisions of the fertilizer law (E. S. R., 84, p. 740), are presented.

**Inspection of commercial fertilizers and agricultural lime products for the season of 1941.** P. H. SMITH ET AL. (*Massachusetts Sta. Control Ser. Bul. 109 (1941), pp. 55*).—Detailed analytical and statistical data pertaining to the Massachusetts Fertilizer Control Service on mixed and unmixed fertilizers and on liming materials are summarized for the 1941 season (E. S. R., 84, p. 740).

**Commercial fertilizers in 1940-41.** G. S. FRAPS, T. L. OGIER, and S. E. ASBURY (*Texas Sta. Bul. 607 (1941), pp. 47*).—This is the usual annual presentation of data regarding fertilizers sold in Texas as required by the fertilizer control law. In addition to analyses, general information is given about fertilizers, as well as discussions on the subjects of vitamin B<sub>1</sub> and water culture.

## AGRICULTURAL BOTANY

**Plant science section** (*Jour. Colo.-Wyo. Acad. Sci., 2 (1940), No. 6, pp. 35-38; 3 (1941), No. 1, pp. 33-39*).—The following abstracts of papers are of interest to agricultural botany:

**Vol. 2, No. 6.**—Persistence of Impermeability in Alfalfa Seeds, by A. M. Lute (p. 35), and Some Histological Studies of Winter Injured Raspberry Canes, by A. G. Simonds (p. 35) (both Colo. State Col.).

**Vol. 3, No. 1.**—*Trifolium fragiferum* L.—A New Immigrant Clover to North America, by J. Ewan and A. Vaughan (p. 33); Further Notes on *Suckleja* in Colorado, by F. A. Riedel (p. 34); A Natural Occurring Root Graft in Sugar Beet, by A. O. Simonds (p. 36), and Observations on the Mycorrhizal Fungi and Mycorrhizae of Four Coniferous Plantations in the Rhine Valley (p. 37) and A Survey of Northern Colorado Flora Bearing Mycorrhizae (p. 37), both by W. D. Thomas, Jr. (all Colo. State Col.); and The Effects of Some Natural Gases Upon Plants, by W. G. Solheim and R. W. Ames (p. 38) (Univ. Wyo.).

**Indications of an increase in number of C-atoms in acids and number of acids in seed fats with advance in evolutionary position,** J. B. MCNAB (*Science, 94 (1941), No. 2444, p. 422*).

**Wayside trees of Malaya, I, II.** E. J. H. CORNER (*Singapore: Govt., 1940, vols. 1, pp. VII+770, figs. 259; 2, p. [1], pls. 228*).—Volume 1 contains the text and text figures and volume 2 the plates.

**Exploraciones micologicas de la America tropical: Un ejemplo de cooperacion inter-americana** [Mycological explorations in tropical America: An example of inter-American cooperation], C. E. CHARDON (*Bol. Soc. Venez. Cien. Nat., 6 (1940), No. 45, pp. 218-237*).—This is a review (51 references) of work in Puerto Rico, Dominican Republic, Colombia, Venezuela, and Brazil, and of various fungus groups, with an evaluation of the results obtained.

**Contribución a la bibliografía botánica Argentina, I** (Contribution to the botanical bibliography of Argentina, I), A. CASTELLANOS and R. A. PÉREZ-MOREAU (*Lilloa*, 6 (1941), No. 1, pp. 5-161; *Eng. abs.*, p. 5).—This is a bibliography of the species of vascular plants of Argentina from Linnaeus' time through 1937, and part 1 includes general works and the Pteridophyta, Gymnospermae, and Monocotyledoneae.

**Algunos datos sobre el maíz en Venezuela: Distribucion de las variedades botánicas** [Data on corn in Venezuela: Distribution of botanical varieties], B. SCHELOTTO and A. H. MARCHIONI (*Rev. Argentina Agron.*, 8 (1941), No. 1, pp. 49-56, *figs.* 2; *Eng. abs.*, p. 56).—The authors made a survey (with map of distribution) of the botanical varieties and pigmentation of corn, studying 113 samples and finding the following percentages; *Zea mays indentata* 64, *Z. mays indurata* 18, *Z. mays amylacea* 11, and *Z. mays everta* 7. The colors were 63 percent white, 31 yellow, 3.5 red, and 2.5 percent purple.

**The geography of the endemic potatoes of South America**, S. M. BUKASOV (*Rev. Argentina Agron.*, 8 (1941), No. 2, pp. 83-104).—The wild species are taken up under the Atlantic coast, Pacific coast, and Andean groups, and the groups of the cultivated Andean species are also considered.

**Algunos datos sobre el barbasco** [Some data on barbasco], L. WILLIAMS (*Bot. Soc. Venez. Cien. Nat.*, 6 (1939), No. 41, pp. 21-33).—A discussion of the plants from which the so-called fish poisons (including derris and rotenone) are obtained, with special reference to their presence, composition, production, and exploitation in Venezuela.

**Plant physiology**, M. THOMAS (*London: J. & A. Churchill*, 1940, 2. ed., pp. XII+596, *figs.* 61).—This is the second edition of a book previously noted (*E. S. R.*, 74, p. 610).

**Shock anesthesia in Myxomycetes**, W. SEIFRIZ and N. EPSTEIN (*Biodynamica*, 3 (1941), No. 67, pp. 191-197).—When a plasmodium was hit by a falling drop of water or by the stroke of a needle, protoplasmic flow suddenly stopped. This is regarded as a case of anesthesia. The shock anesthesia was accompanied by a thixotropic setting or sudden gelatinization of the protoplasm. Recovery was complete if the cessation of movement from the shock was not accompanied by traumatic injury.

**Mechanism of symbiotic nitrogen fixation**.—V, Nature of inhibition by hydrogen, P. W. WILSON, S. B. LEE, and O. WYSS. (*Univ. Wis.*). (*Jour. Biol. Chem.*, 139 (1941), No. 1, pp. 91-101, *figs.* 4).—In this number of the series (*E. S. R.*, 80, p. 741), two methods determining the mode of action of an inhibitor for an enzyme reaction (whether competitive or noncompetitive) are illustrated by experiments in which H<sub>2</sub> acts as a specific inhibitor for symbiotic N fixation in red clover. The methods are based on plotting certain functions of the rates of reaction against (1) concentration of inhibitor for two or more concentrations of substrate, and (2) reciprocal of concentration of substrate for two or more concentrations of the inhibitor. Straight lines are obtained whose slopes are tested for significant differences by appropriate statistical procedures. Results from seven experiments, five of which are here described, consistently favored the view that inhibition of the symbiotic N fixation reaction by H<sub>2</sub> is competitive.

**The relation of varieties of the soybean to various strains of the Rhizobia**, T. PUNYASINGHA (*Thai Sci. Bul.*, 3 (1941), No. 1, pp. 11-27).—The host origin of a *Rhizobium* strain influenced its activity. Some cultures seemed to be more efficient in inoculating one variety than others, but no single culture produced the best inoculation on all 44 soybean varieties tested. While some cultures were consistently good in all of the tests, others proved very inefficient for

soybean inoculation. Indications that certain definite strains of soybean bacteria are required to produce the most efficient degree of nodulation on a given variety were obtained. There are 26 references.

**Failure of barley to fix molecular  $N^{15}$** , R. H. BURRIS (*Science*, 94 (1941), No. 2436, pp. 238-239).—The data presented indicate that if either barley or bacteria-free red clover plants fixed any N, the amount fixed was within the experimental error, whereas fixation by inoculated clover resulted in the accumulation of large amounts of the stable N isotope,  $N^{15}$ . These results, in relation to work by others, are discussed.

**Über die Abhängigkeit der Katalaseaktivität der Leguminosen von der Beschaffenheit des Impfmateri als** [The relationship of catalase activity in legumes to the nature of the inoculum], M. KRONBERGER (*Prakt. Bl. Pflanzenbau u. Pflanzenschutz*, 18 (1940), No. 7-8, pp. 126-130).—It is shown that inoculation with virulent nodule bacteria increased the catalase activity of legumes, and that this increase was directly correlated with the relative virulence of the bacteria.

**On the so-called "iodide oxidase" mechanism of iodide oxidation by *Aspergillus***, A. A. PEARCE (*Biochem. Jour.*, 34 (1940), No. 10-11, pp. 1493-1500, figs. 5).—The culture medium of *A. niger* oxidizes iodide to free I. This oxidation is not, however, catalyzed by a specific iodide oxidase or by an oxygenase as has been suggested by previous workers, but by  $H_2O_2$  formed in the medium. This  $H_2O_2$  is formed as a result of a primary oxidation reaction of glucose catalyzed by glucose oxidase. The oxidation of iodide is therefore a secondary oxidation reaction which can be promoted by every oxidizing system that reduces molecular  $O_2$  to  $H_2O_2$ .

**Growth-promoting and growth-inhibiting substances in the petiole** [trans. title], Y. OKABE (*Bot. Mag. [Tokyo]*, 54 (1940), No. 645, pp. 357-365, fig. 1; *Jap. text; Eng. abs.*, p. 365).—The growth-promoting and -inhibiting substances diffusing from the petiole segments of *Morus alba* into agar blocks were demonstrated by the oats coleoptile method, negative curvatures being induced in young and positive curvatures in mature leaves. Similar results were found in *M. bombycis*, *Cudrania triloba*, *Ficus carica*, *Thea sinensis*, *Salix viminalis*, and *Ginkgo biloba*. Negative and positive curvatures reached their maxima 2 and 3 hr., respectively, after application of the agar. It appears that the growth-promoting substance moves basipetally in the petioles but that the growth-inhibiting substance has no polarity of movement. If the leaf blades are removed, the growth-promoting substance in the petioles appears to go on decreasing, whereas the growth-inhibiting substance continues to increase until the petiole falls.

**On the distribution of growth-promoting and growth-inhibiting substances in *Morus alba* L. and *Cassia occidentalis* L.** [trans. title], Y. OKABE (*Bot. Mag. [Tokyo]*, 54 (1940), No. 647, pp. 453-461; *Jap. text; Eng. abs.*, p. 461).—The distribution of growth-promoting and -inhibiting substances diffusing from the stem and root of *M. alba* and *C. occidentalis* was studied by the oats coleoptile method, the agar blocks being applied (1) on the lower and (2) on the upper sides. Negative curvatures were induced by growth-promoting substance from the upper part of the stem in (1), whereas positive curvatures were caused by the substances from the middle and basal parts of the stem. Positive curvature was caused by (2) and negative by (1) from the upper part of the stem. Evidently, the growth-inhibiting substance is masked by the growth-promoting substance, especially in the upper part of the stem.

**Factors in coconut milk essential for growth and development of very young *Datura* embryos**, J. VAN OVERBEEK, M. E. CONKLIN, and R. F. BLAKESLEE (*Science*, 94 (1941), No. 2441, pp. 350-351).—"The success of coconut milk in fur-

nishing some accessory substances which stimulate the growth of isolated embryos in vitro suggests its applicability to other species and prompts this preliminary report."

**Vitamin B<sub>6</sub> and growth of excised tomato roots in agar culture, D. DAY** (*Science*, 94 (1941), No. 2446, pp. 468-469).—Pyridoxine was of distinct benefit to root growth. Neither glutamic acid nor glycine in the amounts used appeared able to replace it.

**Agencies affecting the production of substance B by *Rhizopus suinus*, C. L. WORLEY.** (Univ. Ga.). (*Plant Physiol.*, 16 (1941), No. 3, pp. 461-480, figs. 2).—A survey of all tests run (methods described) in this study indicated a lack of correlation between the amount of growth substance produced (i. e., total effectiveness) and the amount of *R. suinus* mycelia contributing to its production, but certain tests did indicate a relationship of substance B production with type of growth. There was no relationship between the areas exposed per unit volume and the effectiveness of the respective fungus filtrates, and, for reasons discussed, it is believed that the constant effectiveness of these filtrates indicates a lack of change in the balance between stimulators and inhibitors. White light exerted little or no effect, but yellow light reduced greatly the effectiveness of the *Rhizopus* filtrate and green lights had the opposite effect. Doubling the inoculum resulted in a significant increase in effectiveness of the ultimate filtrate. Changes in temperature had the most marked effect of any agent tried. One set of tests showed production of substance B to be directly related to the degree of aeration, and another tested the effects of filter paper on growth substance accumulation.

**Biotin and the growth of *Fusarium avenaceum*, W. J. ROBBINS and R. MA** (*Bul. Torrey Bot. Club*, 68 (1941), No. 7, pp. 446-462, figs. 6).—A strain of *F. avenaceum* failed to grow in a mineral-sugar solution but grew in the same solution solidified with agar, this beneficial effect being primarily due to biotin. Some agar samples contained as much as 0.1  $\mu$ g. of biotin per gram. This fungus strain was favorably affected by 0.001  $\mu$ g. of pure biotin methyl ester, but greater effects were obtained with larger amounts of biotin. Agar extract had a greater beneficial effect than could be accounted for by its biotin content. This may result from unidentified growth substances, which are believed not to be pyridoxine, pantothenic acid, thiamin, nicotinamide, *p*-aminobenzoic acid, pimelic acid, *t*-inositol riboflavin, glutamine, vitamin K<sub>1</sub>, or ascorbic acid. Mutations which grew on a biotin-deficient medium were observed.

***p*-Aminobenzoic acid, an essential metabolite for autotrophic organisms, S. WIEDLING** (*Science*, 94 (1941), No. 2443, p. 389).—The work was done on the diatom, *Nitzschia palea debilis*.

**Significant rôles of trace elements in the nutrition of plants, J. W. SHIVE.** (N. J. Expt. Stas.). (*Plant Physiol.*, 16 (1941), No. 3, pp. 435-445).—As a result of this analytical review (13 references) and the studies presented, it is pointed out that the rôles which may have been ascribed to B, Fe, and Mn, important as they may be, are mere incidents in the whole complex maze of physiological functions which they may indirectly assume in the vital activities of any species. Though it is impossible at present to assign any one particular process as the special function of a given trace element, it is probably safe to say that each of these elements is a critical factor in every important physiological process involved in the nutrition of the plant.

**Bor und Gramineen [Boron and Gramineae], W. SCHROFF** (*Forschungs-dienst*, 10 (1940), No. 2, pp. 138-160, pls. 4).—This is a general review (72 references) of the nutritive relations of boron to plants, with special reference to the small grains, corn, and grasses.

**The comparative boron content of potato leaves and tubers produced under different cultural conditions, R. MACVICAR, W. E. TOTTINGHAM, and**

G. H. RIEMAN. (Wis. Expt. Sta.). (*Amer. Potato Jour.*, 18 (1941), No. 9, pp. 249-253).—Analyses of tubers without corresponding leaf and stem samples gave little pertinent information as to total ash content or status of B nutrition of the plant as a whole. B analyses of several potato varieties grown in three regions of Wisconsin under similar culture treatment indicated the following ranges and averages in micrograms per gram of dry tissue for different plant parts: Leaf 20.9-73.8, 38.9; stem 19.0-66.6, 32.2; and tuber 5.5-13.9, 9.2.

Effects of pH and the components of bicarbonate and phosphate buffered solutions on the metabolism of potato discs and their ability to absorb ions, F. C. STEWARD and C. PRESTON (*Plant Physiol.*, 16 (1941), No. 3, pp. 481-519, figs. 9).—The effect of pH and the concentration of a  $\text{KHCO}_3/\text{H}_2\text{CO}_3$  buffer on absorption of bromide and metabolism of potato disks was investigated, using thin disks in aerated solutions at 23° C. Throughout, the effects of these treatments on the uptake of bromide, on protein synthesis, and on oxidations in the tissue catalyzed by oxidases (phenolase) were closely parallel. At constant pH, increasing the external concentration of  $\text{KHCO}_3$  and dissolved  $\text{CO}_2$  depressed both protein synthesis and bromide accumulation. Indirect evidence indicated that the bicarbonate solutions which retarded bromide absorption and protein synthesis also depressed respiration and carbohydrate metabolism. The similarity in the effects of these variables on both respiration and N metabolism was shown by comparing figures which indicate simultaneously the variation of the property in question (respiration, protein synthesis, or loss of soluble N) in relation to two variables (pH and phosphate concentration). Phosphates seemed to influence metabolism of potato disks through their effect on N metabolism (protein synthesis and use of amino acids), i. e., processes which appear remote from the accepted role of hexose phosphates in carbohydrate break-down. Respiration, protein synthesis, and bromide absorption are again seen to be closely linked. They are similarly affected by external variables, the effect of which on the tissue is consistently shown by reactions stimulated by the oxidase (phenolase) it contains. There are 27 references.

Accumulation of arsenic in the shoots of Sudan grass and bush bean, L. MACHLIS. (Hawaii Expt. Sta.). (*Plant Physiol.*, 16 (1941), No. 3, pp. 521-544, figs. 6).—When Sudan grass and bush beans were grown for different periods in various concentrations of sodium arsenite, it was found that As concentrations up to 0.5-0.6 p. p. m. had no effect on growth as measured by dry weight, but growth was suppressed at 1.2 and 12 p. p. m. of As for bean and Sudan grass, respectively. Additions of As to the solutions caused an immediate plasmolysis of the roots and wilting of the leaves, followed by discoloration of the roots and necrosis of leaf tips and margins, indicating that the As caused a sudden decrease in water movement into the plants. The As concentrations in plant tops and in each of the other parts except the reproductive structures were proportional to the concentrations in the nutrient solutions. The magnitudes of these concentrations were more or less constant during the experimental periods (up to 9 weeks). The leaves were highest, the stem tissues intermediate, and the reproductive structures lowest in As concentration. Within a narrow range of concentrations of As in the nutrient media both plants grew successfully, but they contained As concentrations in the tops in excess of the legal tolerance limit for the As content of foods. For equal relative reductions in yield the more resistant plant (Sudan grass) contained several times the concentration of As in the other species. Accumulated arsenical residues in soils as a result of insect and weed control practices are discussed as a source of As contamination in foods through absorption by plants. There are 28 references.

**Alkaloid and nitrogen metabolism in the germination of *Lupinus luteus*,** J. C. J. WALLEBROEK (*Rec. Trav. Bot. Néerland.*, 37 (1940), No. 1, pp. 78-132, figs. 3).—The author concludes from this study that the alkaloids of the yellow lupine take an active part in metabolism. During germination the amount of these compounds in the cotyledon decreases at the same time that it increases in the plumule and radicle. When germination occurs in darkness the decrease in the cotyledons exceeds that in the plumule and radicle during the first 3 weeks. This cannot be explained otherwise than by a decomposition of the alkaloids within the organism. If during germination one of the cotyledons is removed, a far-reaching alkaloid decomposition follows in the plumule and radicle. From this behavior it is believed that the alkaloids are not the rigid, immovable, and unassailable waste products of metabolism assumed by some investigators.

**The localization of the nicotine synthetic mechanism in the tobacco plant,** R. F. DAWSON. (Univ. Mo.). (*Science*, 94 (1941), No. 2443, pp. 396-397).—On the basis of the evidence at hand, the author states that nicotine is apparently synthesized in appreciable amounts only in the tobacco roots, its presence in the leaves of intact plants in higher concentrations than in either stalk or roots perhaps being due to translocation and accumulation.

**Water balance in the onion root: Relation of volume intake to volume exudate of excised roots and isolated root segments,** H. F. ROSENE (*Plant Physiol.*, 16 (1941), No. 3, pp. 447-460, figs. 2).—"Simultaneous determination of water absorption and exudation of excised roots and pieces of roots revealed that fluctuations in both inflow and outflow occurred from one 2-hr. interval to another in a saturated atmosphere at a temperature which did not vary more than  $\pm 0.5^{\circ}$  C. during long intervals. The variations in outflow and inflow may be opposite in direction during any one interval. The transport ratio of outflow to inflow, volume exudation : volume absorption, was seldom unity during the first interval following excision; with time the ratio approached or reached unity. Rates of both inflow and outflow usually increase with time during a 24-hr. period following excision. The direction of longitudinal transport through an isolated piece of root depends upon its age and upon its position on the longitudinal axis before cutting. Segments consisting of the apical third of young roots less than 70 mm. in length and less than a week old exhibit basal outflow only in an upright, inverted, or horizontal position with respect to gravity; segments from the middle and basal third exhibit outflow at both ends in all three positions. The direction of transport of basal segments cut from roots over 200 mm. in length and several weeks old depends upon the orientation of the segment with respect to gravity. Isolated segments of the root manifest the longitudinal gradient of distribution of rates of absorption characteristic of the excised and intact state." There are 19 references.

**A field method for the transpiration rate of grasses,** A. W. BAYER (*Ann. Natal Mus.*, 9 (1940), pt. 3, pp. 381-390).—Transpiring leaves are enclosed within weighed test tubes containing strips of filter paper impregnated with dry  $\text{CaCl}_2$ . Transpired water vapor is absorbed, and, by noting the gain in weight of the test tubes, the time for which the leaves were enclosed, and the leaf area, the transpiration rate for unit area in unit time can be calculated. A few applications to Natal grasses are given.

**Photosynthesis,** E. C. C. BALY (*New York: D. Van Nostrand Co.*, [1940], pp. VII+248, figs. 24).—The synthesis in living plants of carbohydrates from  $\text{CO}_2$  and water by the agency of sunlight is discussed as a problem in physical chemistry, and "the story is told of an investigation which led in the end to the photosynthesis in the laboratory of carbohydrates from carbon dioxide and water. In subsequent chapters the photosynthesis of proteins, the mechanism of photosynthesis, and the kinetics of the process are discussed."

**Plastid pigments, with special reference to their physical and photochemical properties and to analytical methods, F. P. ZSCHEILE.** (Ind. Expt. Sta.). (*Bot. Rev.*, 7 (1941), No. 11, pp. 587-648, figs. 3).—This analytical review (330 references) takes up the carotenoids and chlorophylls, considering the chemical relationships and reactions, adsorption characteristics, absorption spectra, analytical methods, and fluorescence spectra of both, and, in addition, the general physical properties and vitamin A activity of the carotenoids and the optical activity, film properties, protochlorophyll, and bacterial photosynthetic pigments with respect to the chlorophylls. Final sections discuss function in plants and previous reviews—viewpoints.

**Teor em clorofila das folhas de cafeeiros diversamente sombreados e a pleno sol [Chlorophyll content of coffee leaves variously shaded and in full sunlight], C. M. FRANCO** (*Rev. Inst. Café Estado São Paulo*, 16 (1941), No. 169, pp. 296-299, fig. 1; *Eng. abs.*, p. 299).—Measured colorimetrically, the amount of chlorophyll was less with increase in light intensity.

**Flower and berry production by potatoes as influenced by two light intensities and two midwinter planting dates, H. O. WERNER.** (Nebr. Expt. Sta.). (*Amer. Potato Jour.*, 18 (1941), No. 12, pp. 349-355, figs. 2).—Under an 18-hour day, flower and berry production were improved in midwinter by increasing the light intensity, accomplished either by increasing the intensity of the supplemental light or by planting later to obtain the benefit of the longer, brighter days. An increase in the average daily radiation from 226 to 254 gram calories per square centimeter appeared as effective in stimulating flowering and berry production in some varieties as increasing supplemental light from about 35 to about 115 footcandles. Increased daylight intensity was more beneficial to some varieties than increasing the supplemental light. Nine varieties which bloomed in April 1937 were not induced to bloom by any of the treatments here used.

**An annotated bibliography of the low temperature relations of plants, R. B. HARVEY** (Minneapolis, Minn.: Burgess Pub. Co., 1936, rev. ed., pp. [1]+II+240).—This bibliography is arranged alphabetically by author and provided with subject index.

**Relation of temperature to the ascorbic acid content of cowpea plants, M. E. REDD.** (U. S. D. A. et al.). (*Bul. Torrey Bot. Club*, 68 (1941), No. 8, pp. 519-530, figs. 5).—The rates of accumulation and disappearance of ascorbic acid, as well as the respiratory intensity and growth rate of cowpea seedlings in darkness, were successively higher at 22°, 26°, and 29° C. Differences in the total ascorbic acid content of plants grown at different temperatures were associated with differences in the amount and type of growth of the different organs. It is suggested that the lower maximum ascorbic acid content of seedlings grown in darkness at high temperatures may result from a greater metabolic loss of the vitamin or, less probably, from a decreased synthesis. Within an 18-hr. period in darkness appreciable losses of ascorbic acid from light-grown plants occurred only under temperature conditions favorable to growth. There was a lower total ascorbic acid content of plants grown in light at 29° than at 24°. Reasons are advanced to suggest that it may be chiefly a consequence of a more rapid rate of metabolic loss than of less rapid synthesis.

**Studies on the embryo of *Hordeum sativum*—I, The development of the embryo, J. MERRY** (*Bul. Torrey Bot. Club*, 68 (1941), No. 8, pp. 585-598, figs. 42).—The normal development of the barley embryo is described, and the development of the vascular system of the embryo is interpreted from plants grown in culture from embryos of different ages. The proembryo develops with no definite

arrangement or sequence of cell divisions. The scutellum and stem meristem begin to differentiate at 8 days after fertilization. The coleoptile is formed from a region which becomes the scutellum and is closely associated with the scutellum. The scutellum and the coleoptile are considered to be structures morphologically distinct from the foliage and peculiar to the embryo. The time of differentiation of the leaf primordia, the bundles of the leaves, and the seminal root primordia is given, and the vascular relationships of the various parts of the embryo are described.

**Seed development in Medicago (alfalfa) hybrids.**—I, **The normal ovule**, H. M. FARLEY and A. H. HUTCHINSON (*Canad. Jour. Res.*, 19 (1941), No. 11, Sect. C, pp. 421-437, figs. 22).—Seed production in alfalfa hybrids is related to many factors, primarily the cytological disturbances due to hybridization. The establishment of new balances results in strains which may occupy different habitats. Deficiencies may appear at one or more of the many stages during the complete process of growth and development. This study of the normal ovule, as a standard for comparison, deals particularly with the histogenesis and development of the nucellus, gynospores, integuments, funiculus, female gametophyte, embryo, and endosperm. Some of the food and nutrition problems associated with seed production are considered.

**The anatomy of the seedling and roots of the Valencia orange**, H. E. HAYWARD and E. M. LONG (*U. S. Dept. Agr., Tech. Bul.* 786 (1942), pp. 32, figs. 22).—Seedling development in *Citrus sinensis* is hypogeal, and frequently multiple seedlings arise from one seed complex, resulting in spatial competition. Anatomical and histological details are presented. Numerous root hairs are produced under favorable conditions, and these become suberized or lignified and may persist until a hypodermal periderm is developed. The hypodermis may produce secondary root hairs or absorbing areas consisting of groups of thin-walled, radially elongated cells. Lenticels also may be formed. Lateral roots of Valencia and other sweet orange strains resemble the primary root in ontogeny, but the number of primary xylem strands may range from three to eight, tetrarch and pentarch being the most common. Growth in length and secondary thickening are slow. Under unfavorable conditions, elongation is inhibited and the hypodermal periderm extends to the proximal margin of the root cap. The vascular transition occurs in a very short portion of the hypocotyl immediately below the cotyledonary node. The anatomy of the first internode and first foliage leaves is described.

**Structure of the cotton fiber as revealed by the microscope**, C. W. HOCK and R. C. RAMSAY (*Sci. Mo.*, 53 (1941), No. 6, pp. 519-523, figs. 6).

**Apomixis in the angiosperms**, G. L. STEBBINS, JR. (Univ. Calif.). (*Bot. Rev.*, 7 (1941), No. 10, pp. 507-542, fig. 1).—This comprehensive review (six pages of references) aims partly to revise and enlarge the one by O. Rosenberg<sup>1</sup> and partly to show the connection between the problems of apomixis and other major problems. The subject matter is discussed under terminology and description of the phenomena, evidence from apomixis as to the nature of meiosis, apomixis and the alteration of generations, hypotheses as to the cause of apomixis, and apomixis in relation to species differentiation and plant distribution—the agamic complex.

**The protoplasmic membrane regarded as a complex system**, H. L. BOOIJ (*Rec. Trav. Bot. Néerland.*, 37 (1940), No. 1, pp. 1-77, figs. 76).—The four chapters of this monographic study deal, respectively, with a general introduction to the subject, experiments with *Lathyrus*, the influence of various compounds on

<sup>1</sup> Handb. Vererbungsw., 2 (1930), I, pp. [1]+66, figs. 32.

baker's yeast, and general conclusions regarding the selection of experiments from which the structure of the membrane can be derived and the protoplasmic membranes of *Lathyrus* pollen and bakers' yeast. There are 101 references.

**Clave de generos para clasificar bacterias con arreglo a la quinta edicion del libro de Bergcy** [Key to bacterial genera according to the classification in the fifth edition of the Bergcy manual], C. A. BLERACHINI (*Agronomia* [Buenos Aires], 30 (1940), No. 1, pp. 51-70).—This is a key to the book previously noted (E. S. R., 81, p. 489).

**A nucleus-like structure in a staphylococcus**, G. KNAYSI. (Cornell Univ.). (*Science*, 94 (1941), No. 2436, p. 234).

**Inactivation of enzymes as the cause of death in bacteria**, O. RAHN and W. R. SCHROEDER. (Cornell Univ.). (*Biodynamica*, 3 (1941), No. 68, pp. 199-208).—According to some biologists, death of the cell is due to the inactivation of its enzymes. The "logarithmic order of death" of bacteria is believed by some to be the necessary consequence of the "logarithmic order of enzyme coagulation." All experimental evidence at hand indicates that it is possible to kill the cell without destroying the enzymes. A study of the death of cells and of the loss of enzyme activity in *Bacillus cereus* under the action of heat indicated that previous evidence considered to support the enzyme theory of death involved faulty technic. The monomolecular inactivation of enzymes is said to have nothing to do with the logarithmic order of death. "If there are many enzyme molecules per cell, all the cells would reach the same stage at the same time and not in a logarithmic sequence. If inactivation of only a few molecules causes death, the order will resemble that for higher organisms. The logarithmic order is established only if death is caused by the reaction of one single molecule."

## GENETICS

**Accion biologica de las radiaciones en relacion con la produccion de mutaciones en los vegetales** [Biological action of radiations in relation to the production of mutations in plants], F. WORSCHITZ (*Agronomia* [Buenos Aires], 30 (1940), No. 1, pp. 37-50, figs. 6).—An address referring to the effects of such irradiations as ultraviolet light, X-rays, and radium.

**An inversion, a reciprocal translocation, trisomics, and tetraploids in barley**, L. SMITH. (U. S. D. A. coop. Mo. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 63 (1941), No. 12, pp. 741-750, figs. 2).—Cytological studies were made on barley plants mainly from varieties and strains of *Hordeum vulgare*. About 20 percent of the pollen mother cells in two plants of one progeny had a bridge or fragment or both at the first division, configurations interpreted as due to crossing over in a heterozygous inversion. A reciprocal translocation is described. Limited observations indicated that in about 60 percent of the pollen mother cells, segregations of the chromosomes were disjunctional. Fertility was about 65-percent perfect in three ring-forming plants. Observations on meiosis in two of three trisomic plants are recorded. Meiosis, fertility, and chromosome number in three strains of tetraploid barley were also described. Examination of mutants and varietal hybrids revealed a melotic disturbance as characteristic of only one mutant.

**The occurrence of a spontaneous triploid celery**, T. W. WHITAKER. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 346-348, fig. 1).—A single plant, apparently a hybrid of *Apium prostratum* and *A. graveolens* (the common celery), found in a planting of the first species is described. The presumed hybrid had 33 somatic chromosomes as compared with 22 in each of the sup-

posed parents. Only a small percentage (from 5 to 10) of the pollen appeared viable, and the plant was completely sterile. The hybrid flowered in the first year and had since assumed a perennial habit. It is suggested that this plant arose through failure of reduction at meiosis of one parent and the consequent fusion of the reduced gamete with an unreduced gamete. Backcrosses of the triploid to both parents failed to produce viable seed.

**Productivity of  $F_1$  hybrids in the squash, *Cucurbita maxima*, A. E. HUTCHINS and F. EL. CROSTON. (Minn. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 332-336).—A study of total yields, yield of mature fruit, weight per fruit, number of fruits per plant, and maturity in 10 squash crosses and their parents showed that seven of the  $F_1$ -generation hybrids produced significantly higher yields than the more productive parent. In general,  $F_1$ s of crosses between parents differing considerably in their external characters were more productive than those of crosses between closely related strains. The combined effect of weight per squash, number of squashes per plant, and maturity appeared to influence increases in yield. In eight reciprocal crosses, there was no difference in total yield in the  $F_1$ . In three others between large- and small-seeded parents there was a significantly greater yield when the larger-seeded variety was used as the mother parent. It is suggested that the difference may have resulted from the restricting effect of the seed coat of the smaller-seeded parent on the  $F_1$  embryo.**

**Size inheritance in tomato fruits, J. W. MACARTHUR (*Jour. Hered.*, 32 (1941), No. 9, pp. 290-295, figs. 3).—Plants of four tomato varieties and of the six  $F_1$  crosses between them, grown under like conditions, were set in the field in a 10 x 10 Latin-square arrangement with border plants. The weights of from 10 to 20 mature fruits recorded for each plant revealed distinctly orderly and predictable relations. It was evident that size genes determining fruit weight in the tomato had acted in a proportionate or geometric manner.**

**[Experiments in animal genetics and physiology of reproduction by the Bureau of Animal Industry]. (Partly coop. expt. stas. et al.). (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.*, 1941, pp. 4, 5, 11-12, 13-14, 17, 18, 19-21, 25-27, 28, 29-30, 31-33, 35-40).—There are included progress reports on investigations on record of performance and the inheritance of growth and conformation in horses, cattle, sheep, swine, and poultry; collection and preservation of semen and artificial insemination of cattle, sheep, and swine; inheritance of intelligence and temperament in dogs; effects of inbreeding strains of mice; steroids and sex hormones; inheritance of qualities for beef and lamb production; cross-breeding in sheep and cattle; transmission of meat qualities in rabbits; lot feeding cattle for progeny testing; ovulation, morphology of ram sperm, fertility, and movement of sperm in the genital tract of ewes; sire testing and establishment of lines in sheep; inbreeding Rambouillets; duration of gestation in range sheep; breeding and inheritance of quality of staple and covering in fleece of Rambouillet and Navajo sheep; line-breeding of milk goats for milk and butterfat production and inheritance of hermaphroditism in goats; reproductive efficiency of sows and scoring market pigs; pregnancy determination in swine; improvement of swine through application of breeding methods; physiological study of artificial insemination and reproduction in mares; inheritance of tendency to blood spot formation and physiology of egg formation and quality in poultry and relation of endocrines, especially the pituitary, to reproduction; breeding turkeys for small size; and breeding, management, nutrition, and pathology for improved viability at the Regional Poultry Research Laboratory.**

**[Genetic studies by the Alabama Station] (*Alabama Sta. Rpt.* 1940, pp. 23, 29-30).—Studies by J. C. Grimes and P. D. Sturkie deal with the hereditary**

factors associated with economy of gains in swine and the effects in poultry of induced changes in the developmental environment of certain genes.

[Genetics and physiology studies with animals at the Colorado Station] (*Colorado Sta. Rpt. 1941, pp. 15, 36*).—Brief reports are presented on the occurrence of parrot mouth in lambs sired by one ram and on the relationships of thyroid to thymus and of thyroid to gonadotropic hormones.

Primenenie serologicheskikh metodov v izuchenii neskreshchiyaemosti pri otdalenoj gibrizizatsii (Application of serological methods in investigation of incompatibility in distant crosses), I. I. SOKOLOVSKAJA (I. I. SOKOLVSKAJA) (*Akad. Nauk. S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.), No. 13 (1940), pp. 249-276, figs. 7; Eng. abs., pp. 275-276*).—Antibodies to the spermatozoa of different species and a high antiembryonic titer of the blood of ♀ goats pregnant with hybrid embryos are taken as indications of incompatibility between the different species.

Izmenchivost' i nasledovanie prodolzhitel'nosti embrional'nogo razvitiia (Variability and inheritance of the duration of embryonic development). B. N. VASIN (VASSIN) (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.), No. 13 (1940), pp. 155-174, figs. 2, Eng. abs., pp. 173-174*).—Differences in the embryonic development within different breeds of rabbits, pigs, sheep, and cattle are so great as to be regarded as breed characteristics. It is pointed out that the gestation periods of these animals, except for the pig, are inversely in the order of the number in the litter. Season, sex of the fetus, and age of the dam are also influential factors.

K genetike biokhimičeskikh priznakov u zhivotnykh v svyazi s ikh rostom (A contribution to the genetics of the biochemical characters in animals in relation to their size), V. I. PATRUSHEV (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.), No. 13 (1940), pp. 121-153, figs. 6; Eng. abs., pp. 152-153*).—The glutathione concentration of cattle and sheep differed according to breed, but the individual animals remained relatively constant, gradually decreasing after 3 yr. of age. The catalase index was higher in calves than in adults, but there was no reduction with age in adult animals. On an average, body weight was associated with glutathione concentration and catalase activity in the blood.

Polosatye domashnie loshadi (Stripings in domesticated horses), I. A. I. A. (J. J.) LUS (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.), No. 13 (1940), pp. 297-319, figs. 15; Eng. abs., p. 319*).—Striping in horses occurs in many domestic breeds as a mutation analogous to brindling in cattle and dogs.

Sostav krovi krupnogo rogatogo skota v svyazi s ego produktivnost'iu (Blood content of cattle in relation to their productivity), K. F. (H. F.) KUSHNER (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.), No. 13 (1940), pp. 95-120, figs. 9; Eng. abs., pp. 119-120*).—A definite correlation was found between the oxidizing ability of the blood, as determined by hemoglobin content and number and size of erythrocytes, and the rate of growth and productivity in cattle. Bulls had a greater concentration and smaller size of erythrocytes and a higher hemoglobin content than cows, but the reverse occurred in calves.

Khromosomy v spermatogeneze odnogorbogo verbljuda (*Camelus dromedarius* L.), dvugorbogo verbljuda (*Camelus bactrianus* L.) i F<sub>1</sub>-gibrida mezhdu nimi (Chromosome behaviour during spermatogenesis in camels *Camelus dromedarius* L. and *Camelus bactrianus* L. and their F<sub>1</sub>-hybrid), I. I. NOVIKOV (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.), No. 13 (1940), pp. 285-296, figs. 3; Eng. abs., pp. 295-296*).—No particular distinctions could be found in the

form or number of chromosomes between dromedary and bactrian camels or hybrids between them. The haploid number was 35 in all cases, and there seemed no reason for sterility.

**Sostav krovi oveš v sviazi s ikh produktivnost'ŭ (Blood content in sheep in relation to their productivity)**, K. F. (H. F.) KUSHNER (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.)*, No. 13 (1940), pp. 57-94, figs. 6; *Eng. abs.*, pp. 92-94).—Studies of the hemoglobin and blood values of sheep showed that the greatest body weight was displayed by animals which possess a higher hemoglobin content and greater concentration of erythrocytes. These findings occurred between breeds and within breeds. The highest hemoglobin content and largest concentration of erythrocytes were displayed by newborn lambs and decreased to 7-14 days of age, followed by increases in ewe lambs 40-50 days of age and in yearling ewes. The diameter of the erythrocytes was  $0.3\mu$  smaller in ♂s than in ♀s.

**Nasledovanie pegostei u chernykh karakulevykh oveš (Inheritance of white spottings in black Karakul sheep)**, E. P. PANFILOVA (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.)*, No. 13 (1940), pp. 331-338, figs. 3; *Eng. abs.*, pp. 337-338).—There was found to be a correlation between the white spotting on the back of Karakul sheep and white spots on the tail and head, thus permitting breeding of one parent having white spotting on the tail only with an all-black animal.

**Opyt gibrizatsii dikogo barana arkhara (Ovis polii karelini Sev.) s merinosami novokavkazskogo tipa (Ovis aries hispanica) (Interspecific hybridization between the wild sheep (Ovis polii karelini Sev.) and New-Caucasian Merino sheep (Ovis aries hispanica)**, N. S. BUTARIN (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.)*, No. 13 (1940), pp. 175-247, figs. 30; *Eng. abs.*, pp. 223-226).—Hybrid lambs were produced by New-Caucasian Merino ewes through artificial insemination with sperm from wild Arkhar rams shot in the mountains. They showed a general dominance of the weights, measurements, and temperament of the wild type. The 60 lambs so produced by 58 ewes were like the Arkhar parent, were heavier than Merinos, and grew more rapidly. All progeny from crosses with horned Merinos had horns, but from crosses with hornless Merino sheep all the ♂s and 9 ♀s were horned and 6 ♀s were hornless. The form of the horns was that of the Arkhar. The wool qualities of the F<sub>1</sub> were inherited mainly from the Merino, although there was not complete dominance, but the structure of the fiber was from the Arkhar. In color there was dominance of the white of the Merinos, but other factors or modifiers produced over 90 percent F<sub>1</sub> progeny with red in the wool. The 2n chromosome number of both species was 60.

**Analiz potomstva barana porody karakul', osemenivshego 5 tys. matok (Analysis of the offspring of a Karakul ram used for insemination of 5,000 ewes)**, E. P. PANFILOVA (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.)*, No. 13 (1940), pp. 321-329; *Eng. abs.*, p. 329).—The lambs produced by ewes having fleeces of different quality showed that the best-grade Karakul lamb fleeces were produced by the progeny of fine-curl dams.

**A note on the effect of multiple births on the sex ratio in sheep**, K. RASMUSSEN (*Sci. Agr.*, 21 (1941), No. 12, pp. 759-760).—Among 3,711 lambs born in several breeds from 1934 to 1940 there were excesses of ♀s among the twins or like sex in all of the breeds. In singles there was an excess of ♂s.

**Die physiologischen Verhältnisse beim Gebärrakt des Schweines und ihre Beziehungen zu einigen Leistungsausserungen [The physiological relations of parturition in swine and their relation to reproductiveness]**, H. SCHÄFER (*Ztschr. Tierzücht. u. Züchtungsbiol.*, 48 (1941), No. 3, pp. 207-254).—The rela-

tions of various conditions, such as parity, season, weight, mortality, and sex of the young, are tabulated for 1,002 young born in Landschweine and pure German Berkshire litters and crosses between them. In general, it was found that the first to fourth litters of a sow usually had a shorter gestation period, with higher livability, than the fifth to eighth litters. Importance is attached to the length of time of birth.

**Genetic aspects of pigment production in the guinea pig, M. T. HARMAN and A. A. CASE.** (Kans. State Col.). (*Genetics*, 26 (1941), No. 5, pp. 474-486, figs. 3).—In a histological study of the pigment formation in the guinea pig, as described by Bogart and Ibsen (E. S. R., 78, p. 769), blocks of skin from fetuses 43 to 57 days of age and a few newborn and adult animals were fixed and correlated with the appearance of the living animal at various ages. Two types of pigment, granular and diffuse, were observed. The granular type was red, black, chocolate, or colorless. Diffuse pigment ranged in shade from pale yellow to a deep red-brown. The earliest stage of pigment formation was observed in 43-day fetuses. Diffuse reddish pigment was found in *O* red and dark hairs and in *c'* dark hairs, but not in *c'* and *c''* white hairs. The influence of different genes on the color of hair is concluded to be as follows: "The factor *B* may determine the presence of dark granules. The factors *B* and *b* determine whether these granules are black or chocolate. The factor *c* in the homozygous condition may determine the presence of red granules. The factors *B* and *b* may produce 'dark' and 'light' red granules. In the presence of the factor *C*, both *B* and *c* may act as described above. In the presence of the factor *c'*, in the homozygous condition, *B* may act as described, but *c* may produce only colorless granules or none at all. Where the factor *c''* is present in the homozygous condition, *B* does not produce dark granules and *c* does not produce red granules. Unless other factors are present, the hairs of *c'ce* and *c''c''* animals are white. The action of the factors in the light and dark areas of *c''* (spotted) animals corresponds to that in *c* and *B* animals, respectively. In the skin, the factors *B* and *b*, *C*, *c'* and *c''* may affect the amount rather than the kind of pigment present. Where there is a small amount, it is found chiefly in the extremities. The factors *B* and *b* may control the color of the pigment in the skin and act in the presence of either *B* or *c''*."

**Sensitivity to estrogen studied by means of experimentally induced mating responses in the female guinea pig and rat, J. G. WILSON and W. C. YOUNG** (*Endocrinology*, 29 (1941), No. 5, pp. 779-783).—The response of guinea pigs ovariectomized at birth and at 30 and 85 days of age to 10 rat units of oestradiol benzoate, followed by 0.1 International Unit of progesterone 48 hr. later, showed by the manual mating response of Blandau et al. (noted below) that the sensitivity increased greatly during the first month of life. At 7 days, the animals were insensitive, but by the thirtieth day of age the threshold was maintained to at least the twenty-fourth month. The response was independent of uterine and ovarian influences, since similar results were obtained in ovariectomized guinea pigs and rats, with and without hysterectomy. The rat maintained its 30-day sensitivity through at least the tenth month.

**The length of heat in the albino rat as determined by the copulatory response, R. J. BLANDAU, J. L. BOLING, and W. C. YOUNG** (*Anat. Rec.* 79 (1941), No. 4, pp. 453-463, fig. 1).—The average length of 609 heat periods ascertained by reaction to manual manipulation in 114 rats was 13.7 hr. The beginning of heat was most frequent between 4 and 10 p. m., and 87 percent of 567 cycles were from 4 to 6 days in length, with an average of 4.4 days. Hourly tests for sexual receptivity were made for the determination of the stages of the cycle, and, although there was individuality exhibited in successive cycles,

the method did not interfere with the duration or recurrence of successive cycles.

**The vaginal smear picture, sexual receptivity, and time of ovulation in the albino rat,** W. C. YOUNG, J. L. BOLING, and R. J. BLANDAU (*Anat. Rec.*, 80 (1941), No. 1, pp. 37-45).—Behavior of the animal was considered the best indication of the beginning and end of oestrus and ovulation in the rat. Observations on a group of normal ♀ rats showed that the beginning of heat was usually associated with the first appearance of cornified epithelial cells, but the end of heat was not so closely marked. In most cases the end of heat was marked by the reappearance of nucleated epithelial cells. Ovulation was often associated with the normal condition, but in most animals it occurred when cornification was complete.

**The duration of the fertilizing capacity of spermatozoa in the female genital tract of the rat,** A. L. SODERWALL and R. J. BLANDAU (*Jour. Expt. Zool.*, 88 (1941), No. 1, pp. 55-64).—Estimation of ovulation by the methods noted above indicated the maximum duration of fertilizing capacity of rat spermatozoa introduced by artificial insemination in 184 ♀s as 14 hr., but there was a definite reduction in fertilizing ability of spermatozoa kept in the ♀ tract 10 hr. or longer before ovulation. No abnormal pregnancies or modified sex ratios were noted, but litter size was reduced.

**An hereditary absence of the incisor teeth,** R. O. GREEP (*Jour. Hered.*, 32 (1941), No. 11, pp. 397-398, figs. 2).—A tooth anomaly in which the incisors failed to appear was noted in rats. The condition behaved as a simple recessive to the normal. One pair of defective animals produced 11 progeny, all without incisors. Expected results were obtained in matings of homozygous and heterozygous normals. Anomalous animals in the colony also showed a hemorrhagic exudate from the eyelids.

**Crosses between inbred strains of mice,** O. N. EATON. (U. S. D. A.). (*Jour. Hered.*, 32 (1941), No. 11, pp. 393-395).—The weights, growth, and viability of inbred, crossbred, and backcross strains of mice largely substantiated the principles previously set forth for the guinea pig (E. S. R., 85, p. 177). The crossbred strains and progeny from them largely surpassed the inbred and random-bred strains, respectively, in percentage of successful matings, size of litter at birth and at weaning, and in birth and weaning weights. The viability and weights of a synthetic strain produced by the intermating of F<sub>1</sub> hybrids gave promise in the development of a superior strain.

**Studies on hereditary congenital baldness in the domestic fowl.—I, Embryological and physiological bases of the character,** P. D. STURKIE. (Cornell Univ.). (*Jour. Morphol.*, 69 (1941), No. 3, pp. 517-535, figs. 9).—Congenital baldness in fowls due to a recessive autosomal gene was associated with bleb formation of 6- to 11-day-old embryos. Microscopic study of the blebs of the embryos showed them to form by the separation of the dermis from the epidermis with the accumulation of bleb fluid and to prevent feather formation. There was a complete absence of feather papillae in the bald areas.

**Vozrastnaja izmenlivost' ekster'era u utok (Variability of external forms during the post-embryonic development in ducks),** B. F. RUMJANTSEV (RUMJANCEV) (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.)*, No. 13 (1940), pp. 43-55, figs. 2; *Eng. abs.*, p. 55).—Various breeds of ducks possessed peculiarities characteristic of their breeds, although they followed the general pattern characteristic of mammals.

**O karlotipakh nekotorykh ptits (A contribution to the karyotypes of certain birds),** I. I. SOKOLOVSKAJA (I. I. SOKOLOVSKAJA) (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.)*, No. 13 (1940), pp. 277-284, figs. 4; *Eng.*

abs., pp. 283-284).—The morphology of the chromosomes of ducks, pheasants, and pigeons is compared.

**How hatcherymen can solve the sexing problem**, T. C. BYRLEY. (Univ. Md.). (*Md. Agr. Soc., Farm Bur., Rpt.*, 25 (1940), pp. 319-320).—An outline is given of the methods of separating sexes by sex-linked characters.

**Opyty po epigamnomu pereopedeniiu pola ptits (Attempts on induction of epigamic sex reversion in birds)**, I. I. SOKOLOVSKAIA (I. I. SOKOLOVSKAJA) and V. K. MILOVANOV (*Akad. Nauk S. S. S. R., Trudy Inst. Genet. (Bul. Inst. Genet.)*, No. 13 (1940), pp. 339-346; *Eng. abs.*, p. 346).—The sex ratios of chicks hatching from eggs injected with novo-ovaricin into the air chamber on the third to sixth and seventh to twelfth days of incubation were 38.8 percent ♂ and 67.2 percent ♀, with a mortality of 33.8 percent. The sex ratio was modified by the greater mortality of the ♂s. The sexes of chicks from eggs uninjected and eggs injected with folliculin approached equality, and mortality was reduced.

**Interaction of antigens in dove hybrids**, R. W. CUMLEY and M. R. IRWIN. (Wis. Expt. Sta.). (*Jour. Hered.*, 32 (1941), No. 12, pp. 429-434, figs. 3).—A pictorial representation of the antigenic relations of Pearlneck and ringdoves and the  $F_1$  between them, previously noted (E. S. R., 86, p. 178), showed the operation of one antigen or group of antigens common to all three types, other antigens specific for each of the three types, and fifth and sixth antigens or groups of antigens common to the  $F_1$  and one or the other species.

**A new diluent for bovine semen**, C. E. KNOOP. (Ohio Expt. Sta.). (*Jour. Dairy Sci.*, 24 (1941), No. 10, pp. 891-892).—Motility was maintained for an average of 12.5 days in 50 percent of bovine spermatozoa by holding semen samples in a diluent consisting of gelatin,  $KH_2PO_4$ ,  $Na_2HPO_4 \cdot 12 H_2O$ , and fresh egg yolk at from 4° to 6° C. The semen was collected and diluted under sanitary conditions with gradual cooling to 5°. Without gelatin in the diluent, motility was maintained an average of only 8.3 days in 50 percent of the spermatozoa.

**Influence of age and presence of the ovaries on reproductive function in rats injected with androgens**, J. G. WILSON, J. B. HAMMILTON, and W. C. YOUNG (*Endocrinology*, 29 (1941), No. 5, pp. 784-789).—In further studies of the effect of testosterone propionate injections on the reproductive functions of ♀ rats (E. S. R., 84, p. 749), injections of 36 mg. administered in 12 doses over a period of 4 weeks, begun at 15, 20, 30, 40, or 120 days of age, had no effect on the mating response to oestradiol benzoate. Permanent defects in ovarian structure and mating response to oestrogens followed injection of the androgen begun at 5 and 10 days of age. Ovariectomized animals gave similar responses, showing that the decreased response to oestrogen caused by androgens did not result from ovarian secretions.

**Studies on the histology and physiology of the pituitary of rats treated with progesterone**, E. CURTLY (*Endocrinology*, 29 (1941), No. 5, pp. 695-707).—In no case did injections of from 0.5 to 3 mg. of progesterone per day into castrated ♂ and ♀ rats, whether administered immediately after castration or when delayed, correct castration changes in the anterior pituitary. Progesterone was also found to be a weak gonadotropic depressant in parabiotic rats, more than 3 mg. daily being required for an effective dose. Progesterone did not show any selective inhibitory action on the tubular and interstitial elements of the testis. The study was conducted with 19 castrated ♂ and ♀ rats with their controls and 7 parabiotic pairs.

**Purification of thyrotropic hormone of the anterior pituitary**, J. and H. FRAENKEL-CONRAT, M. E. SIMPSON, and H. M. EVANS. (Univ. Calif.). (*Jour. Biol. Chem.*, 135 (1940), No. 1, pp. 199-212).—Details of the purification of the thyrotropic hormone from extracts of beef anterior pituitaries are described.

The final product represented a hundredfold purification with recovery of about one-third of the total thyrotropic activity. It contained about 10 percent of the interstitial cell-stimulating hormone but little of the lactogenic, adrenocorticotrophic, growth-stimulating, or follicle-stimulating hormones.

**Effect of testosterone propionate on various responsive organs of immature rats,** W. FREEMAN and R. SMALL (*Endocrinology*, 29 (1941), No. 5, pp. 758-761, fig. 1).—The uterus was found to be by far the most sensitive target organ in studies of the effects of doses of 0.5, 1, 2, 4, 8, and 10 mg. of testosterone propionate administered on three successive days to 20- to 25-day-old litter-mate rats. The most sensitive organ-indicator in ♂s was the ratio of the seminal vesicle to prostate weight, but this was less responsive than the uterus. Doses as small as 0.2 mg. were effective in stimulation of uterine growth. Determinations were made of other organ weights, including the ovaries, testis, and thymus.

**Molecular-equivalents versus weight-equivalents in the potency of androgenic substances,** E. OPPENHEIMER, R. R. GREENE, and D. NELSON (*Endocrinology*, 29 (1941), No. 5, pp. 755-757).—After 21 days' treatment with daily doses of 0.2 mg., applied in an ointment by inunction to castrated rats, testosterone produced prostates significantly heavier than those produced by testosterone propionate. However, when administered on a molecular-weight basis, 0.239 mg. of testosterone propionate was no longer inferior to 0.2 mg. of testosterone.

**Body and muscle growth in normal and castrate albino mice,** P. ENGEL (*Endocrinology*, 29 (1941), No. 5, pp. 852-853).—There was almost no difference in the weights at 2 mo. of age among groups of 10 normal rats and 10 rats castrated at 17 mg. in weight, but the leg muscles in relation to body weight were much heavier in normal ♂s.

## FIELD CROPS

**Bibliography of field experiments,** H. M. STEECE, F. R. IMMER, and H. M. TYSDAL (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 12, pp. 1049-1052; 32 (1940), No. 12, pp. 984-986; 33 (1941), No. 12, pp. 1124-1127).—Additions to the bibliography on standardization of field experiments as revised and supplemented (E. S. R., 80, p. 758) comprise 197 titles of contributions on methodology and interpretation of results of field and grassland research.

**How to determine which of two variables is better for predicting a third variable,** W. D. BATEN. (Mich. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 33 (1941), No. 8, pp. 695-699, figs. 2; *abs. in Michigan Sta. Quart. Bul.*, 24 (1941), No. 2, p. 152).—Applications of Hotelling's test for determining which of two variables is better for predicting a third when the variables are linearly related pertain to length of a wheat spike v. number of spikelets with grain per spike to predict number of kernels per spike and to length v. width to predict areas of bean leaflets.

**[Agronomic research in Alabama, 1940]** (*Alabama Sta. Rpt. 1940*, pp. 21-22, 30, 39-40, 41, 45).—Experiments with field crops and related research at the station and substations (E. S. R., 85, p. 470) are reported by H. R. Albrecht, E. L. Mayton, D. G. Sturkie, H. B. Tisdale, J. B. Dick, J. T. Williamson, F. E. Bertram, J. K. Boseck, R. C. Christopher, H. A. Ponder, J. W. Richardson, R. W. Taylor, E. V. Smith, C. L. Isbell, J. F. Duggar, and H. S. Swingle. The studies comprised cotton breeding; variety tests with corn; response of kudzu to fertilizer treatments; the effect of method of preparation of land for cotton on the properties of the fiber and the composition of the seed; comparisons of fertilizers of different analyses applied at different rates for cotton; experiments to determine a practicable combination of times of plant-

ing and harvesting and storage methods to be used with sweetpotatoes on the average farm to provide a supply for home use throughout the year; differences among white clover strains in germination and effects of scarification on germination and stands; effects of exposure on the soil surface on germination of untreated crotalaria seed and seed production from different planting rates; stands from scarified sericea lespedeza seed sown at different rates; effects of crotalaria and sericea plowed under on corn yields and of 2-yr. sericea stubble on Sudan grass growth; control of *Najas* (*Najas guadalupensis*) and *Potamogeton* sp. in fish ponds by fertilization, spatterdock (*Nuphar advena*) by cutting, and watershield (*Brasenia schreberi*) by leaf removal; and the life history of nutgrass (*Cyperus rotundus*) as related to possible methods of control.

[Field crops and range research in Colorado]. (Partly coop. U. S. D. A.). (Colorado Sta. Rpt. 1941, pp. 9-10, 12, 18, 30, 41-44).—Crops investigations (E. S. R., 84, p. 612) reported on briefly included breeding work with corn (and hybrids), barley, and sorghums; determination of linkage relationships in barley; breeding work and variety and fertilizer tests with potatoes; studies on natural revegetation of native range, involving different grazing methods, experiments on increasing the grazing capacity of sagebrush lands, artificial reseeding with native and introduced grasses of depleted range and abandoned croplands and measurement of their grazing capacities, comparison of sources of seed of native grasses, a study to ascertain the extent of damage to range forage by grasshopper defoliation, and range resource surveys; and weed control.

The effect of green-manure crops on certain properties of Berks silt loam, S. S. OBENSHAIN and P. T. GISH (*Virginia Sta. Tech. Bul.* 73 (1941), pp. 12, figs. 2).—Effects on corn yields of eight green manures sown in the corn at the last cultivation were measured on Berks silt loam near Staunton. The green manures were compared with sodium nitrate and no green-manure crop or N fertilizer as to effects on corn yield and cumulative effects on certain soil properties. Average yields for corn crops harvested 1924-29, 1933-34 were in the order vetch, crimson clover, red clover, sodium nitrate, soybeans, sweetclover, cowpeas, check, rye, and buckwheat. Organic matter and N contents of all soils were increased over the check, but the increases were very small after rye and buckwheat. The C-N ratio of the soil varied from 8.58 on the plot receiving sodium nitrate to 11.42 on the plot growing rye as a green manure. Organic matter content of the soil was very closely related to all physical properties studied. Differences evident in the workability of the soil on the different plots were not reflected in plow-draft measurements.

The grasslands of Latin America, R. O. WHYTE (*Chron. Bot.*, 6 (1941), No. 19-20, pp. 443-446).—A review (18 references).

A comparison of Hardigan and Ladak alfalfa in their reactions to leafhopper infestation, S. T. DEXTER. (Mich. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 33 (1941), No. 11, pp. 947-951, fig. 1).—Hardigan and Ladak alfalfa reacted in a similar manner to leafhopper injury and to the general effects of cutting management. In neither variety did relatively severe leafhopper infestation occasion serious reduction in cold resistance, or in carbohydrate storage, or in subsequent yield of the plants. Such reduction does not appear likely under comparable conditions, provided cutting or grazing management is such that abundant organic reserves are stored before heavy freezes occur.

Effects of boron on yield and duration of alfalfa, T. B. HUTCHESON and R. P. COCKE (*Virginia Sta. Bul.* 336 (1941), pp. 9, figs. 5).—Experiments, 1939-41, at Williamsburg and Chatham wherein borax was applied to alfalfa grown on fertilized and limed plots and at several rates per acre demonstrated that B deficiency in alfalfa soils might be corrected by applications of from 10 to 20 lb.

of commercial borax to the acre, either when the crop is planted or as top dressings before spring growth starts. Such applications of borax on B-deficient soil will increase alfalfa hay yield greatly, stimulate alfalfa seed production, and increase the thickness and duration of the stand. Borax may be applied after any cutting of hay if B deficiency symptoms, i. e., yellow and reddish-purple colored leaves accompanied by stunted plant growth and abortive bloom buds, have been noted. It may be applied with fertilizers, lime, or other convenient carriers used in quantities enough to insure even distribution. Since borax used in excessive quantities is toxic to many crops, not more than 20 lb. to the acre should be applied annually for alfalfa and used only experimentally on other field crops if at all.

**Reducing barley failures in Maryland,** R. G. ROTHGER. (Md. Expt. Sta.). (*Md. Agr. Soc., Farm Bur., Rpt., 25 (1940), pp. 204-207*).—Varieties, cultural operations, and disease treatments are suggested to insure crops of barley.

**Factors affecting the germination of bulblets of bulbous bluegrass, *Poa bulbosa*,** V. K. TOOLE. (U. S. D. A.). (*Jour. Amer. Soc. Agron., 33 (1941), No. 11, pp. 1037-1045, figs. 5*).—Bulblets about 1 mo. old germinated better at 5° C. than at 10° or 20° constant temperatures and better with potassium nitrate than with water. Those about 4 mo. old also germinated better at 5° than at 10° or 20°. Germination at a temperature alternation of from 5° to 15° was faster than at a constant temperature of 5°, but complete germination of viable bulblets was obtained only by prechilling bulblets at 5° for 7 or 14 days followed by germination at 10°. As bulblets aged they tolerated higher germination temperatures. Bulblets about 2 and 4 yr. old germinated faster at 20° than at lower temperatures, but final germination was comparable at 10°. The 2-year-old bulblets required 49 days for completion of germination at 5°.

Bulblets containing about 13 percent of moisture, stored unsealed at room temperature, afterripened so that after 10 months' storage they germinated equally well at 5°, 10°, or 20°, but had fallen in viability after 25 months' storage. Similar bulblets stored in sealed containers at 10° or at 2° showed no appreciable loss of viability in 25 mo., and maximum germination was obtained at 5° and at 10° but not at 20°. Those stored at -10° became more resistant to germination conditions tried, and maximum germination was not obtained.

**Bulk emasculation and pollination of smooth bromegrass, *Bromus inermis*,** W. E. DOMINGO. (Utah Expt. Sta. coop. U. S. D. A.). (*Jour. Amer. Soc. Agron., 33 (1941), No. 11, pp. 993-1002*).—Panicles of relatively self-fertile plants of smooth bromegrass were emasculated completely by immersion in hot water, which gave the more consistent results, or by subjection to hot air. Hot-water treatments between 45° and 49° C. on more than 40 panicles a few days before normal anthesis decreased selfed seed set to less than 1 seed per panicle and permitted an average production of 52 seeds per panicle exposed to atmospheric pollen. Bulk pollen transfers, made to unemasculated panicles by bag transfer, isolation of panicles of male and female parents together, enclosure of severed panicles of male parent in the isolation bag of the female parent, and air currents over either severed panicles or intact stems of the male parent, produced significant amounts of hybrid seed. Bulk pollen collected from the male parent at anthesis and applied to panicles of the female parent with an atomizer did not produce much hybrid seed. Under conditions in isolation bags at time of normal anthesis in the field, pollen lost much viability within 24 hr. after shedding. Collected in bulk under atmospheric conditions, it quickly formed large aggregates.

**A method of measuring the strength of attachment of cotton fibers to the seed and some results of its application,** W. S. SMITH and N. L. PEAFF. (*U. S. Dept. Agr., Agr. Market. Serv. and Bur. Plant Indus., 1941, pp.*

*figs. 5).*—A simple instrument of the pendulum type and appropriate technic were developed for measuring the force required to detach single fibers from the cottonseed. With it a skillful operator could attain the same accuracy as with a McKenzie single-fiber tester, which was found too time-consuming. When tufts of fibers were pulled from the seed by an apparatus for testing single strands of yarn, figures calculated to represent strength of fiber attachment to the seed for the cotton as a whole, for individual seeds, and for fibers at different positions on the seed were smaller than figures representing the mean strength of fiber attachment obtained by testing individual fibers and are not considered to be accurate enough for fundamental studies.

The strength of attachment of fibers on any given area of any particular seed varied from about 0.25 to about 5.5 gm. The mean strength of fiber attachment varied from area to area on the seed. Fibers on the rounded (chalazal) end of the seed had the lowest strength of attachment and those on the pointed end the highest. A sample of 256 fibers on the side of a seed about half-way between the ends was considered a representative sample for a seed. For comparing 2 cottons, at least 10 or preferably 16 seeds, 1 from each of 10 or 16 bolls representing each cotton, are needed. Each seed is taken from the middle of the lock selected to represent the boll. Comparative tests of 41 selected cottons of different varieties and covering a wide range of seed-cotton characteristics showed that very significant differences exist between different varieties. Significant differences were apparent for cottons of the same staple length.

**Domestic flax: A report on its preparation and mill processing, H. BUNGER, J. L. TAYLOR, and C. A. JONES** (*Cotton, 105 (1941), No. 12, pp. 82-85, 126, figs. 8*).—Studies at the Georgia Engineering Experiment Station on adaptability of flax to the soil and climate of the South and the processing of flax straw into a fiber suitable for use on cotton mill equipment and for blending with cotton in textile products are reported. The Georgia Agricultural Experiment Station and the Tennessee Valley Authority were other participants in the flax program.

A pilot plant was constructed which could produce from 10 to 15 lb. of fiber an hour. All flax yarns could be spun on cotton equipment and woven into a fabric if the quality was good enough for cotton mill processing, but the quality of the fiber thus far produced in the pilot plant from retted or unretted flax straw was not suitable for practical spinning of 100-percent flax yarn on cotton equipment. Flax fiber might be blended with cotton and other fibers.

**The comparative winter hardiness of oat varieties, F. A. COFFMAN** (*U. S. Dept. Agr. Cir. 622 (1941), pp. 35, figs. 4*).—The uniform winter-hardiness nurseries of oat varieties, grown for 1 yr. or longer at each of 32 stations in the southern winter oats areas, 1927-36, included many varieties and a wide range of soil and climatic conditions. Differential killing occurred in 138 of 179 station years for which data were accumulated. In other cases complete or no killing occurred.

Hairy Culberson (C. I. 2505) survived best, on the average, and was followed by Bicknell, Culberson (C. I. 273), and Fulghum (winter type, C. I. 2499). Two typical strains of Winter Turf, formerly considered the hardiest winter oats, ranked fifth and seventh of 12 varieties grown in all tests. All the 4 hardy varieties surviving best probably resulted from hybrids between *Avena sativa* and *A. byzantina*. Markton, a nonhardy spring oats, when crossed with Red Rustproof produced hybrids hardier than Red Rustproof, although less hardy than certain other oats. Fulghum (winter type, Tennessee selection 090, C. I. 3175), tested for only a short period, appeared to be exceptionally hardy.

In the region in which winter oats are grown, killing in the nurseries was not of consequence in the mildest southern zone, where the average minimum winter temperature was 20° F. or above, seldom was serious in the 20° to 10° minimum temperature zone, often occurred in the 10° to 0° zone, and usually was severe and often complete in the northern zone, where the minimum temperature averaged 0° or below. Only the hardiest varieties could be expected to survive where the minimum winter temperature averages below 0°. Little information was provided on relative hardiness of varieties in the southernmost zone, where survival usually was complete, or in the northern zone, where all sorts often were killed.

The ranking of the oats varieties in hardiness at different stations and in different years was rather similar. In general, at corresponding absolute minimum temperatures, killing increased as the soils became progressively heavier. Killing was infrequent on any soil type when air temperatures remained above 15°, while below -5°, in the absence of snow covering, killing was usually severe or complete. No relation between winter survival and altitude was evident, except as altitude is related to temperature. Winter-killing appeared to be severer west of the Mississippi River than under comparable temperature conditions in the East.

**Potato breeding, genetics, and cytology: Review of literature, 1940,** F. J. STEVENSON. (U. S. D. A.). (*Amer. Potato Jour.*, 18 (1941), No. 11, pp. 317-329).—The review covers 39 titles published 1938-40.

**Influence of sprouts on plant emergence, growth, tuber-development, and yield of potatoes,** E. N. McCUBBIN. (Cornell Univ.). (*Amer. Potato Jour.*, 18 (1941), No. 6, pp. 163-174, figs. 3).—Plants of sprouted tubers of a strain of Smooth Rural potatoes came up first, desprouted tubers next, and dormant tubers last. Subsequent plant growth as measured by increase in plant height, blooming, time of tuber set, increase in weight of tubers, and time of maturity was in the order of emergence. The most stems per seed tuber were produced by desprouted tubers due to the desprouting operation. Sprouted tubers produced more stems per seed tuber than dormant tubers because of storage at the higher temperature. The most tubers per plant were produced by seed which had the most stems per plant. The final yield in weight of tubers from sprouted, desprouted, and dormant seed evidently would depend primarily on time of planting, length of growing season, and climatic conditions. With early planting, or a season long enough to permit plants to attain complete maturity, yields would no doubt be equal, while with late planting or a short growing season, in which the plants of all treatments were killed by frost before maturing, yields would probably be highest from sprouted and lowest from dormant seed. The relative response of the three types of seed was the same whether stored in light or in dark for 1 mo. before planting. Delay in emergence, subsequent growth, and maturity resulting from removal of short sprouts compared with no removal was caused by loss of the sprout as a plant part rather than to loss of food reserves or growth substances it contained.

**A test of the possibilities of photoperiodic induction of blooming in Triumph potatoes and the morphological consequences,** H. O. WEENER. (Nebr. Expt. Sta.). (*Amer. Potato Jour.*, 18 (1941), No. 5, pp. 144-149).—When early-strain Triumph potato plants were variously subjected to an 8-hr. photoperiod for from 1 to 5 weeks during the first 5 weeks after emergence and a 16-hr. photoperiod with supplemental light used at all other times, indications were that a long photoperiod of bright light is needed for longer than an induction period to obtain flowers and berries. Small vines and low yields of tubers followed use of short days during the first few weeks.

**Effect on berry production of varied day length during the life of two Triumph potato strains, II.** O. WERNER. (Nebr. Expt. Sta.). (*Amer. Potato Jour.*, 18 (1941), No. 6, pp. 174-178).—Plants of the Triumph potato strain intermediate in maturity grown during the winter with a 24-hr. photoperiod, with supplemental light of 200-250-footcandle intensity, bloomed and produced seed satisfactorily only if the long photoperiod was used for the first 60 or 70 days after plant emergence. Fewer berries were produced with an 18-hr. photoperiod. Long photoperiods for the initial 20-50 days, however, resulted in meager blooming. The earliest maturing strain produced fewer berries and only when the 24-hr. photoperiod was used for 40 days or longer before blooming.

**The influence of fertilizers on potato tuber shape.** K. C. WESTOVER. (W. Va. Expt. Sta.). (*Amer. Potato Jour.*, 18 (1941), No. 6, pp. 155-163).—Measurements of lengths and widths of Cobbler potatoes grown at Lakin, W. Va., 1933, 1936, and 1939 on Wheeling fine sandy loam variously fertilized, revealed that N and P affected length most and that K had little effect under unfavorable conditions but contributed more to width under favorable circumstances.

**Fertilizers for Oklahoma potatoes.** E. F. BURK (*Oklahoma Sta. Bul.* 249 (1941), pp. 42, figs. 8).—Experiments concerned with formulas and rates of fertilizers for potatoes were conducted from 1 to 5 yr. in eight localities, 1930-37. Results in general suggested a 4-12-4 mixture on the heavier soil types and a 6-12-6 on the lighter ones applied at acre rates of from 400 to 600 lb. As a rule, lighter applications of fertilizer usually should be made in the western and central parts of Oklahoma and heavier applications in the eastern section. The use of more K than N in the mixture was not indicated, although in general the sandier the soil the greater the need for N, and the greater the percentage of clay in the soil the less the need for K. The tests reported were in agreement with those at other stations which have shown a close relationship to exist between the amount and distribution of rainfall and responses of potatoes to N, P, and K, and that the amount and distribution of rainfall are important factors in determining both grade and total yield.

Besides recommendations of formulas and rates for different soil types, comments are made on factors affecting use of fertilizers, i. e., moisture supply, green manures, and organic v. inorganic N sources; relation between yield increase and grade; response of the crop to different nutrients; and suggestions on buying fertilizers.

**Growth habits of reed canary grass.** M. W. EVANS and J. E. ELY. (U. S. D. A. coop. Ohio Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 33 (1941), No. 11, pp. 1017-1027, figs. 3).—The underground rooting stems or rhizomes of reed canary grass (*Phalaris arundinacea*) originate chiefly during May, June, July, and August. Above-ground shoots develop in largest numbers during fall and early spring. In the latitude of northern Ohio culms, with their elongated internodes, begin to form about April 15. Shoots which begin growth in the spring and summer are not winter hardy and their life is limited to the same season. The life of a shoot which develops in the fall is limited to the growing season of the following year. In the latitude of northern Ohio, inflorescences begin to develop from the growing points of the shoots about April 15, flowering begins in early June, and seeds mature in late June and early July. Flowering and maturing gradually progress from just below the tip of the inflorescence toward its base. The leaves of reed canary grass are destroyed by temperatures not low enough to destroy the leaves of timothy, redtop, Kentucky bluegrass, and some other northern meadow and pasture grasses.

**This year's experiments with mechanical thinning of sugar beets show progress.** E. M. MERVINE. (Coop. U. S. D. A.). (*Colo. Farm Bul.* [Colorado

*Sta.*], 3 (1941), No. 4, pp. 6-8, fig. 1).—Yields of sugar beets mechanically thinned by a tractor-drawn thinning tool, supplemented by laborers using long-handled hoes, did not differ much from yields in a hand-thinned field, and the labor time was cut about in half and stoop labor eliminated. Development of the single-seed ball planter resulted in an improved type of planting with consequent increase in number of single beet plants and appreciable saving in seed. Results with this planter were still further improved when small seed were used.

**Management of sweet clover in a pasture system**, C. A. HELM (*Missouri Sta. Cir.* 215 (1941), pp. 10, figs. 2).—Sweetclover has an important place in the seasonal succession of Missouri pasture crops. Second-year sweetclover equals or surpasses all other crops for spring pasture, and first-year sweetclover, correctly managed, provides good pasture from October to December. The combined use of sweetclover and Korean lespedeza furnishes highly productive legume pastures in spring, summer, and fall. Practical information is given on the growth habits and soil requirements of sweetclover and on its cultural and grazing management in various combinations and sequences. Returns from good management of sweetclover and Korean lespedeza in combination to produce an all-season legume pasture are illustrated in results obtained, 1938-41, near Paris, Mo.

**La batata como cultivo sucesivo al algodón** [The sweetpotato as a crop to follow cotton], E. MOLINAR SALÉS (*Agr. Expt. [Puerto Rico Univ. Sta.]*, 1 (1941), No. 5, p. 6, fig. 1).—The sweetpotato, especially the Don Juan variety, is indicated as a good crop to follow sea-island cotton because of rapid growth and response to fertilizer residues left by the cotton. Since the sweetpotato belongs to a family unrelated to cotton, it would not be liable to introduce certain insects and diseases into the rotation.

**Birdsfoot trefoil and big trefoil**, R. McKEE and H. A. SCHOTH. (Coop. Oreg. Expt. Sta.). (*U. S. Dept. Agr. Cir.* 625 (1941), pp. 14, figs. 4).—The general characteristics of birdsfoot trefoil (*Lotus corniculatus*) and big trefoil (*L. uliginosus*) and their soil and climatic requirements are described. Comments are made on forage and pasture value, seed, and insect pests, and practices are indicated for growing and harvesting the crop for forage and seed. Descriptions and keys give the specific characters that separate species, varieties, and forms and indicate the range of variation. The limited experience with both plants in the United States follows the pattern of experience in Europe, Australia, and New Zealand, indicating that these plants are adapted to at least limited sections and usable for forage and pasturage.

**Protein surveys of American hard spring and soft winter wheats**, C. H. BAILEY (*Minnesota Sta. Tech. Bul.* 147 (1941), pp. [1]+46, figs. 25).—The distribution curves of protein content of 14 crops of hard spring wheat marketed through Minneapolis from 1925-26 to 1938-39 showed that, in general, protein content tends to increase in progressing from east to west in the spring wheat area, although not in all seasons. Variability in protein content of spring wheat was not uniform from season to season. As measured as standard deviation, it was greatest in 1935 and 1936, the seasons of highest average protein content, and lowest in 1927 and 1928, seasons of the lowest protein content. Although rainfall appeared prominent among climatic factors influencing the protein content of a crop, correlation between rainfall and average protein content was not perfect, since there was a carry-over of the effect of previous seasons. Dark northern spring wheat had a higher average protein content than northern spring in the seasons 1933-36, when subclass comparisons were made.

The variability of individual shipments from a single shipping point was measured, and the standard deviation of the coefficient of variation of an aver-

age of 161 shipping points per season for four seasons was 1.14, i. e., chances are even that a single shipment would fall within  $\pm 1.14$  percent of the average protein content for the station. Protein premiums appeared to be a function of the percentage of the crop which contained more than 13 percent of protein. The relation between these two variables is expressed graphically as an exponential curve, resolvable into a straight line by using the equation  $\log(y-c)=x$ , in which  $y$  equals percentage of crop containing more than 13 percent protein,  $x$  equals protein premium in cents per bushel per 1 percent protein, and  $c$  equals a constant, which proved to be 4.

Soft red winter and white wheats, grown chiefly in Illinois, Indiana, Ohio, and Michigan during the crop seasons of 1931-32 to 1937-38, contained a lower average percentage of protein than the hard spring wheats harvested during the same seasons. Variability in the protein content of the samples of soft red winter wheat was only about half as great as that among hard spring wheats.

Brief reviews of research on the influence of environment on the composition of wheat and of the relationships between kernel texture and protein content are included.

**Proceedings of the Association of Official Seed Analysts of North America, 1940** (*Assoc. Off. Seed Anal. North Amer. Proc.*, 32 (1940), pp. 105+[2], figs. 19).—Papers presented at the thirty-second annual meeting at Auburn, Ala., June 18-21, 1940, included The Viability of Injured Weed Seeds (pp. 31-42)—The Plant Producing Value of Injured Seeds of *Rumex* spp., by L. A. Kanipe (pp. 32-39) (Oreg. Expt. Sta.), Summary Report of Three Years Work, by V. J. Thompson (pp. 40-41) (Iowa Sta.), and *Ambrosia artemisiifolia* and *Setaria viridis*, by A. C. Heise (pp. 41-42); The Iowa Experimental Method for Purity Analysis of *Chalcis*-Fly Infested Red Clover and Alfalfa Seeds, by W. A. Robbins (pp. 46-49), and Our Responsibilities as an Association, by R. H. Porter (pp. 62-69) (both Iowa Sta.); Some Problems in the Analysis of *Chalcis*-Fly Infested Red Clover and Alfalfa Seed, by P. Hayes (pp. 49-52), and Separation of Immature Seeds of *Trifolium repens*—White Clover, and *Trifolium hybridum*—Alsike Clover, by M. Weisner (pp. 103-105) (both Oreg. Sta.); Proposed Changes in the Rules and Recommendations for Testing Seeds as Regards the Disposition of Insect-Damaged Seeds, by J. S. Jones (pp. 52-54); Reactions to the Federal Seed Act and Some Observations for the Improvement of Seed Conditions in the South, by R. E. Lambert (pp. 70-73); Increasing and Renewing Seed Stocks in One-Variety Cotton Communities, by R. R. Childs (pp. 73-75) (Ga. Sta., U. S. D. A., et al.); The Quality of Seed Farmers Grow and Plant—A Seeder Survey, by L. E. Everson (pp. 75-77), A Method for Quickly Determining the Pure Seed Content of Bluegrasses, by B. Cullinan (pp. 81-83), Influence of Phytohormones on Germination and Growth of Cereals, by W. Crosier, S. Patrick, and D. Weimer (pp. 83-86), Response of Germinants From Beans, Corn, and Peas to Seed Treatments With Hormones and Mercurials, by W. Crosier and C. E. Heit (pp. 88-92), and Do We Need Flower Seed Germination Standards? by M. T. Munn (pp. 102-103) (all N. Y. State Sta.); An Experiment in Mixing and Sampling Kentucky Bluegrass, by W. A. Price and E. C. Vaughn (pp. 77-80) (Univ. Ky.); The Evaluation of Hard Seed in Annual Lespedezas When the Germination Test Is Made Soon After Harvest, by J. W. Woodside (pp. 86-88); and The Effect of Light and Temperature on the Dormancy of Scotch Pine Seed, by E. J. Eliason and C. E. Heit (pp. 92-102) (N. Y. State Sta. et al.).

Technical problems were also considered in committee reports.

**[Seed and inoculant research]** (*Farm Res. [New York State Sta.]*, 8 (1942), No. 1, pp. 1-2, 4-5, 8, 15, figs. 2).—Legume Inoculant Tests for 1941, by A. W. Hofer (pp. 1, 15), discusses and tabulates results of tests of 64 commercial

legume inoculants on sale in New York. Control Field Plantings Verify Variety Names (p. 2) reports on variations in trueness to type and variety in 320 samples of field crop seed, 509 of vegetable, and 63 samples of flower seed tested in control fields. Seed Testing Combines Both Service and Research (pp. 4-5) reviews the activities of the seed testing laboratory during 1940-41. The decided superiority of the wild white or permanent pasture types of white clover is noted briefly.

**Farmstead weeds**, A. H. LARSON, L. ERICKSON, and R. B. HARVEY. (Minn. Expt. Sta.). (*Seed Trade Buyers Guide*, 24 (1941), pp. 65-70, 73-82, figs. 15).—Popular descriptions with illustrations and control methods are given for common farm weeds.

**Representative Missouri weeds and their control**, W. B. DREW and C. A. HELM (*Missouri Sta. Bul.* 433 (1941), pp. 211+[5], figs. 89).—A practical manual discussing in nontechnical terms the economic importance of weeds and methods for their control, and providing determinative keys for the principal groups and for individual weeds and descriptions, including distribution and control methods of representative weeds. A brief glossary and indexes to common and scientific names are included.

**Weeds of New Jersey**, J. G. FISKE (*New Jersey Stat. Cir.* 416 (1941), pp. 51, figs. 35).—This revision of Circular 219 (E. S. R., 62, p. 523) is concerned with common, noxious, and lawn weeds and their control by the most recent methods.

**Thistles, wormwoods, and ragweeds in North Dakota**, O. A. STEVENS (*North Dakota Sta. Bimo. Bul.*, 4 (1941), No. 2, pp. 10-12, figs. 3).—The occurrence, and in certain cases the economic importance, of true thistle (*Cirsium* spp.) and related plants, wormwoods (*Artemisia* spp.), and ragweeds (*Ambrosia* spp.) in North Dakota are described briefly.

## HORTICULTURE

[**Horticultural studies by the Alabama Station**] (*Alabama Sta. Rpt.* 1940, pp. 32-39, 40-41).—Information is presented on the progress of the following investigations: Comparative cold resistance of several cabbage, collard, and English pea varieties in the field during the winter of 1939-40 and a comparison of outstanding lines of pole snap beans developed by the station and of several commercial varieties, both by F. E. Johnstone, Jr.; the influence of several plant hormones on the rooting of some ornamental plants, by E. W. McElwee; and the possibilities of devil's shoestring (*Tephrosia virginiana*) as a hillculture crop, by O. A. Atkins.

[**Horticultural studies by the Colorado Station**] (*Colorado Sta. Rpt.* 1941, pp. 31, 32-33).—Brief statements are presented on the progress of investigations in onion breeding and fertilization, fertilization and mulching of sour cherries, variety tests of fruits, factors involved in winter injury on raspberries, and the nutritional requirements of the carnation.

**Propagation of plants**, L. R. BRYANT and G. BEACH (*Colorado Sta. Bul.* 468 (1941), pp. 26, figs. 10).—This general bulletin discusses the technics of increasing plants by means of seed and by the use of vegetative portions, such as scions, buds, cuttings, layers, tubers, bulbs, corms, divisions of the crown, etc. The use of growth-promoting substances is considered, and the tools and materials required in grafting and budding operations are described.

**Effects of synthetic growth substances on transplants**, J. C. SWARTLEY. (Ohio State Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 357-360).—Treatments with synthetic growth substances stimulated root and stem development in woody plants, such as crabapples and Pfitzer juniper; in perennials,

such as coreopsis; and in annuals, such as the tomato and aster. Talc mixtures of certain growth substances applied to the moistened roots of small trees caused the development of abnormal clusters of branch roots. The watering of grafted stocks with solutions of synthetic substances resulted in increased survival and more rapid development of absorption roots, particularly in red cedar.

**Grouping of strains or varieties by use of a Latin square**, W. D. BATES, J. I. NORTHAM, and A. F. YEAGER. (Mich. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 33 (1941), No. 7, pp. 616-632).—This paper describes a lay-out of 61 strains of tomatoes in groups of 16, planted in a 4 x 4 Latin square, and contains statistical analyses pertaining to the yields of these strains. Techniques are presented for arriving at valid experimental errors when certain error variances are heterogeneous, and tests are given for comparing the mean of groups, the means of strains within a group, and the means of strains in different groups. A statistical analysis is given when estimates are made for certain extraordinary plot yields.

**"Starter" solutions in the production of cauliflower and brussels sprouts on Long Island**, W. C. JACOB and R. H. WHITE-STEVENS. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 349-350).—None of eight starter solutions, supplied at the time of setting at the rate of about 1 pt. per plant to cauliflower grown on an area receiving 1 ton of 4-8-6 fertilizer per acre plus a side dressing of 125 lb. of nitrate of soda, exceeded water in value. In another trial with cauliflower and brussels sprouts, also on a heavily fertilized soil, no benefit was obtained from starter solutions with or without added growth-promoting substances, such as indoleacetic acid. Any response that attained significance was in a harmful direction. It is suggested that the high level of fertility under which the crops were grown may have been a factor in the results.

**Studies of the response of lettuce to manure and commercial fertilizers**, A. E. GRIFFITHS. (Univ. Ariz.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 351-356, fig. 1).—Of various fertilizers applied in bands at the time of setting lettuce (September 12) on an area given 10 tons per acre of partially decomposed manure before planting, ammonium phosphate (11-48) gave the highest yields. On the same soil without manure, the highest yields were obtained from an experimental mixture of approximately 9-26 analysis, with one-fourth of the N from blood meal. In general, simple inorganic materials gave the best results on the manured soil and fertilizers with a part of the N from organic sources on the unmanured soil. The manure resulted in more rapid growth, earlier maturity, and a more succulent plant. In general, lettuce from manured plots contained more N and P at harvest than that from nonmanured plots. Water penetration into the soil was more rapid and uniform and soil moisture was higher preceding irrigation on the manured areas.

**Quality of muskmelons as related to condition of plants**, J. D. HARTMAN and F. C. GAYLORD. (Purdue Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 341-345).—Available leaf area and freedom of leaves from disease had an important effect on soluble solids content and quality of ripe melons. Refractive indices, as determined by the Abbe apparatus in 1939 and the Zeiss in 1940, were useful indicators of quality, but were not closely enough correlated with taste to be used blindly as measures of edible quality. In 1939 the simple correlation coefficient for the taste estimate and soluble solids was  $0.62 \pm 0.02$  and in 1940,  $0.53 \pm 0.02$ . Other factors, especially the amount of aromatic substances, may influence edibility ratings. Variations in ripeness among melons picked supposedly when fully ripe may affect soluble solids content.

**A study of natural crossing in peppers (*Capsicum frutescens*),** M. L. ODLAND and A. M. PORTER. (Univ. Conn.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 585-588).—Interplantings of varieties with contrasting characters, such as fruit color or shape, showed considerable natural crossing in the cultivated pepper. The amount of intercrossing varied with varieties, and there was as much crossing between varieties of different groups as among varieties of a single group. No variety was entirely self-fertilized. The honeybee was observed on pepper flowers and is believed to be largely responsible for cross-pollination. Wind may carry pollen to nearby plants, but it is thought to cause little, if any, of the crossing observed.

**Comparative earliness and productiveness of first and second generation summer squash (*Cucurbita pepo*) and the possibilities of using the second generation seed for commercial planting,** L. C. CURTIS. (Conn. [New Haven] Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 596-598).—Continuing the earlier-noted study (E. S. R., 84, p. 187), in 1940 Early Prolific Straight Neck, Connecticut Straight Neck No. 10, and the  $F_1$  and  $F_2$  from a cross of the two were compared in a Latin-square design as to earliness and yield. Neither total yield nor early yield was reduced materially in the  $F_2$  generation. The  $F_2$  would have the material advantage of reduced cost of seed production since no emasculation or hand-pollination would be required. Since summer squash is harvested in an immature state, variability in size and form is minimized in importance. A possible further advantage for the  $F_2$  was that segregation for earliness resulted in 2.4 percent of the plants producing female flowers 2 days before such appeared in the  $F_1$  generation.

**Some new sweet corn varieties for New York growers,** W. D. ENZIE (*Farm Res. [New York State Sta.]*, 8 (1942), No. 1, pp. 7, 9).—Information is presented on yields, days to maturity, average length of ears, number of rows of kernels per ear, and percentage of usable raw product for five yellow and six white hybrids. Allegheny, a yellow hybrid sweet corn, yielded at the rate of 7.98 tons per acre in 1941, but was inferior to Golden Cross in sweetness and flavor.

**A preliminary report on two plants versus one tomato plant per stake,** E. P. BRASHER. (W. Va. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 329-331).—Break o'Day tomato plants were grown one and two per stake set 2 ft. apart in rows 4 ft. apart. The yield of early marketable fruit was 8.84 tons per acre for the two and 6.48 tons for the single plants. Total yields were 15.58 and 10.68 tons, respectively. The size of fruits was slightly larger on the single plants but not enough to offset the additional numbers on the double plants. In a variety such as Break o'Day, the increased foliage of the double plantings is conceded of potential value in protecting fruits from sunscald.

**The efficient use of nitrogen in tomato culture,** J. B. HESTER (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 308-312).—That large contents of nitrogen in the commercial fertilizer mixed in the row prior to planting may not only be ineffective but actually decrease yields of tomatoes was indicated in experiments in New Jersey and Pennsylvania in 1939 and 1940. Evidence was obtained that on Sassafra soil the application of nutrient materials as side dressings about 2 and 7 weeks after planting was an efficient method. Tomatoes fertilized in the row prior to planting appeared to be overvegetative, and the amount of nitrogen in the leaves supported this observation. In the case of tomatoes supplied with superphosphate and side dressed with different materials, cyanamide broadcast at the rates of 100, 200, 400, and 600 lb. prior to planting had no benefit on Sassafra sandy loam. On the Collington fine

sand 200 lb. of cyanamide gave the largest increase in yield. Studies of the effect of applied nitrogen on the quality of tomatoes showed no significant difference except a slight increase in the nitrogen content of the fruit.

**A 5-year yield record of tomato varieties for canning, W. T. TAPLEY** (*Farm Res. [New York State Sta.], 8 (1942), No. 1, pp. 3, 12*).—Data are presented on the total, early season, midseason, and late season yields of nine varieties or strains of tomatoes which thrived well in western and up-State New York. The total yields, averaged for the 1937–41 period, ranged from 13.82 tons per acre for Stokesdale to 10.17 tons for Marglobe. Geneva John Baer led in early yields but was closely followed by Stokesdale.

**Relation between soil organic matter and available moisture under different orchard cultural systems, L. HAVIS.** (Ohio Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc., 38 (1941), pp. 32–36*).—Studies of soil samples collected in July and August from sod, mulch, and cultivation plats in a 25-year-old apple orchard showed considerably less organic matter under cultivation, even though cover crops had been grown. In one location the mulch and sod samples were about equal in organic matter, and in another the mulch was significantly higher than the sod. The moisture equivalents increased with the organic matter percentage at each location, and the mean wilting percentages varied directly with organic matter although not significantly in all instances. Available moisture percentage computed by determining the difference between wilting percentage and the moisture equivalent was higher under mulch and sod than under cultivation. The differences in organic matter due to cultural treatments resulted in significant differences in available moisture.

**The first twenty years results in a Michigan apple orchard: Cultivation-covercrop vs. sod-mulch culture, W. TOENJES** (*Michigan Sta. Spec. Bul. 313 (1941), pp. 18, figs. 5*).—In an orchard established at the Graham Horticultural Substation near Grand Rapids in 1919, one-half of the trees were maintained under the cultivation-cover crop system and the other half under clover sod-straw mulch. However, the clover was soon crowded out by bluegrass, which was mowed and placed under the trees. Additional materials, such as straw, damaged hay, and weeds, were added to the mulch from time to time. Nitrogen fertilizers were applied annually in equal amounts to both areas.

During the first 10-yr. period the trees under clean culture made the larger trunk growth and produced more fruit per acre, but at the close of 20 yr. the trees in sod-mulch were larger and had produced the greater acre yields. The fruit from the mulched trees had slightly more color and graded out approximately 79 percent more grade A-sized apples than did fruit from the tilled areas. The annual acre cost of maintenance was about the same, being slightly less for the sod-mulch treatment. The soft, spongy nature of the mulch reduced the damage to dropped apples, but mulches provided winter quarters for mice and increased the hazard of girdling injury. Fire was also a greater menace in the mulched area. Clean cultivation favored erosion with exposure of roots to cultivation and low-temperature injury. During a dry period in late summer there was much more moisture in the soil beneath mulch than beneath cultivation-cover crops. The author suggests that the change from cultivation-cover crop system to mulching might be made at an earlier stage than is usually practiced. The type of procedure will vary with soil fertility, depth of soil, and slope in the orchard.

**The effect of soil-management methods on certain physical and chemical properties in relation to the infiltration rates in West Virginia orchards, R. H. SUDDS and G. M. BROWNING.** (W. Va. Expt. Sta. coop. U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc., 39 (1941), pp. 38–46, fig. 1*).—Observations on a

total of 63 profile samples taken from 20 commercial orchards showed that cultivation as compared with an undisturbed sod cover had reduced the organic matter content, the percentage of the larger aggregates, the noncapillary porosity, and the infiltration rates, but had increased the volume weight and the dispersion ratio. Straw mulch, by protecting the surface from the dispersing action of the water from the infiltrometer nozzles, materially increased the infiltration rate over that of tilled areas. The importance of protecting the surface with vegetation or ample mulches was indicated. Orchards in sod continuously maintained favorable structural conditions unless compacted mechanically.

**The correlation of trunk circumference with weight of top in some double-worked apple trees, F. N. HEWITSON.** (Mich. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 233-236).—"A group of Steele trees were cut off at the union of scion and interstock, or scion and seedling, according to the build-up of the tree, and the tops weighed. The weights of these tops were then correlated with the trunk circumferences and areas of trunk cross section. The coefficients of correlation were, respectively,  $0.910 \pm 0.018$  and  $0.921 \pm 0.016$ . By means of a regression equation based on all the trees in this experiment, it was possible to estimate weight of top from trunk circumference measurements to within 16 percent."

**Apple varieties and important producing sections of the United States, J. R. MAGNESS** (*U. S. Dept. Agr., Farmers' Bul. 1883* (1941), pp. II+32, figs. 5).—The development of the apple industry in the United States is traced, with information on the present distribution, numbers of trees, and production, together with specific information as to the important climatic and topographic features of the main apple sections. The insect and disease problems in the various areas are discussed, and the characteristics of the leading varieties of apples grown are described. Some consideration is given to color strains.

**Leaf analysis and apparent response to potassium in some prune and apple orchards.—Preliminary report, D. BOYNTON, W. REUTHER, and J. C. CAIN.** (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 17-20, figs. 2).—Studies in four prune and two apple orchards, the trees of which were initially low in K and showed varying degrees of leaf scorch, indicated that applications of K salts and of heavy manure mulches tended to decrease scorch and to increase the percentage of K in the leaves. The increase in K content was proportional to the amount of K applied to the soil. The only instance of a complete disappearance of scorch was in the case of 6-yr. Italian prunes receiving both manure and K salts. It is suggested that there may be a lag in the effectiveness of the K, due perhaps to internal conditions in the tree. The normal K content of prune leaves was apparently above that of apple leaves, and deficiency symptoms were evident in the prune at a higher K level.

**The nitrogen, phosphorus, and potassium content of peach leaves as influenced by soil treatments, J. G. WAUGH and F. P. CULLINAN.** (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 13-16).—Samples of leaves collected from Elberta trees in their ninth season in an orchard located on Sassafras gravelly loam and fertilized in April with potassium nitrate were found in most cases to have twice the K content of leaves from trees receiving an equivalent amount of N but no K. The leaves of K-deficient trees were smaller and slightly lighter in color. P and N values showed no marked difference between plats and no significant relation to K. Growth records indicated that trees supplied adequately with K had a much greater leaf area, made greater total growth, and formed more blossom buds per linear

foot of shoots. When certain 8- and 4-year-old trees were supplied with potassium sulfate on May 10 and June 12, respectively, by the end of July both lots of trees had three times and by September 3 four times as much K as did the controls.

**Certain factors influencing the size of dried prunes, A. H. HENDRICKSON and F. J. VEIHMEYER.** (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 80-85, fig. 1).—Over an 8-yr. period, French prune trees at Davis, Calif., produced approximately equal percentages of medium-sized dried prunes whether irrigated or not. The weights of small-sized prunes increased with the numbers of prunes on the trees in both the irrigated and dry plats. The weights of small sizes in the dry plats were further increased by the lack of readily available soil moisture during the growing season. The weights of medium-sized prunes in the irrigated plats increased also with the numbers of fruits on the trees. On the other hand, the weights of large prunes in the irrigated plats did not show a close or consistent relationship with the numbers of fruits on the trees. With prune trees which did not suffer for water during the growing season, the weights of the various sizes of dried fruits were largely determined by the amount of crop. A lack of available moisture during the growing season increased the weights of the small sizes, decreased the weights of large sizes, but had little effect on the weights of medium sizes.

**Fruit pressure testers and their practical applications, M. H. HALLER** (U. S. Dept. Agr. Cir. 627 (1941), pp. 22, figs. 2).—The construction and operation of various types of fruit pressure testers, designed to measure the firmness of fruit, are described. With advancing maturity, there is a decrease in firmness, but various factors such as temperature, moisture content of the fruit, methods of soil fertilization, soil moisture, fruit thinning, and rootstocks may influence the readings. Pressure tests offer a fairly accurate guide to ripeness of apples, particularly for indicating when fruit are becoming too soft and overmature for storage. Data are presented on the pressure-test range, representing different degrees of ripeness of a number of important apple varieties. With pears, the pressure test was found of primary importance for establishing picking maturity standards, and such standards are presented for a number of varieties. The pressure test has not proved as satisfactory as a measure of ripeness of pears during cold storage. With peaches and plums the test may be used to establish color standards for picking.

**Influence of spacing on yield and grade of strawberries, E. P. CHRISTOPHER** (*Rhode Island Sta. Bul.* 283 (1941), pp. 15, figs. 4).—Two spacing experiments were conducted, one beginning in 1936 and the other in 1937. Two varieties were used, Howard 17 and Dorsett. There was a total of 14 treatments, including mother plants set 18, 24, 30, and 36 in. apart in rows 3 ft. apart and runner plants ranging from matted rows with no limitations to five per mother plant. Under favorable growing conditions without runner control, both varieties tended to produce excessive numbers of runner plants. Spacing runner plants 5 to 7 in. apart resulted in the highest yields. Beyond 8 in., yields were reduced. Runner plants developed more and larger leaves as the distance between them was increased. The early-developing runners attained the largest size. Spacing did not materially increase the number of large berries, except as it increased total yields. Under moist, foggy conditions Howard 17 berries rotted more quickly than did Dorsett berries. For Rhode Island, it is concluded that mother plants should be spaced 18 to 24 in., with the runners about 6 in. apart.

**Relationship of width of thinned row to productiveness and quality in the Blakemore strawberry, J. C. CRANE and I. C. HAUT.** (Md. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 417-419).—Blakemore plants grown

in rows 10, 20, 30, and 40 in. apart with much the same spacing, 4 to 6 in., in the row yielded 15,635, 13,997, 12,418, and 10,632 qt. per acre. The percentage of U. S. No. 1 berries was about the same in all four arrangements. Despite the fact that the distance between plants was least in the 10-in. rows, these outyielded those in the wider rows on a plant basis. This result was explained by the fact that the 10-in. row included a greater proportion of early-formed and early-established runners, with a higher fruiting capacity.

**The pattern of strawberry root development under the matted and thinned row.** A. L. SCHRADER. (Univ. Md.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 413-416, figs. 2).—Studies by the soil-cube method of root distribution of Blakemore strawberry plants grown in matted rows and spaced 7 and 11 in. apart showed in all three cases the largest concentration of roots in the upper 3 in. of soil. The matted-row plants developed more roots, especially in the upper soil layers, than did the spaced plants. The roots of the spaced plants did not occupy fully the entire soil zone between plants but did develop a greater percentage of roots in the lower soil layers than did the matted-row plants. Comparing observations in September and the following April, it was evident that a great increase in root development occurred in this period. More roots developed during this time at deeper depths under the spaced than under matted-row plants. Root concentration under the matted plants may be partially responsible for the smaller fruit size.

**Fall setting strawberries in Missouri.** A. D. HIBBARD and T. J. TALBERT. (Mo. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 427-429).—Observations on the growth and development of strawberry plants set out at 15-day intervals, November 1 to December 2 and February 15 to April 15, showed greater runner production in the fall-set plants, and the young plants were larger because of their earlier establishment. Fall-set plants were less influenced by date of setting than were spring-set plants. Aroma plants set on November 15 were much more productive than those set March 15, sufficiently so as to warrant the additional costs incurred through mulching and extra cultivation.

**The Rocky Mountain strawberry as a source of hardiness.** A. C. HILDBRETH and L. POWERS. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 410-412).—Located in a region of extremely low winter temperatures, limited snow cover, and a highly alkaline soil, the Horticultural Field Station at Cheyenne, Wyo., found that the usual commercial strawberry varieties suffered severe injury. Selections of wild strawberries from the Rocky Mountain area were assembled and, although highly variable in plant and fruit characters, tolerance to alkalinity, etc., some showed considerable resistance to drought and all proved winter hardy without protection. Most of the material was apparently of the *Fragaria cuneifolia* type, with some *F. vesca* present. Crosses made between Gem, Dorsett, and Fairfax and selections of *F. cuneifolia* yielded  $F_1$  plants which in general were superior to the horticultural parents in winter hardiness. The  $F_1$  plants and their native parents were in general better plant makers than the horticultural parents. There was a great range in fruit size from that of the native parent to approximate Fairfax size. Seedlings with Fairfax and Dorsett parents were superior in flavor and sweetness to Gem seedlings. One seedling with Fairfax parentage produced highly aromatic, superior-flavored fruit. There was some variation in the time of flowering and fruit maturity. In a few cases  $F_1$  plants bloomed and ripened fruits earlier than either parent. Both spring fruiting and everbearers were obtained in all three crosses. The  $F_1$  hybrids set seed readily when selfed, backcrossed to either parent, or crossed with other  $F_1$  seedlings.

**Commercial strawberry culture in Missouri**, T. J. TALBERT and A. D. HIBBARD (*Missouri Sta. Cir.* 216 (1941), pp. 24, figs. 10).—General information is offered on the selection of sites, preparation of soil, rotations, varieties, planting, culture, fertilization, mulching, harvesting, marketing, control of insect and disease pests, etc.

**The rooting response of various species of *Rubus* to conventional methods of propagation**, L. E. JOLEY and A. W. CLOSE (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 420-423).—Information is presented on the results of propagation trials with a considerable number of *Rubus* species obtained from Europe and Asia. It was evident that raspberry species which propagate from suckers propagate poorly, if at all, from the canes. In limited trials with root-inducing substances, the greatest stimulation was obtained in those species that root without treatment. Applied as a dust in talc, indolebutyric acid increased rooting in a few instances and was harmful in others. A 1 : 1,000 dust of 3 parts of naphthaleneacetic acid plus 1 part each of thiourea and nicotinic acid increased rooting of one species and had no effect in another. Information is given on seed germination of certain species.

**Breeding autumn-fruiting raspberries under Oregon conditions**, G. F. WALDO and G. M. DARROW (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 274-278).—At Corvallis, Ore., the cross Lloyd George × Ranere yielded a high percentage of early autumn-fruiting seedlings and the cross Cuthbert × Lloyd George a large percentage of midautumn-fruiting seedlings. The early-maturing autumn-fruiting seedlings of Cuthbert × Lloyd George, although few in number, contained the more promising selections for commercial use. There were so few early fall-fruiting seedlings in the Viking × Lloyd George and Newburgh × Lloyd George crosses as to render these crosses ineffective. Similar observations were made on crosses of Lloyd George × Chief, Latham, Potomac, U. S. No. 231, and Plum Farmer. Selling a variety was apparently an effective method for determining its value as a source of fall-fruiting seedlings. Lloyd George, the best parent of fall-fruiting seedlings, was most productive of such material when crossed with a variety tending toward fall fruitfulness. There was a tendency for more seedlings of Lloyd George × Ranere to fruit in the autumn in Oregon than in Maryland.

**Production, berry size, and growth of red raspberries as influenced by mulching**, W. H. CHILDS (W. Va. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 405-409).—Heavy mulching with rye, buckwheat, and wheat straw of Latham, Chief, Viking, and Newburgh red raspberries proved superior to cultivation, whether evaluated by total yields or by wood production. The increase in yields was statistically significant in two cases, doubtfully so in a third, and not significant in others. Wood production, as measured by weight of postharvest pruning, was highly correlated with yield in most instances. In one of the two seasons increased berry size was a factor in increased yields. Mulching delayed ripening slightly and is deemed particularly valuable on soils subject to erosion and where the moisture supply is limited.

**Yield, size of berries, and season of maturity of the highbush blueberry as influenced by severity of pruning**, W. T. BRIGHTWELL (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 447-450).—Measurement of blueberries collected from plants pruned to various degrees of severity from none to heavy showed, in general, that the average size of berries increased with the severity of the pruning. Total yields decreased, in general, with severity of pruning, and there was a tendency for the severely pruned plants to mature a larger percentage of their fruits earlier in the season. The amount of rainfall during the growing season modified the effects of pruning. Large laterals

matured their fruits earlier than small laterals, and this fact may explain why the heavily pruned plants tended to ripen more of their crop early.

**Leaf characters as a basis for the classification of blueberry varieties,** J. H. CLARK. (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 441-446, fig. 1).—A device, designated as the New Jersey Blueberry Leaf Gauge, and found useful in the rapid measurement of blueberry leaves, is described. Measurements of leaves before and after drying in a press showed but little change, suggesting that either measurement would be satisfactory in classification. Rubel leaves collected from several parts of the State varied somewhat, yet the measurements were close enough to be of value in classification. A preliminary grouping of blueberry varieties based on leaf characters is presented.

**The relationship of different methods of expressing size of blueberry fruits,** F. B. CHANDLER. (Maine Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 279-280, fig. 1).—A study in 1939 and 1940 of the distribution of 11,710 blueberry diameters showed them to form a normal curve. When the data for samples with the same mode were combined and the curves for each group plotted, they were found to be very similar. The correlation coefficient of the mean diameter of all the berries and the diameter of the largest berry was  $+0.712 \pm 0.040$ . The correlation coefficient of the mean diameter of all the berries and the mean diameter of a 3-percent sample including the largest berries was  $0.793 \pm 0.030$ . When the number of berries per cup and the mean diameter of the berries were plotted, the relationship was curvilinear. When the data were analyzed the correlation index for curvilinear relationship was  $0.9997 \pm 0.0001$  in 1939 and  $0.9912 \pm 0.003$  in 1940. The correlation index for the number of berries per cup and a 3-percent sample including large berries was  $0.8816 \pm 0.038$ .

**Studies on the shatter of grapes, with special reference to the use of solutions of naphthalene acetic acid to prevent it,** W. T. PENTZER. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 397-399).—Clusters of four vinifera varieties of grapes (Sultanina, Flame Tokay, Alphonse Lavallec=Ribier, and Emperor), one labrusca (Pierce), and one muscadine (James) were treated with solutions of naphthaleneacetic acid. Whether applied as a preharvest spray or as a dip to freshly picked grapes, the chemical failed to increase berry adherence in any case. There was a marked natural difference among varieties in the strength of berry attachment. Ribier and Emperor, characterized by tough skin and well-developed pedicels, were three to four times as strongly attached as Sultanina.

**The Brunswick (Magnolia) fig,** I. J. CONDIT. (Calif. Citrus Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 143-146).—Based on a study of the literature and of trees and fruit, the author concludes that the Magnolia fig is identical with the older variety Brunswick.

**Interesting minor fruits for New York gardens,** G. L. SLATE (*Farm Res. [New York State Sta.]*, 8 (1942), No. 1, pp. 11-12, fig. 1).—Discussed as to habitat, growth and fruit characters, and horticultural possibilities are the following species: American persimmon, papaw, juneberry, buffaloberry, elderberry, high bush cranberry, Chinese bush or Nanking cherry, and western sand or Bessey cherry.

**Periodicity in transpiration of lemon cuttings under constant environmental conditions,** J. B. BIALE. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 70-74, figs. 2).—After a preliminary period in a uniform environment, Eureka lemon cuttings with four or five leaves were placed in sealed jars containing nutrient solutions and exposed in a control chamber to 4-hr. photoperiods alternating with 4 hr. of darkness. Measurements of water loss by transpiration showed a pronounced drop during the lighted hours from

midnight to 4 a. m. The maximum transpiration values were obtained for the same period by reversing the preliminary light exposure, that is, providing an artificial day from 8 p. m. to 8 a. m. This inversion was brought about by only 9 days of exposure. The observed periodicity was most pronounced during the first 3 or 4 days following change of conditions.

**Effect of planting date on germination of tung nuts in the nursery, S. MERRILL, JR., W. A. SLICK, J. H. PAINTER, and R. T. BROWN. (U. S. D. A.).** (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 153-156, figs. 2).—Open-pollinated fruits, saved separately from each of 20 tung trees, were stored as whole fruit in the loft of an unheated garage where the temperature fluctuated widely. A total of 16 plantings was made at intervals from December 5 to July 3, and emergence records were taken beginning May 6. The best results, 72-78 percent, were obtained in the five plantings made between February 20 and April 10. In general, germination fell off rapidly in plantings made later than April 10, and only a few trees large enough for budding or satisfactory transplanting were obtained in plantings made after that date. There was a large difference in the germinating capacity of different lots, due in part to environmental factors and in part to inherent characteristics.

**Period of stigma receptivity in flowers of the tung tree, R. T. BROWN and E. FISHER. (U. S. D. A.).** (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 164-166).—Controlled pollinations made in a tung orchard near Cairo, Ga., showed that pistillate flowers remained receptive for about 9 days after the corolla had opened. There was a trend for fewer nuts to be produced per flower in pollinations made after the corolla had been open 5 days or longer, but the difference was not significant until the eighth or ninth day. Similar work at Gainesville, Fla., showed similar results. In the Cairo study, no evidence of self-incompatibility was seen in any of the eight trees used.

**The growth period in shoots and fruits of mature tung trees, W. W. KILBY and M. D. PARKER. (U. S. D. A.).** (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 161-163, figs. 2).—Measurements taken at weekly intervals from April 17 to July 24 on fifteen 7-year-old tung trees in a well-cared-for Mississippi orchard showed shoot elongation to take place in the period April 17 to about July 18. The most rapid growth was recorded between April 26 and June 6. The duration of the growth period was the same for all shoots, irrespective of their ultimate length. Measurements of fruit on the same branches showed that the growth period of the nuts coincided exactly with that of the shoots, the shape of the curve being of the general sigmoid type. There was no period of arrested development.

**Preliminary experiments on the resistance of the tung tree to low temperature, D. L. FERNHOLZ and G. F. POTTER. (U. S. D. A.).** (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 167-172, fig. 1).—Artificial freezing tests conducted in an insulated chamber capable of producing temperatures down to about  $-10^{\circ}$  F. showed that the tissue of tung trees increased steadily in cold resistance from the time of leaf fall to midwinter. Observations on seven groups of seedlings, each the open-pollinated progeny of a single tree, showed significant differences in the average injury to the seven progenies on different dates, and also that the average injury for all tests was significantly less in certain progenies. Freezing tests of seedlings treated differently with respect to fertilizer gave indications that heavy nitrogen treatment was harmful and that some benefit resulted from phosphorus.

**Response of bulbous iris to preplanting treatments, D. V. LUMSDEN. (U. S. D. A.).** (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), p. 414).—None of several preplanting treatments, tried out chiefly on the Wedgewood and Emperor

varieties, caused well-developed buds to fail to open when forced later in the greenhouse. The different storage treatments did cause decided variations in the number of days to reach flowering and exerted certain other growth effects of lesser significance.

**Problems in forcing Easter lilies, K. Post.** (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 415-418).—Phosphate applied to the soil in which bulbs were potted delayed flowering but did not reduce the stem length. The removal of scales or parts of scales reduced the number of flowers per bulb and the height of the plants. A temperature of 50° F. during the early period of growth delayed flowering but tended to increase the number of flowers per plant. The time required to reach flowering was reduced as the temperature was increased to 70°, but there were fewer buds per plant. Supplemental light hastened flowering when the temperature was below 65°, but reduced the number of buds. Supplemental light had no effect on the time of flowering at 65° or more.

**Further studies on factors affecting the forcing performance of Easter lily bulbs, P. BRIERLEY and A. H. CURTIS.** (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), p. 432).—Creole lily bulbs dug at six dates from June 16 to August 16 and stored at 50° F. came into bloom in the greenhouse from October 23 to January 28, according to date of digging. The combination of early harvest and 50° storage brought domestic bulbs into bloom in time to compete with imported bulbs stored from the preceding season. Bulb maturity at harvest was the limiting factor, as shown by the fact that some of the bulbs dug in June were not sufficiently mature to respond to storage treatment. Bulbs affected with mosaic disease were slower to emerge and to bloom and bore inferior flowers.

**Effect of aeration on growth of hybrid tea roses, A. W. BOICOURT and R. C. ALLEN.** (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 423-425).—Signora roses budded on *Rosa multiflora* stocks and grown in (1) clay soil without aeration, (2) clay soil with forced aeration, (3) clay-peat mixture without aeration, and (4) clay-peat mixture with aeration made 37.3, 68.4, 81.2, and 155.8 in. of average linear growth per plant, respectively, in the period June 18 to September 18, 1940. The mean O<sub>2</sub> contents of the media were 18.8, 20.3, 19.3, and 20.2 percent, and the mean CO<sub>2</sub> contents were 1.5, 0.3, 1.9, and 0.6 percent, respectively. Although the O<sub>2</sub> differences were small, it is conceded possible that the rose plants may have responded to the small increments. Furthermore, there may have been regions of lower O<sub>2</sub> content than shown by the tests. Other factors besides O<sub>2</sub> content may have contributed to the favorable results in the aerated soil-peat. Determinations of NO<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>, and K<sub>2</sub>O showed no detectable differences attributable to soil treatment.

**Some factors causing fading in color of rose blooms, J. C. RATSEK.** (Tex. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 419-422).—Observations on the flowers of Talisman rose plants pruned to various degrees showed a progressive decrease in color as the intensity of the pruning increased. In defoliation experiments, stems with leaves produced more pigment in their blooms than did defoliated stems. Sugar solutions, introduced through a leaf petiole, appeared to increase pigment formation in the nondefoliated but not in the defoliated stems. The color was lighter when there were more blooms per stem, apparently the result of competition for available carbohydrates. Covering buds with brown or glassine paper reduced the formation of pigments, suggesting that sunlight may be necessary for the full development of the red pigment. Defoliation experiments with other varieties confirmed the results with Talisman. It is suggested that the summer fading of roses may

be due to the effect of higher temperatures in increasing wood growth and thus decreasing the carbohydrates needed in pigment formation.

**Ornamental trees and shrubs for New Mexico, J. V. ENZIE** (*New Mexico Sta. Bul.* 284 (1941), pp. 48, figs. 31).—This bulletin contains general information as to the adaptability and characteristics of various ornamentals useful for planting in New Mexico. An article by F. F. Whitley is appended which divides the State into zones suitable for various species.

**The winter hardiness of some ornamental woody plants of New York State, J. F. CORNMAN** ([*New York*] *Cornell Sta. Bul.* 772 (1941), pp. 32, figs. 6).—Composed largely of specific information on the winter hardiness of various ornamental plants, arranged alphabetically by their botanical names, this bulletin presents information as to the nature and causes of winter injury, factors involved in the development of resistance or susceptibility, and methods of protecting plants from low-temperature injury. A hardiness map, dividing the State into six zones, is presented, together with information as to the typical plant response and climate in each of these zones.

**Growth of pin oak following transplanting and pruning, A. M. S. PRIDHAM**. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), p. 440).—Girth measurements on pin oaks of approximately 4-in. caliper when transplanted in the fall of 1937 revealed greatly reduced growth, extending at least into the third season, as compared with unmoved trees. Since neither root pruning nor top pruning in April 1940 had any significant effect on growth of pin oaks that season, the author suggests that other factors in transplanting, such as season, the soil preparation, and care in handling, may have been involved.

**Response of red oak to fertilization with ammonium sulfate, A. M. S. PRIDHAM**. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), p. 439).—Red oaks planted as street trees were fertilized from 1936 through 1940 with  $\text{NH}_4\text{SO}_4$  at the rate of 10 oz. for each inch of trunk diameter. The fertilizer was broadcast or placed in holes 10–12 in. deep. For comparison, a complete fertilizer 6-8-4 was used at the same rate based on N content. The major response was in autumn color. As compared with 84 percent of the control trees taking on autumnal color October 15 to November 1, only 28 percent turned color where the  $\text{NH}_4\text{SO}_4$  was placed in holes. With complete fertilizer none of the trees showed autumnal color by November 1.

## FORESTRY

[**Forestry studies by the Alabama Station**] (*Alabama Sta. Rpt.* 1940, pp. 7–8, 30–32).—The following studies are briefly discussed: Present and potential production of farm woodland areas in Marion County, by B. T. Lanham, Jr.; the quantity and quality factors as affected by stand in second-growth pines, by L. M. Ware and J. E. Bryan, Jr.; and selectivity studies on slash pine and loblolly pine underplanted in an existing hardwood stand, by W. R. Boggess and Bryan.

**Methods of forecasting timber growth in irregular stands, W. G. WAHLENBERG** (*U. S. Dept. Agr., Tech. Bul.* 796 (1941), pp. 56, pl. 1, figs. 7).—There is included a discussion of numerous specific questions connected with the problem of predicting timber growth of irregular stands over relatively short periods of time. Some of the pitfalls in using growth percentage are pointed out, and the several variations of the stand-table-projection method are discussed. The principal steps of forecasting by this method are presented in detail. The more common fallacies involved in forecasting growth are outlined, and a method of converting a stand table using one diameter-class interval to the equivalent

table using another class interval is illustrated. Assumptions, hypotheses, and other possible sources of errors of unknown magnitudes, e. g., the failure to make correct allowance for mortality or for acceleration or deceleration of growth, are discussed. The recurring-inventory method of determining growth is reviewed because it promises to become the principal means of control in the more intensive management of irregular forests.

**A preliminary study of growth in the beech, *Fagus grandifolia*, by the dendrographic method, R. C. FRIESNER** (*Butler Univ. Bot. Studies*, 5 (1941), *Papers 1-8*, pp. 85-94, fig. 1).—Records taken on three trees with the aid of dendrometers and a dendrograph showed the first changes in growth at the time the leaves attained full size, about the middle of May in 1940. Radial increases rose steadily to maximal rates in the week ended June 17 and then declined steadily to the zero point about July 15. Radial losses resulting from excess transpiration occurred from July 15 to August 12. The dendrometer showed slightly longer radii at the time of leaf fall than on July 15. The influence of several factors, rainfall, temperature, and light, on diametral growth are discussed and are believed to constitute a complex governing growth. Daily curves showed maximum diameters about 6 a. m. and minimum from 4 to 6 p. m.

**Forest replacement rates in the Colorado Headwaters area, R. L. IVLS** (*Bul. Torrey Bot. Club*, 68 (1941), No. 6, pp. 407-408).—Observations on an area located largely in Grand County, Colo., with an elevation of 8,000 to 11,000 ft. and burned over in 1862 and 1863, indicated the following replacement rates in terms of years since the original fire: Maximum brush growth 25, maximum aspen growth 40, aspen largely eliminated 65, and estimated complete elimination of burned effects 300 yr.

**Longevity of black cherry in Pennsylvania, A. F. HOUGH.** (U. S. D. A.). (*Forest Leaves*, 30 (1940), No. 2, p. 16, fig. 1).

**Strength properties of Chinese elm grown in Michigan, A. J. PANSIN** (*Michigan Sta. Quart. Bul.*, 24 (1941), No. 2, pp. 115-117).—Chinese elm wood (*Ulmus pumila*) has a specific gravity of about 0.5, based on oven-dry weight and volume. The sapwood is light yellow, while the heartwood ranges from brown to dark brown, with a reddish tinge. The wood when planed has a good figure caused by the alternate bands of the open-textured, lighter-colored springwood and the close-textured, darker summerwood.

Testing machine data indicate that the fast-grown wood of Chinese elm is inferior in modulus of elasticity to the wood of average strength of the three American species of elm. It is comparable to American elm (*U. americana*) in modulus of rupture and in shear parallel to the grain, but is inferior in this respect to slippery elm (*U. fulva*) and to rock elm (*U. thomasi*). In compression parallel to the grain, the samples of Chinese elm tested were superior to American elm, comparable to slippery elm, and inferior only to rock elm. In hardness, both on end and side grain, Chinese elm was excelled only by the rock elm. On the basis of strength, fast-grown Chinese elm may be considered equal to American and slippery elms except in static bending, in which it has a considerably lower modulus of elasticity.

**The identification of coniferous woods by their microscopic structure, E. W. J. PHILLIPS** (*Jour. Linn. Soc. London, Bot.*, 52 (1941), No. 348, pp. 259-320, pls. 3, figs. 5).

**Fire Control Notes, [January 1942]** (U. S. Dept. Agr., Forest Serv., *Fire Control Notes*, 6 (1942), No. 1, pp. II+44, figs. 13).—In the usual form (E. S. R., 86, p. 200), information is presented on fire prevention, fire-fighting plans and equipment, technics, etc.

## DISEASES OF PLANTS

**The Plant Disease Reporter**, [December 1 and 15, 1941] (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 25 (1941), Nos. 22, pp. 539-555; 23, pp. 555-591, figs. 3).—In addition to the host-parasite check-list revision, by F. Weiss (Nos. 22, *Piper* to *Populus*, and 23, *Populus* continued to *Prosopis*), the following items are noted:

No. 22.—An abnormality of *Abies balsamea* due to *Sclerotinia kerneri* or a closely related fungus, by E. K. Cash; a systemic arsenic toxicity of peach and apricot on old apple land, by E. C. Blodgett; nut diseases (Persian walnut and filbert) in the Pacific Northwest in 1941, by P. W. Miller; some observations on cereal diseases in Virginia in 1941, by S. B. Fenne; cereal rusts in the Great Plains region (Texas, Oklahoma, and Kansas); and a brief note on *Cercospora* leaf spot on *chrysanthemums* in Alabama.

No. 23.—Collections of fungi, bacteria, and nematodes of grasses (an annotated list), by C. L. Lefebvre and H. W. Johnson; peanut diseases in certain Texas counties in 1941, with notes on occurrence of peanut rust, by G. Ken-Knight; and brief notes on an isolated case of black shank on tobacco in Kentucky and black canker (*Phybaslospora niyabeana*) of willow in West Virginia.

**Plant science section** (*Jour. Colo.-Wyo. Acad. Sci.*, 2 (1940), No. 6, pp. 35-38; 3 (1941), No. 1, pp. 33-39).—The following abstracts of papers are of interest to plant pathology:

Vol. 2, No. 6.—Pathogenicity and Sexual Phenomena Exhibited by *Phytophthora capsici*, by W. A. Kreutzer, L. W. Durrell, and E. W. Bodine (p. 35). The Pigment of *Phoma terrestris*, by W. A. Kreutzer (p. 36), and The Effects of Growth Inhibiting Substances on *Fusaria* From Carnations, by J. L. Forsberg (p. 36) (all Colo. State Col.); and Some Practical Measures in the Control of Ring Rot of Potatoes, by G. H. Starr (p. 36) (Univ. Wyo.).

Vol. 3, No. 1.—The Relation Between the Pathogenicities of Three Root-Rotting Organisms of Wheat, by W. D. Thomas, Jr. (p. 36) (Colo. State Col.); *Verticillium* Wilt of Sugar Beet, by J. O. Gaskill and W. A. Kreutzer (pp. 36-37) (U. S. D. A. and Colo. State Col.); and The Effect of Soil Temperature on *Fusarium* Wilt of Carnations, by J. L. Forsberg (p. 37) (Colo. State Col.).

[Plant disease work by the Alabama Station] (*Alabama Sta. Rpt.* 1940, pp. 18, 20-21).—Brief reports are included on cotton rust due to K deficiency; and on *Sclerotium rolfsii*, *S. trifoliorum*, *Colletotrichum trifolii*, *Stagonospora meliloti*, and *Botrytis* sp. as factors in the elimination of white clover from Alabama pastures during summer.

[Plant disease studies by the Colorado Station] (*Colorado Sta. Rpt.* 1941, pp. 11-12, 18-19, 30-31, 31-32, 37).—Brief reports of progress are included on bacterial winterkilling in alfalfa, with particular reference to inheritance of resistance and hardiness; ring rot of potato, diagnosis, the soft rots following it, and control; chlorosis of stone fruits and its control; resistance of carnations to root rot; peach mosaic; a new *Macrosporium* rot of potato; and histology of winter injury in raspberry canes.

**Enfermedades de las plantas cultivadas en la Provincia de Santa Fe, II** [Diseases of cultivated plants in the Province of Santa Fe, Argentina, II], E. SCHIEL (*Inst. Eapt. Invest. y Fomento Agr. Ganad. [Santa Fe, Argentina], Pub. Tec.* 21 (1940), pp. 23).—A continuation of the annotated list previously noted (E. S. R., 84, p. 200).

**Enfermedades y plagas principales de la agricultura Uruguay** [The principal diseases and pests of Uruguayan agriculture] (*Uruguay Min. Ganad.*

*y Agr., [Pam.] 55 (1941), pp. [1]+19*).—This is an annotated list of the most important diseases due to fungi, bacteria, and viruses, and the principal insect pests of economic crops, giving hosts, distribution, etc.

**Itogi nauchno-issledovatel'skikh rabot vsesoiuznogo instituta zashchity rastenii za 1939 g.** (Summary of the scientific research work of the Institute of Plant Protection for the year 1939) (*Moskva: Vsesoiuzn. Akad. Sel'sk. Khoz. Nauk Lenina, Inst. Zashch. Rast., 1940, pp. 184, figs. 19*).—The following are of interest to phytopathology: *Kratkie itogi rabot po fitopatologicheskomu obosnovaniyu selektsii i ofsenki sortov na ustoiichivost' k zabolevaniyam v razreze gruppovogo immuniteta* (Brief Results of the Work Upon the Phytopathologic Basis of Selection and Estimation of Sorts Upon Resistance to Diseases in the Interpretation of Group Immunity), by T. I. Fedotova (pp. 52-58); *Itogi rabot po rzhavchine khlebynykh zlakov* (Results of the Work Upon Cereal Rust), by K. (C.) M. Stepanov (pp. 58-67); *Prichiny vspyshek sil'nogo pazvitiia sklerotiniia i snezhnoi pleseni na ozimnykh posevakh i uvadaniia sel'skokhoziaistvennykh kul'tur* (The Causes of Outbreaks of Severe Development of *Sclerotinia* and *Fusarium nivale* on Winter Sowings and Withering of Agricultural Crops), by S. M. Tupenevich (Toopenevitch) (pp. 67-71); *Itogi rabot po obosnovaniyu termicheskogo i khimicheskogo metodov bor'by s pyl'noi i mokroi golovnei pshenitsy* (Results of the Works for the Basing of Thermic and Chemical Control Measures Against Wheat Bunt (*Tilletia tritici*) and Loose Smut (*Ustilago tritici*) of Wheat), by S. T. Buben'sov (Boobentzov) (pp. 71-74); *Razrabotka mer bor'by s virusnymi bolezniami kartofel'ia i tomatov* (On the Control Measures Against Potato and Tomato Virus Diseases), by M. S. Dunin (Doonin) (pp. 74-80); *Vozbuditeli bakteriozov pshenitsy, iachmenia, i kartofel'ia i metody ikh obnaruzheniia* (The Causal Organisms of Wheat, Barley, and Potato Bacterioses and Methods for Their Detection), by D. E. Belenki (Belenki) (pp. 81-85); *Kratkie itogi raboty laboratorii fitosistematiki VIZR* (Brief Results of the Work of the Phytosystematic Laboratory of the Institute for Plant Protection), by N. A. Naumov (Naomov) (pp. 85-87); *Itogi issledovaniia po obosnovaniyu i ispytaniyu opytnykh variantov sistemy meroprifitiia v sadakh Krasnodarskogo kraia* (Results of Investigations by the Basing and Testing of Experimental Modifications of the Control Method System in the Gardens of the Krasnodar Region), by V. I. A. Parfent'ev (V. J. Parfentiev) (pp. 112-120); *Rezultaty primeneniia gribynykh, bakterial'nykh i virusnykh vozbuditelei boleznei hasekomykh v bor'be s vreditel'ami sel'skogo khoziaistva* (Results of the Utilization of Fungus, Bacterial and Virus Diseases as a Control Measure Against Agricultural Pests), by V. P. Pospelov (pp. 125-129); *Rezultaty rabot po bio i fiziko-khimicheskomu obosnovaniyu zeffektivnosti i konstruirovaniiu fungitsidov dlia bor'by s rzhavchinoi, pyl'noi i tvrdoi golovnei pshenitsy* (Results Upon the Bio- and Physiochemical Basing of the Effectivity and Constructivity of Fungicides for the Control of Rust, Wheat Bunt, and Loose Smut of Wheat), by I. M. Poliakov (pp. 145-150); *Issuchenie vliianiia primesei, vstrochafushchikhsia v preparate "AB," na ego toksichnost'* (The Study of the Influence of Admixtures, Encountered in the Preparation "AB," on Its Toxic Action), by M. S. and I. K. Kholodniuk (I. C. Holodniok) (pp. 150-152); and *Itogi nauchno-issledovatel'skikh rabot VIZR po mekhanizatsii zashchity rastenii* (The Results of Scientific Research Work of the Institute for Plant Protection Concerning the Mechanization of Plant Protection), by I. P. Iafsenko (Jatzenko) (pp. 153-181).

**Soil treatments for the control of diseases in the greenhouse and the seedbed**, A. G. NEWHALL, C. CHUPP, and C. E. F. GUTERMAN (*N. Y. State Col. Agr., Cornell Ext. Bul. 217, rev. (1940), pp. 58, figs. 31*).

**New and improved methods for study of fungicides**, J. M. HAMILTON and G. L. MACK (*Farm Res. [New York State Sta.]*, 8 (1942), No. 1, pp. 10, 13).—A brief summary of recently developed laboratory and greenhouse procedures for evaluating the efficiency of spray materials before they are recommended to the public.

**Spray injury studies: Progress report II.**—The effects of time and temperature on the production of hydrogen sulphide during atmospheric decomposition of lime sulphur, W. E. BERRY (*Univ. Bristol, Agr. and Hort. Res. Sta., Long Ashton, Ann. Rpt.*, 1939, pp. 52–56, fig. 1).—A continuation of previous work (E. S. R., 82, p. 784).

**Radioactive copper and the mechanism of oligodynamic action**, D. MAZZA and L. J. MULLINS. (Univ. Calif., Univ. Mo., et al.). (*Nature [London]*, 147 (1941), No. 3734, p. 642).—Using leaves of *Elaeagnus canadensis*, it is concluded that Cu in extreme dilutions exerts its physiological effects by virtue of the power of protoplasm to bind ions against a concentration gradient, so that the concentrations actually present are relatively high. These concentrations later decrease in the cell, and the physiological effect of the heavy metal ion disappears concomitant with this decrease in concentration.

**The effect of certain chemicals, some of which produce chromosome doubling, on plant tumors**, N. A. BROWN (*Phytopathology*, 32 (1942), No. 1, pp. 25–45, figs. 2).—The chromosome-doubling agents acenaphthene,  $\alpha$ -methyl-naphthalene,  $\alpha$ -nitronaphthalene, 3,5-dibromopyridine, and apiole failed to act on *Bacterium* (= *Phytomonas*) *tumefaciens* tumors in the same way as colchicine (E. S. R., 81, p. 53). The tumor cells seemed to have their own specific response to a chemical according to plant species and, with a few exceptions, according to age of tumor. No excessive chromosome doubling in nuclei of young tumors thus treated took place as it did with colchicine treatment. There was no stimulation of tumor growth by acenaphthene, except where tumors were brushed with it in chlorinated-naphthalene solution and temporarily in seedling marigolds watered with a saturated aqueous solution. Acenaphthene dissolved in dioxan did not produce the noticeable stimulation of tumor development so characteristic of colchicine before inhibition and death. Three percent acenaphthene in dioxan failed to kill marigold tumors (young or old) or young Paris daisy tumors, but killed the latter when 36 or more days old. Any growth inhibition in marigold tumors by acenaphthene dissolved in dioxan was usually overcome. Dwarfing occurred when apiole was brushed on tumors, but no darkening or death. Full-strength or 50 percent emulsion of  $\alpha$ -methyl-naphthalene brushed on young marigold and Paris daisy tumors inhibited further growth and killed old but growing tumors on both hosts. With  $\alpha$ -methyl-naphthalene brushed on stem tumors of the related *Bryophyllum pinnatum* and *Kalanchoe daigremontiana*, in a month there was no effect on the first, whereas *Kalanchoe* tumors were dead in 2 weeks.  $\alpha$ -Nitronaphthalene and 3,5-dibromopyridine in saturated aqueous solutions and in lanolin paste brushed on young and old Paris daisy and marigold tumors gave negative results. Heptyl aldehyde and methyl salicylate, not known to be polyploidizing agents but used by animal pathologists in the control of mouse tumors, were also applied to bacterial plant tumors. Brushing normal heptyl aldehyde full strength on 12 14-day-old marigold tumors killed them in 24 hr., whereas 18-day-old daisy tumors became slightly shrunk. In 3 weeks only half of the 18-day-old tumors were dead. A 20 percent emulsion of *n*-heptyl aldehyde killed 20 25-day-old marigold tumors in 3 days, but 8-day-old marigold tumors were not affected. A 10 percent emulsion of this chemical killed 10 46-day-old daisy tumors. Full strength  $\alpha$ -methyl salicylate killed 30- to 44-day-old but not 12- to 15-day-old marigold tumors. Paris daisy tumors 16–26 days

old were killed with  $\alpha$ -methyl salicylate, and tumors 7 days old when brushed were inhibited.

**Molds found in Indianapolis markets**, P. LENIZ (*Buller Univ. Bot. Studies*, 5 (1941), *Papers 1-8*, pp. 58-66).—From September 15 to December 15, 1939, 21 mold genera were isolated from fruits and vegetables in Indianapolis markets. *Penicillium*, *Rhizopus*, *Aspergillus*, and *Alternaria* predominated, followed by *Oospora*, *Fusarium*, *Monilia*, *Monosporium*, and *Isaria*. Plants which were host to 4 or more genera were banana, cabbage, carrot, eggplant, onion, potato, and tomato. *Alternaria* and *Fusarium* grew predominantly on hosts growing in or near the soil, *Aspergillus* and *Monilia* were more common on ordinary orchard fruits, whereas *Penicillium* was the only genus found on citrus fruits.

**Descriptions of tropical rusts, IV**, G. B. CUMMINS. (*Ind. Expt. Sta.*). (*Bul. Torrey Bot. Club*, 68 (1941), No. 7, pp. 467-472, figs. 4).—This installment (*E. S. R.*, 84, p. 773) contributes seven new species and two new combinations in rust taxonomy.

**Om Nomenklatur for Plantevira samt nogle Synonymer for Kartoffelvira og Kartoffelvirosor** [The nomenclature of plant viruses, together with a list of synonyms of potato viruses and viroses], H. P. HANSEN (*Tidsskr. Plantevir.* 46 (1941), No. 2, pp. 363-372; *Eng. abs.*, pp. 369-372).—The various nomenclatorial systems are discussed, and the synonyms for the European potato viruses are listed.

**Crown gall production by bacteria-free tumor tissues**, P. R. WHITE and A. C. BRAUN (*Science*, 94 (1941), No. 2436, pp. 239-241).—The results of studies summarized in this preliminary report, in which the techniques for in vitro culture of excised plant tissues were used, appear to furnish almost unquestionable evidence that crown gall tissues may multiply rapidly without continued stimulation from *Phytoplasma tumefaciens* once their capacity for autonomous growth has become established. The data apparently indicate that the tumor-inducing capacity was retained by bacteria-free tissues through at least 10 successive passages in vitro. It seems clear that the affected tissues underwent a drastic change, indicated by their capacity to produce galls, a quality not found in normal tissue, and by their behavior in vitro, where their growth habits differed markedly from those of normal tissues under identical conditions. It is believed that this change is brought about originally by some stimulus from the crown gall organism, but that its maintenance does not depend on the continued presence of these bacteria.

**The relation between Polyporus abietinus (Dicks. ex Fr.) Fr. and Irpex fuscoviolaceus (Ehrenb. ex Fr.) Fr.**, R. RAESTAD (*Nytt Mag. Naturv.*, 81 (1941), pp. 207-231, figs. 5).—This study of the taxonomic history, occurrence, morphology, appearance in culture, wood decay induced, and sexuality of these fungi is believed to demonstrate that the two European forms, connected by the American intermediate types, are members of a complex of nearly related forms which must be considered as one species, for which *P. abietinus* is the preferred name. The diagnosis of this species must include all the American forms, whereas the subspecies are restricted to the comparatively homogenous forms occurring in Europe.

**Technique for artificially feeding Scolytus multistriatus and Saperda tridentata spores of Ceratostomella ulmi and other substances**, W. D. BUCHANAN and C. MAX. (U. S. D. A.). (*Phytopathology*, 32 (1942), No. 1, pp. 95-97, fig. 1).—Adults of *Scolytus multistriatus* attached by their feet with cellulose glue to the ends of match sticks freely fed upon aqueous suspensions of *C. ulmi*, Neoprontosil, ground elm bark, and arsenic. The Neoprontosil solutions were fed directly into the mouths of the beetles, using a micromanipulator

and micropipette. The other solutions were ingested from the ends of small tubes. Ground bark similar to that ingested was found in the digestive tracts of several dissected beetles. This method renders it possible to remove and culture pellets of feces to determine the viability of *O. ulmi* after passage through the digestive tract. The same technic was successfully used with *S. sulcatus* and *Saperda tridentata*.

**Factors influencing variety yield differences in 1941.** T. E. STOA (*North Dakota Sta. Bimo. Bul.*, 4 (1941), No. 2, pp. 6-10).—Leaf rust of wheat, crown rust of oats, and flax rust were abundant in 1941 and varieties lacking resistance to these diseases were at a distinct disadvantage. This was especially true in eastern North Dakota and in other areas where these rusts were unusually severe. Some stem rust was present, but no serious injury on either wheat or oats was evident. Comparisons with other years are briefly noted, and the results of yield trials with the commonly grown varieties of wheat, oats, and flax are discussed and tabulated.

**Susceptibility of Lee × Victoria oat selections to loose smut.** G. M. REED and T. R. STANTON. (U. S. D. A. et al.). (*Phytopathology*, 32 (1942), No. 1, pp. 100-102).—A specimen of *Ustilago avenae* collected in Oklahoma (1934) was sent to the Brooklyn Botanic Garden where it was found to produce smut on Victoria oats and on certain hybrid strains derived from it. The Victoria and Lee varieties were infected 43.8 and 92.6 percent, respectively, whereas 22 selections from the Lee × Victoria cross exhibited an infection range of 6.6-68 percent. This race of the loose smut fungus is of special interest because of its pathogenicity for Victoria oats, a variety hitherto resistant to all known races of both oats smuts. It is designated race A-30.

**En enkel snabbmetod för prövning av betningsmedlens verkan mot havreflygsot, Ustilago avenae (Pers.) Jensen [A simple rapid method of testing fungicides against oats loose smut, U. avenae].** A. ZADE (*Nord. Jordbruksforsk.*, 1940, No. 7-8, pp. 244-255; *Ger. abs.*, pp. 252-255).

**Scab of wheat and barley.** J. J. CHRISTENSEN and R. C. ROSE (*Minn. Univ. Agr. Ext. Folder* 97 (1941), pp. [6], figs. 12).

**An epiphytotic of wheat septoriosiis [in Argentina].** J. B. MARCHIONATTO (*Internatl. Bul. Plant Protect. [Roma]*, 15 (1941), No. 6, pp. 113M-114M).—*Septoria tritici* and *S. nodorum* were concerned, the latter causing the most damage.

**Soil conditions and the take-all disease of wheat.—VI, The effect of plant nutrition upon disease resistance.** S. D. GARRETT (*Ann. Appl. Biol.*, 28 (1941), No. 1, pp. 14-18).—In further studies (W. S. R., 85, p. 208), Red Marvel spring wheat was grown in sand culture with full nutrients and with deficiencies in N, P, and K and in all three together. After a month's growth the plants were inoculated with *Ophiobolus graminis*. Satisfactory root infection occurred in all cases but was lightest in the N-deficient plants, whereas the K-deficient plants had a rather more intense root infection than any of the other series. Percentage infection of the stem bases was lowest in the full nutrient and N-deficient plants, and highest under deficiency of all three nutrients. In the uninoculated controls, a significant depression in grain yield was produced only by P deficiency, but in the inoculated plants deficiency in any one of the three nutrients significantly reduced the grain yields. Infection significantly reduced yields in every series except that receiving full nutrients. The percentage reduction was greatest in the P-deficient plants.

**Effect of certain environmental conditions on the prevalence of Ophiobolus graminis in the soil.** H. FELLOWS. (U. S. D. A. coop. Kans. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 63 (1941), No. 12, pp. 715-726, figs. 3).—In pure culture

the fungus causing take-all of wheat was not killed by Kansas winter temperatures, nor was it affected by repeated abrupt alternations of growing and subfreezing temperatures. The thermal death point of both microhyphae and macrohyphae was about 50° C., and in spontaneously infested soil the fungus withstood 71°. Summer drought or high temperatures reduced soil infestation only slightly, nor was the abundance of the fungus in soils reduced by repeated alternations from growing to subfreezing temperatures. The abundance of the parasite in infested soil as measured by disease in subsequently grown wheat was reduced in varying degrees by different combinations of moisture, temperature, and compactness of the soil during a storage period. However, it remained viable as long as 777 days in moist or dry soil stored in a warm greenhouse. In general, soil stored in a cool cave tended to retain the fungus longer than warm soil, and it was reduced most in a warm, loose, moist soil and least in a cool, compact, moist soil.

**Wind dissemination of angular leaf spot of cotton, J. G. BROWN.** (Univ. Ariz.). (*Phytopathology*, 32 (1942), No. 1, pp. 81-90, figs. 3).—Commercial cottonfields in Arizona so located and planted as to fulfill experimental requirements were studied in relation to wind dissemination of *Phylomonas malvacearum*, the cause of angular leaf spot (black arm). In an area with easterly summer winds prevailing, virgin soil was planted with ILSO-delinted and Ceresundusted seed, and similar tracts were sown with untreated seed from the same lot—one field on the east and one on the west of the area. Control fields some miles distant were planted with seed from a common lot and with identical treatment. All were irrigated from individual wells, thus insuring against spread of inoculum from one field to another in the irrigation water. Cotton growing in the area of mixed planting (fields from treated and untreated seed) were wounded on their eastern sides by an August hailstorm. One week later they were subjected to a violent duststorm moving towards the west. Subsequently, black arm practically ruined the crop in the affected area. Evidence is presented to prove that inoculum carried by wind-blown dust originating in the fields grown from untreated seed caused the infection and resulting losses. No black arm appeared in the second area in fields used as controls.

**Aecidium gossypii, the aecial stage of Puccinia boutelouae, J. T. PEFSELY.** (Minn. Expt. Sta. coop. U. S. D. A.). (*Phytopathology*, 32 (1942), No. 1, pp. 97-99).—Greenhouse inoculations established the connection of *A. gossypii* on cotton with a *Puccinia* sp. on *Bouteloua* spp. tentatively identified as *P. boutelouae*.

**Antecedentes sobre la "roya" del algodón en la Republica Argentina [Comments on cotton rust in Argentina], M. A. DI FONZO** (*Argentina Min. Agr., Junta Nac. Algodón, Bol. Mens. No. 78* (1941), pp. 419-420, fig. 1).—This review considers some aspects of this generally little known rust of cotton (*Cerotelium desmii*) in Argentina, referring to the history and nomenclature of the fungus and to the symptoms, transmission, and importance of the disease.

**La stenosis: Un achicamiento y arrugamiento del algodón [Stenosis: A stunting and crinkling of the cotton plant], R. OBREGÓN BOTERO** (*Bogotá, Colombia: Min. Econ. Nac., 1940, pp. 16, figs. 6*).—The symptoms of this disease, involving reductions in size of plant and rolling of leaves, are described in detail and compared with other deformation troubles (brachymia, tomosis, hybosis, acromania, cyrtosis, and mosaic). Theories as to the cause are discussed, the author inclining toward a virus etiology. The questions of resistance and other means of control are considered, with recommendations.

**Flax wilt (*Fusarium lini*) in New England**, G. T. S. BAYLIS (*New Zeal. Jour. Sci. and Technol.*, 22 (1940), No. 3A, pp. 157A-162A, figs. 2).—A general discussion of flax wilt, only recently recognized in New Zealand, and its control.

**Studies on *Uromyces lespedezae-procumbentis* in Japan**, N. HIRATSUKA (*Tottori Nōgaku-Kwaihō* (Trans. Tottori Soc. Agr. Sci.), 7 (1940), No. 1-4, pp. 63-79; *Jap. abs.*, p. 79).—The author reports 21 species of *Lespedeza* as hosts of this rust in Japan. As a result of inoculation tests on different hosts, he establishes 3 specialized form species of the collective species, viz. *U. macrolespedezae*, *U. lespedezae-cuneatae*, and *U. lespedezae-pilosae*. The collective species *U. lespedezae-procumbentis* is very widely distributed in Japanese territories, extending from Hokkaido on the north to the Rinkiu Islands and Taiwan (Formosa) on the south.

**Eye-spot of Napier grass in Hawaii, caused by *Helminthosporium sacchari***, G. K. PARRIS. (Hawaii Expt. Sta.). (*Phytopathology*, 32 (1942), No. 1, pp. 46-63, figs. 6).—This disease of *Pennisetum purpureum* in Hawaii, first appearing in October 1939, has caused severe losses, entire plantings being rendered useless for fodder and many fields replanted with other grasses. The causal agent is *H. sacchari*, for which *H. ocellum* is believed to be a synonym. Comparing the physiology of eight isolates of the fungus from Napier and one isolate from sugarcane, the former has an optimum of 21°-28° C., whereas that for the cane fungus has been variously reported as 20°-20°, 23.5°, and 30°. On certain substrates, at uniform temperature, there was little or no difference in appearance of the isolates from Napier and from cane; on others the cane fungus resembled certain Napier isolates but was distinct from other Napier isolates. Within the isolates from Napier, great variation in type of growth occurred on certain media. The fungus isolated from Napier produced larger spores at 28° than at 21°, but when isolated from cane the spores were larger at 21° than at 28°. These differences are not believed to be due to different species of *Helminthosporium* but to different strains of the single species *H. sacchari*. The Napier fungus was isolated, inoculated into healthy plants, the disease reproduced, and the fungus recovered in pure culture. Inoculated into sugarcane, Napier isolates have little effect, and the same is true of *H. sacchari* isolated from cane and inoculated into Napier. Merker grass, a variety of Napier, and certain reciprocal Napier×Merker crosses proved highly resistant. The local disease is controlled by substitution of this resistant material.

**Potato diseases and their control**, T. P. DYKSTRA (*U. S. Dept. Agr., Farmers' Bul.* 1881 (1941), pp. II+65, figs. 50).—This describes the characteristics of the diseases and discusses the methods of control.

**Potato disease control by breeding resistant varieties**, F. J. STEVENSON. (U. S. D. A.). (*Iowa State Hort. Soc. [Rpt.]*, 74 (1939), pp. 221-235, fig. 1).—A summary of the national potato breeding program and discussion of potato breeding methods and equipment and of resistance to late blight and common scab.

**Spraying and dusting potatoes**, R. BONDE and W. C. LIBBY (*Maine Agr. Col. Ext. Bul.* 290 (1940), pp. 14, figs. 7).

**Three years of potato spraying in southeastern Wisconsin**, O. C. WHIFFLE and T. C. ALLEN. (Wis. Expt. Sta.). (*Amer. Potato Jour.*, 18 (1941), No. 9, pp. 254-261).—In these 3-yr. tests on Irish Cobbler potatoes, varying the seasonal distribution of CuSO<sub>4</sub> and lime in bordeaux mixture had no advantage over the standard 5-5-50 formula. For commercial growers of this variety in southeastern Wisconsin this formula proved equal to or better than any of the other bordeaux formulas or fixed coppers tested in increasing yields. Certain proprietary compounds tested may, however, be used wisely by small growers or

home gardeners, since they are more convenient to make up and apply. Spraying may be expected to increase yields in relatively dry years when leaf diseases are not a factor, but in cool, wet years this response is less evident unless leaf blights appear early and become destructive.

**Salaman's culture of blight resistant "Aya papa,"** J. G. HAWKES and H. W. HOWARD (*Nature [London]*, 148 (1941), No. 3740, p. 25).—This note is of interest in connection with a paper by Reddick (E. S. R., 83, p. 70) on the distribution of blight-resistant potatoes on the American Continent, and refers to the origin of the resistant potato from Ecuador known as Aya papa.

**Infection of first-year potato seedlings with *Fusarium solani* var. *cumartii*,** J. H. JENSEN and R. W. GOSS. (Nebr. Expt. Sta.). (*Amer. Potato Jour.*, 19 (1941), No. 8, pp. 239-242).—Testing first-year seedlings for *Fusarium* wilt resistance in the greenhouse proved a rapid and satisfactory method of eliminating susceptibles, overcoming the disadvantage of cost in growing plants from tubers in the greenhouse and reducing the large number of escapes that often occur in the field. Although seedlings of desirable horticultural quality may be lost, the high percentage of infection obtained in all crosses thus far tested would indicate that the chances of securing resistant seedlings after selection has been made for other characters would be slight.

**The effects of mosaic diseases on potatoes,** R. J. SCOTT (*Scot. Jour. Agr.*, 23 (1941), No. 3, pp. 258-264).—Statistics are presented on the effects of four grades of mosaic, viz, negligible mottle, mild mosaic, borderline severe mosaic, and severe mosaic; leaf roll; and the wilding group, the severer forms reducing the yields by as much as 95 percent. The presence of virus induced earlier ripening. Severe mosaic increased on the average by twofold to threefold and leaf roll by fourfold from year to year. Control measures are outlined.

**Studies on soil actinomycetes in relation to potato scab and its control,** G. KENKNIGHT (*Michigan Sta. Tech. Bul.* 178 (1941), pp. 48).—Under the test conditions, none of numerous inorganic and organic chemicals and their combinations as soil treatments gave promise of practical control of potato scab in infested Michigan fields, and Hg compounds generally caused marked increases in scabbing. Evidence is presented that the primary reason for conflicting reports in the literature is that parasitic actinomycetes vary widely in their tolerance to Hg compounds. As one example of this situation, calomel controlled scab in both Long Island and Michigan soils artificially infested with actinomycetes from Long Island, whereas the same treatment caused an increase in scabbing in both soils artificially infested with strains from Michigan. In the latter case, there was an initial reduction in numbers of actinomycetes, but those that could tolerate the mercurials multiplied apparently as a result of reduction in competition from other micro-organisms. Mercury vapor appeared to react with substances in nutrient agar to produce substances toxic to micro-organisms, but when dry or in pure water the spores of the actinomycete most sensitive to Hg compounds were not injured by Hg vapor. Mixture of powdered Zn with Hg compounds appeared to accelerate the vaporization of Hg from its compounds. On the other hand, potassium permanganate, though apparently not affecting the toxicity of Hg compounds in solution, prevented the migration of Hg as vapor. Vapor from yellow oxide of Hg moved readily through 6 in. of sandy soils but not through loam, clay, or muck. However, when 0.1 gm. was mixed with 25 gm. of loam and covered with 6 in. of loam the vapor came through. Mixture of acids with mercurials prevented the evolution of Hg vapor. Field applications of HCl (1,500 lb. per acre) with calomel had no lasting effect on the soil reaction and no effect on the tendency of the mercurial to increase scabbing, whereas S, applied with calomel and given time to oxidize,

reduced the effect of the mercurial on scabbing. Soil treatment with calomel increased the scabbing on roots of beets and eggplants but not of radishes, turnips, or rutabagas. Lime plus calomel was more effective than calomel alone in aggravating scab of various *Actinomyces* hosts. In 3-yr. trials, 21 bacterial isolates, 41 actinomycetes, 7 fungi, and 2 yeasts added to scab-infested soils on various media failed to control scab. Green manures of bluegrass and alfalfa caused significant increases, and other forms of organic matter also tended to aggravate scabbing. Evidence was found that *Solanum melongena*, *S. nigrum*, *Amaranthus retrofractus*, and possibly also several other plants are hosts to phytopathogenic actinomycetes.

**Report on potato virus diseases in 1940**, T. P. DYKSTRA. (U. S. D. A.). (*Amer. Potato Jour.*, 19 (1941), No. 8, pp. 221-230).—This is a review (21 references) of some of the papers on potato virus diseases published in 1940.

**Studier over Kartoffelviroser i Danmark.—II, Fortsatte Sortsundersøgelser** [Studies of the potato viruses of Denmark.—II, Varietal tests], H. P. HANSEN (*Tidsskr. Planavl.*, 46 (1941), No. 2, pp. 355-362; *Eng. abs.*, p. 362).—Continuing this study,<sup>2</sup> apparently healthy plants of 15 potato varieties, 11 of which are immune to wart disease, were examined for spontaneous virus infection.

**Virusnye bolezni i favleniia vyrozhdeniia kartofelia v Uzbekistane** (Virus diseases and degeneration in potato of Uzbek), N. N. BALASHIN (*Dok. Vsesoiuzn. Akad. Sel'sk. Khoz. Nauk Lenina* (Proc. Lenin Acad. Agr. Sci. U. S. S. R.), 8 (1941), pp. 22-27, figs. 3).

**Specific transmission of varieties of potato yellow-dwarf virus by related insects**, L. M. BLACK (*Amer. Potato Jour.*, 19 (1941), No. 8, pp. 231-233).—The New York and New Jersey varieties of the yellow dwarf virus, shown by cross-protection tests to be varieties of the same virus species (*Marmor vastans*), were found to be transmitted specifically by the respective aphids *Aceratagallia sanguinolenta* and *Agallia constricta*. The New Jersey virus form is named *M. vastans agalliae* n. var. The specific relationship between these two virus varieties and their related insect vectors is compared with such highly specialized parasites as the rusts, and the evolutionary possibilities are discussed.

**Wilting of the terminal bud in potato [in Argentina]**, J. B. MARCHIONATTO (*Internatl. Bul. Plant Protect.* [Roma], 15 (1941), No. 9, pp. 161M-162M).—During the 1937-38 and 1938-39 seasons severe damage was reported from the appearance of this disease of then unknown cause. Transmission studies indicated it to be due to a virus found transferable to potato, tomato, tobacco, and pepper, but with difficulty to dahlia. Some of its main properties are given.

**Factors affecting the germination of sugar-beet and other seeds, with special reference to the toxic effects of ammonia**, M. STOUT and B. TOLMAN. (U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 63 (1941), No. 12, pp. 687-713, figs. 6).—Studying the properties of dry- and fleshy-fruit extracts in relation to their action on germinating seeds, sufficient ammonia was found to be released by enzymatic hydrolysis from sugar beet seed-ball extracts and certain other dry-fruit extracts and also from dilute solutions of urea and asparagin to account for their toxic effects. The radicles of germinating seeds, young seedlings, and 2-month-old sugar beet plants were killed in solutions containing 0.3-0.4 mg. of free  $\text{NH}_3$  per cubic centimeter and concentrations as low as 0.1 mg. per cubic centimeter were toxic when maintained.  $\text{NH}_3$  salts such as

<sup>2</sup> *Tidsskr. Planavl.*, 42 (1937), No. 4, pp. 631-681, figs. 7; *Eng. abs.*, pp. 678-681.

(NH)<sub>2</sub>SO<sub>4</sub> proved comparatively nontoxic. The increase in the pH value of extracts or solutions did not fully explain the toxic effects observed. There was a marked differential tolerance of the seeds tested to osmotic pressure, which seemed to account largely for inhibiting the germination of seeds in contact with juices of fleshy fruits. The removal of water-soluble N compounds from pericarpal tissues affords an explanation of the beneficial effects of washing or soaking some seeds prior to germination tests.

**Transmission of chlorotic streak of sugar cane by the leaf hopper *Draculacephala portola*,** E. V. ABBOTT and J. W. INGRAM. (U. S. D. A.). (*Phytopathology*, 32 (1942), No. 1, pp. 99-100).—In an insect-proof greenhouse, five leafhoppers per plant were introduced into insect-proof cages containing infected sugarcane (C. P. 29/320) plants and an equal number of healthy plants grown in steam-sterilized soil in sterilized clay pots from cuttings treated with hot water at 52° C. for 20 min. (a treatment known to eliminate the virus). In other cases the insects were allowed to feed 2-4 weeks on infected plants and then caged with healthy plants alone. Of a total of 490 healthy plants thus exposed to *D. portola*, 25 subsequently developed typical chlorotic streak symptoms. Of these, 20 were from cages containing both diseased and healthy plants, and 5 from cages containing only healthy plants but fed on by insects which previously had fed on diseased plants. Healthy plants caged with infected ones, but without the insects, and other healthy plants growing in the greenhouse along with diseased ones all remained healthy.

**Sweet potato pox** (*New Jersey Stas. Plant Disease Notes*, 19 (1941), No. 3, pp. 9-12).—The disease due to *Actinomyces ipomoea* and its control by application of S to soil are described for the grower.

**Isolation of crystalline tobacco mosaic virus protein using water miscible solvents,** C. G. VINSON. (Univ. Mo.). (*Science*, 94 (1941), No. 2450, p. 551).—An abstract.

**Influence of nitrogen supply on the rate of multiplication of tobacco-mosaic virus,** E. L. SPENCER (*Plant Physiol.*, 16 (1941), No. 4, pp. 663-675, figs. 3).—Turkish tobacco plants grown in sand were supplied with nutrient solutions containing low, medium, or high N supplies, respectively. Assay for virus activity was made on Early Golden Cluster bean, and the virus protein was isolated by air-driven ultracentrifuge. In young plants a difference in virus activity could be detected as early as the fifth day after inoculation, when the juice expressed from low-N plants was only about 35 percent as active as when more N was received, and by the eighth day it was less than 25 percent as active. A threefold difference was recorded in the virus-protein content of the juices under these two treatments. The activity data calculated per plant indicated that by the eighth day after inoculation the juice from the high-N plants contained 12 times more virus than that from the low-N plants. From the fourth to the twelfth day after inoculation the virus-protein content of the juice expressed from the low-N plants increased about 20 times, whereas that of juice from the high-N plants increased over 200 times. Older diseased plants receiving the medium-N solution for longer periods before being given the high-N solution attained greater virus activity as a result of the supplementary N. The data indicate that the larger the plant the more time is required for the increased N supply to become effective. The evidence is interpreted as supporting the view that the increased virus activity associated with an increased N supply is due primarily to an increase in the rate of virus multiplication in the high-N plants and only slightly, if at all, to the partial inactivation of the virus entity in the low-N plants.

**Some properties of tobacco etch viruses,** F. C. BAWDEN and B. KASSANIS (*Ann. Appl. Biol.* 28 (1941), No. 2, pp. 107-118, pl. 1).—The symptoms of severe

and mild etch are described. Both types contain intranuclear and cytoplasmic inclusions. Fewer and larger crystals are formed in the nuclei of plants with mild etch. Seedling plants infected with severe etch developed malformed leaves in which cytoplasmic inclusions crystallized to give rise to birefringent needles. Mild etch protected plants from severe etch, and the two viruses proved to be serologically related. Although not serologically related to potato virus Y or *Hyoscyamus* virus 3, severe etch virus has similar properties in vitro and is transmitted in the same way. The interactions of these three viruses in the plant suggest that they may be related. Plants infected with either of the other viruses are not protected against severe etch, and those infected with potato virus Y are susceptible to *Hyoscyamus* virus 3. Plants with severe etch, however, are protected against the other viruses, and those with *Hyoscyamus* virus 3 are protected against potato virus Y. Severe etch suppresses these two viruses when healthy plants are infected with a mixed inoculum, and supplants them in tissues in which they are already established. Similarly, *Hyoscyamus* virus 3 can suppress and supplant potato virus Y. Possible interpretations are given for these results. Severe etch virus has asymmetrical particles, since concentrated preparations exhibited anisotropy of flow.

**Treatment of tobacco plant bed soil with nitrogenous fertilizers, R. G. HENDERSON.** (Va. Expt. Sta.). (*Agr. News Letter*, 9 (1941), No. 5, pp. 72-78).—Greenhouse experiments with soil infested heavily with black root rot (*Thielaviopsis basicola*) showed that root rot failed to develop on tobacco seedlings grown in this soil after  $\frac{1}{2}$  lb. or more of urea had been applied per square yard and in which the reaction rose from pH 6.9 to more than pH 8.6 for some time from ammonia accumulation due to urea break-down. Weed growth was also suppressed with either urea or calcium cyanamide applied in the fall to tobacco plant beds that were then covered with straw and not seeded until February. Further tests are deemed necessary to determine the manner in which different soil conditions may influence results.

**The relation of boron to the root-nodules of *Vicia faba*, J. DUFRENOY.** (La. State Univ.). (*Growth*, 4 (1940), No. 4, pp. 323-326, figs. 3).—"The symbiotic relations between the nodule bacteria and their host cells are affected by the supply of boron. The behavior of the mitochondria and the effects of the bacteria on the continuance of the host cells are evidence of the importance of boron for the balance between the partners in symbiosis. A deficiency in a mineral nutrient like boron may cause the invading organisms to live as parasites."

**Control of the diseases of vegetable crops, O. D. BURKE and R. S. KIRBY** (*Pa. State Col. Ext. Cir.* 173, rev. (1940), pp. 18, fig. 1).

**Doas molestias de virus do feijoeiro [Two virus diseases of beans (*Phaseolus vulgaris*)], A. S. COSTA and R. FORSTER** (*Biologico*, 7 (1941), No. 7, pp. 177-182, pls. 2).—This paper presents the results of studies of bean mosaic (bean virus 1) and bean yellow mosaic (bean virus 2) as they occur in Brazil.

**Spraying and dusting lima beans on Long Island, H. S. CUNNINGHAM** (*Farm Res. [New York State Sta.]*, 8 (1942), No. 1, pp. 5-6, fig. 1).—A brief summary of recent observations and studies showing that diseases and pests may be readily held in check with well-timed sprays and dusts. Comparisons of several bordeaux formulas with fixed copper preparations indicated very little difference in effectiveness among them.

**Prevention of rotting of melons in transit is purpose of tests undertaken by station, W. A. KREUTZER and D. P. GLICK** (*Colo. Farm Bul. [Colorado Sta.]*, 3 (1941), No. 4, pp. 8-9, fig. 1).—This note reports a rotting of honeydew melons showing up in transit and found due to anthracnose (*Colletotrichum lagenarium*). It is believed that the inoculum came from use of washing tanks and belts for some days without disinfection.

Experiments in control of onion-smut (*Urocystis cepulae* frost), J. G. GIBBS, G. T. S. BAYLIS, and L. BLACKMORE (*New Zcal. Jour. Sci. and Technol.*, 22 (1940), No. 34, pp. 162A-166A, fig. 1).—In tests of formalin drip treatments, all reduced infection by 50-75 percent. No single formula was outstanding in efficacy, but 1-1.6 percent was in general superior to 0.8 percent formalin. Formaldehyde dusts, Agrosan, Ceresan, calomel, and lime-sulfur, as well as attempts at eradication by chemical disinfection of the soil, all proved unsatisfactory.

Reaction of pea varieties to *Septoria pisi*, W. J. ZAUMEYER. (U. S. D. A.). (*Phytopathology*, 32 (1942), No. 1, pp. 64-70).—*S. pisi* was inoculated into 134 strains and varieties of peas in the field (1936-39) to determine their relative resistance and susceptibility. Only 2 varieties exhibited a very high degree of tolerance, particularly canning strains of the Perfection type. In general, the earlier varieties were more susceptible and the later varieties more tolerant.

Cuprous oxide as a seed protectant for peas, L. OGILVIE, H. E. CROXALL, and C. J. HICKMAN (*Univ. Bristol. Agr. and Hort. Res. Sta., Long Ashton, Ann. Rpt.*, 1939, pp. 88-99).—Previous literature (18 references) on pre-emergence damping-off and its control by cuprous oxide is reviewed. Greenhouse and field tests indicated that an increased emergence of seedlings under certain environal conditions may be obtained by such treatment of seeds, comparing favorably with organic mercurials. Evidence is presented that cuprous oxide may retard the rate of seedling emergence, and in dry soils may injure certain varieties.

Doenças do tomateiro no nordeste [Tomato diseases in northeastern Brazil], J. A. DESLANDES (*Bol. Soc. Brasil. Agron.*, 3 (1940), No. 4, pp. 443-452, figs. 12).—A brief conspectus of the diseases and their control.

Curly top control methods, M. SHAPOVALOV. (Utah Expt. Sta. coop. U. S. D. A.). (*Utah Agr. Col. Ext. [Cir.] 109 n. ser.* (1941), pp. 24-25).—A progress report of tomato investigations on this virus disease.

Protecting orchard crops from diseases and insects in eastern New York, C. R. CROSBY, W. D. MILLS, and J. A. EVANS (*N. Y. State Col. Agr., Cornell Ext. Bul. 314, rev.* (1941), pp. 101, figs. 26).

Pot experiments on bitter pit of apples, T. WALLACE and J. O. JONES (*Univ. Bristol, Agr. and Hort. Res. Sta., Long Ashton, Ann. Rpt.*, 1939, pp. 79-84).—Injection tests with various "major" and "minor" elements and citric acid were carried out on potted apple trees (Bramley Seedling) to study any possible relationships with bitter pit. This trouble was severe under all treatments, and it is concluded that the elements and compounds concerned would be ineffective in control. Of the elements used, only Co and Ni caused appreciable injury to the trees. Field tests also indicated the ineffectiveness of boric acid and iron citrate for controlling bitter pit and cork in pears.

Notes on the use of certain sulphur preparations in apple spraying, R. W. MARSH (*Univ. Bristol., Agr. and Hort. Res. Sta., Long Ashton, Ann. Rpt.*, 1939, pp. 42-51).—The types, properties, and applications of a number of sulfur sprays are briefly described, and their usage in the United States is discussed. The few published results of trials in England indicate that the sulfur pastes and dusts are somewhat inferior to lime-sulfurs yielding equivalent S deposits. Though lime-sulfur is usually more phytocidal, the other sulfur products do not obviate spray damage.

Peach tree injury, F. P. CULLINAN. (U. S. D. A.). (*Va. State Hort. Soc. Rpt.*, 45 (1940), pp. 111-117).—Notes on winter injury, with special reference to collar injury in 1940 in Maryland and Virginia.

Notes on the incidence of plum bacterial canker in relation to methods of propagation, R. W. MARSH and T. SWABBRICK (*Univ. Bristol. Agr. and Hort*

*Res. Sta., Long Ashton, Ann. Rpt., 1939, pp. 85-87*).—Tentative conclusions from the observations recorded are that in low-worked trees Kentish Bush is a satisfactory rootstock for both Victoria and Giant Prune, and the latter on this rootstock showed marked resistance to bacterial canker. Giant Prune top-worked on young Pershore trees made satisfactory growth, but top-working of Victoria on Pershore gave trees lacking vigor.

**Red core disease of the strawberry**, R. D. REID (*Scot. Jour. Agr.*, 23 (1941), No. 3, pp. 264-272).—This is a historical and general account of the disease due to *Phytophthora fragariae*, with special reference to its occurrence and importance in Great Britain. After 8 yr. of test and the gradual elimination of unsatisfactory seedlings, five varieties have been released which are said to be very highly resistant to this disease, though less satisfactory with respect to virus diseases. The fruiting characters of these varieties are summarized.

**Angular leaf spot of Muscadines, caused by *Mycosphaerella angulata* n. sp.**, W. A. JENKINS. (Ga. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 1, pp. 71-80, figs. 2).—Studying the symptomatology and etiology of the disease here designated "angular leaf spot" for two seasons, the lesions were found to appear first as small chlorotic areas on the upper leaf surface, rapid development resulting in the production of lesions visible on both leaf surfaces and surrounded by halos on the upper surface. The halos tended to disappear with age. The disease is believed to be coextensive with muscadine culture in the Southeast. The pathogen was observed producing spermatogonia and perithecia in addition to conidia of the previously known *Cercospora brachypus*. The perfect stage, apparently not previously described, is designated *M. angulata* n. sp. Results from one season's work indicate that infection may be controlled by properly timed applications of a 4-5-50 bordeaux spray, and strict vineyard sanitation may prove an important supplement. On the basis of observation alone, it is suggested that judicious selection of resistant breeding stock may be expected to produce more resistant progenies of superior-quality muscadines.

**O tratamento da leprose dos citruss [Control of citrus leprosis]**, A. A. BITANCOURT (*Biologico*, 7 (1941), No. 6, pp. 149-152).

**A poda da laranjeira no tratamento da leprose [The pruning of orange trees for leprosis control]**, S. FRANCO DO AMARAL (*Biologico*, 7 (1941), No. 7, pp. 183-186, figs. 4).

**A podridão das radículas dos citruss na Provincia de Corrientes, Argentina [Root rot of citrus in the Province of Corrientes, Argentina]**, A. A. BITANCOURT (*Biologico*, 6 (1940), Nos. 10, pp. 285-288; 12, pp. 356-364, pls. 4, fig. 1; 7 (1941), No. 3, pp. 62-69).—This presents a general study of the disease, including its history, geographical distribution, symptoms, species of citrus affected, theories as to the cause, and treatment by inarching and grafting.

**La verrucosis de los citricos [Citrus verrucosis]**, G. L. FAWCETT (*Rev. Indus. y Agr. Tucumán*, 30 (1940), No. 10-12, pp. 227-229, figs. 3).—A note on sour orange scab and sweet orange fruit scab and their control in Argentina.

**The establishment of a home-made cuprous oxide mixture as a citrus fungicide in southern Queensland**, F. W. BLACKFORD (*Queensland Agr. Jour.*, 56 (1941), No. 1, pp. 4-33, figs. 3).—In citrus field experiments with a cuprous oxide mixture prepared from  $\text{CuSO}_4$ ,  $\text{NaOH}$ , and molasses or honey in comparison with bordeaux mixture, the former did not seem to injure the trees in the manner commonly associated with bordeaux, and brown spot (*Gloeosporium* sp.) black spot (*Phoma citricarpa*), melanose (*Diaporthe citri*), and scab (*Sphaeceloma fawcettii scabiosa*) were satisfactorily controlled. By modifying the

original formula the mixture may be added to sprays containing soaps and/or white oil. Trees sprayed with the cuprous oxide mixture may be fumigated sooner after spraying than when bordeaux is used. Comprehensive spray schedules for Queensland are presented. There are 32 references.

**Brown rot control and copper injury: Report of a field experiment on lemons,** H. I. MORRIS, L. J. KLOTZ, and V. P. SOKOLOFF. (Calif. Citrus Expt. Sta. et al.). (*Calif. Citroy.*, 26 (1941), No. 10, p. 284, fig. 1).—Experiences with different concentrations of bordeaux spray indicated that thorough coverage with a dilute mixture (1-1-100) will give satisfactory control of brown rot on lemons, and though adding 5 lb. of  $ZnSO_4$  failed to increase its fungicidal effectiveness it did in some manner decrease the tendency to Cu injury. Analytic data showed that injuries to the rind surface are associated with high Cu content of the necrotic tissue derived presumably from the Cu sprays.

**Diseases affecting species *Delphinium*,** T. LASKARIS (*Delphinium* [Amer. *Delphinium Soc.*], 1940, pp. 68-74, figs. 4).—Brief notes on some eight diseases, with special emphasis on a progress report of work on the *Sclerotium delphini* crown rot and its control.

**A new bacterial disease of poinsettia,** P. P. PIRONE and T. R. BENDER (*New Jersey Stas. Nursery Disease Notes*, 14 (1941), No. 4, pp. 13-16).—This disease, shown to be due to an undetermined species of bacterium, is reported to be more destructive than the *Rhizoctonia* stem rot which hitherto has been the most serious disease of poinsettia.

**Os mosaicos da roseira no Estado de S. Paulo [Mosaics of roses in São Paulo, Brazil],** M. KRAMER (*Biologico*, 6 (1940), No. 12, pp. 365-368, pls. 2).—On rose mosaic and rose yellow mosaic.

**A virosis-like injury of snapdragon caused by feeding of the peach aphid,** K. F. BAKER and C. M. TOMPKINS. (Univ. Calif.). (*Phytopathology*, 32 (1942), No. 1, pp. 93-95, fig. 1).—Both under greenhouse and field conditions in California, *Myzus persicae* was found to cause a virosislike injury of the terminal growth of *Antirrhinum majus*, resulting in a reduction in size and frequent distortion of the leaves, accompanied by yellow or white blotches or spots usually along the midribs near the leaf bases. The symptoms were also observed on five other species of *Antirrhinum* and on *Linaria dalmatica*. That the condition was not virus-induced was indicated by the facts that when freed of aphids new growth from injured plants was normal, that a nonviruliferous line of aphids induced typical injury, and that only the leaves fed upon exhibited the abnormal condition.

**Tulip fire (*Botrytis tulipae*),** a disease new to the country, J. B. MARCOTTA (*Internatl. Bul. Plant Protect.* [Roma], 15 (1941), No. 7-8, p. 133M).—A note on this disease of tulip in Argentina.

**A *Xylaria* pathogenic to *Ginkgo biloba* L. seeds,** S. H. DAVIS, JR., and J. B. HARRY (*Phytopathology*, 32 (1942), No. 1, pp. 91-93, figs. 2).—A fungus isolated from dying ginkgo branches was identified as *X. longeana*. Inoculating it into sterile and nonsterile soil at the time of sowing ginkgo seeds resulted in about 95 percent pre-emergence loss, and survivors produced only stunted seedlings.

**Bleeding canker of maples,** N. CAROSELLI and F. L. HOWARD. (R. I. Expt. Sta.). (*Bartlett Tree Res. Labs. Bul.* 3 (1939), pp. 44-48, figs. 3).—This paper is a summary of the authors' work on the disease first noted about 1930 and shown by them to be due to *Phytophthora cactorum*. The distribution, maple species attacked, and etiology are here considered.

**Antidoting toxin of *Phytophthora cactorum* as a means of plant disease control,** F. L. HOWARD. (R. I. Expt. Sta.). (*Science*, 94 (1941), No. 2441, p. 345).—Over 350 maple (?) trees, naturally infected by the bleeding canker

fungus, after injection with 0.5 percent aqueous solution of the dihydrochloride salt of diaminooazobenzene plus a solvent and penetrant ("Hellone orange") stopped "bleeding" and showed marked improvement in vegetative growth. This chemical, when added to the toxic filtrate from cultures of the fungus, prevented injury from its injection into healthy trees. Whether the chemical will eliminate infection from trees is not yet known.

**Distribution and suggested control measures for the southern pine fusiform rust**, II. LAMB and B. SLEETH (*U. S. Dept. Agr., Forest Serv., South. Forest Expt. Sta. Occas. Paper 91 (1940), pp. [21]+5, fig. 1*).—This paper summarizes the situation. Slash and loblolly pines and the black oak group are said to be the most susceptible to the pine-oak rust (*Cronartium fusiforme*), the approximate range of which in the Southeastern States is discussed and mapped. The mortality from infection is highest in the pine seedling stage and least in the mature stand. Control depends mostly on the prevention of infection in the nursery and removal of cankered branches from young trees in the field before infection reaches the trunks.

**Some nematodes of the family Tylenchidae which do not possess a valvular median esophageal bulb**, G. THORNE (*U. S. D. A. (Great Basin Nat., 2 (1941), No. 2, pp. 37-85, pls. 9*).—"The collection of nematodes on which this paper is based has accumulated at the Salt Lake City Station of the Division of Nematology during the past 20 yr. These specimens have been secured from the great quantity of plant and soil material submitted for examination and identification by various State, Government, and private agencies and from the extensive faunistic collections made at this station." New taxonomy and keys to the groups are included. There are 23 references.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

**Game bird investigations: Quail and chukar partridges**, E. M. FUNK, J. C. HAMILTON, and II. L. KEMPSTER (*Missouri Sta. Bul. 435 (1941), pp. 16, figs. 7*).—In experiments conducted in 1938 and 1939 on the effect of all-night light on quail and chukar partridges the total egg production of these fowl was increased. The larger egg production for the lighted birds was attributed to a longer laying period due to early egg production and also to a higher rate of production. The results obtained on variation between individual quail suggest the possibility of breeding for increased fertility and hatchability. Based on a single trial, flock matings of chukar partridges produced more satisfactory results than did mating in pairs. Best results were obtained when one male was mated to four females. In captivity a male quail will mate with more than one female. Eggs from flocks where one male was mated with two females showed a fertility of 97.97 percent. Maintaining breeding chukar partridges on earth floors resulted in a higher percentage of fertility and hatchability than was experienced when birds were maintained on wire floors. Chukar partridges produced eggs of average size after the first week of laying. Quail laid eggs of average size in their fifth week of laying. Hot weather apparently does not have the depressing effect on egg weight in quail and chukar partridges which is experienced in chickens. Quail and chukar partridge eggs increased in size each succeeding month, whereas the weight of chicken eggs declined to a low point in July. The weight of chukar partridge and quail eggs was influenced by the position of the egg in the clutch. The largest egg was usually the first egg in the clutch. Results indicated that an increase of egg production in quail and chukar partridges was accompanied by an increase in the size of clutch. The average chukar partridge egg was 22.37 gm. in weight, 4.207 cm. in length, and 3.154 cm. in width. The average quail egg was 9.13 gm. in weight, 3.095 cm. in length, and 2.401 cm.

in width. Chukar partridges under all-night lights consumed an average of 5 lb. of feed per pair for each month of the breeding season. The unlighted birds ate an average of approximately 4 lb. of feed per pair for each month. Each pair of all-night lighted quail ate 2.15 lb. of feed, whereas each pair of unlighted quail ate 2.05 lb. per month.

**The handbook of British birds, I-V, H. F. WITHERBY, F. C. R. JOURDAIN, II. F. TICEHURST, and B. W. TUCKER** (*London: H. F. & G. Witherby, 1938, vols. 1, pp. XI+326, pls. [33], figs. [54]; 2, pp. XIII+352, pls. [30], figs. [48]; 1939, vol. 3, pp. X+387, pls. 39, figs. [53]; 1940, vol. 4, pp. XIV+461, pls. [33], [figs. 85]; 1941, vol. 5, pp. XII+356, pls. 22, [figs. 72]*).—This work, which succeeds *A Practical Handbook of British Birds*, issued from 1920 to 1924 (E. S. R., 51, p. 54), has been largely rewritten (in five volumes), remodeled, and much new matter added, more especially on the life history of the birds. Volume 1 takes up crows to flycatchers; 2, warblers to owls; 3, hawks to ducks; 4, cormorants to cranes; and 5, terns to game birds. Included in volume 5 are additions and corrections to the work, a systematic list of British birds, and indexes.

**The role of territory in bird life, M. M. NICE** (*1mer. Midland Nat., 26 (1941), No. 3, pp. 441-487*).—Presented with a bibliography of 16 pages.

**[Investigations in economic zoology and entomology by the Alabama Station] (Alabama Sta. Rpt. 1940, pp. 42-43, 44-45)**.—This report notes progress (E. S. R., 85, p. 499) in studies on the relative efficiency of rotenone-containing insecticides in the control of vegetable-crop insects, by F. S. Arant; the fumigation of camellias and azaleas with methyl bromide, by L. L. English; and farm fish ponds, by H. S. Swingle and E. V. Smith.

**The endocrine control of insect development, E. T. BURR** (*In Abstracts of Dissertations Approved for the Ph. D., M. Sc., M. Litt. Degrees in the University of Cambridge During the Academical Year 1939-1940. Cambridge, Eng.: Univ. Press, 1941, pp. 21-22*).

**[Notes on economic insects and their control] (Jour. Econ. Ent., 34 (1941), No. 6, pp. 859-861)**.—Contributions presented (E. S. R., 86, p. 352) are: Susceptibility of Resistant and Nonresistant Strains of the California Red Scale to Sprays of Oil and Cube Resins, by A. W. Cressman (p. 859) (U. S. D. A.); Chemical Control of *Pseudococcus comstocki* Kuw., by W. M. Upholt (pp. 859-860) (S. C. Expt. Sta.); Control of the Euonymus Scale, by L. Pycnson (p. 860); and Action of Derris and Rotenone on the Firebrat, by C. H. Richardson and E. J. Selferle (pp. 860-861) (Iowa Sta.).

**[Work in economic entomology by the Colorado Station] (Colorado Sta. Rpt. 1941, pp. 23-26)**.—The work of the year (E. S. R., 84, p. 642) relates to a cactus-destroying insect, *Monilema annulata* Say and its control, insect transmission of peach mosaic, insecticide tests with cucurbit insects, and effect of treatments for psyllid infestations of tomatoes on spoilage in storage.

**Current contributions on insect control (New York State Sta. Bul. 698 (1942), pp. 62, figs. 9)**.—Included are the following: Present Status of the Mineral Oil Treatment for Corn Ear Worm Control, by L. A. Carruth (pp. 3-5); The Status of Biological Control of the Japanese Beetle in New York State, by E. H. Smith and D. M. Daniel (pp. 6-9); Pyrethrum Dusts for the Control of the Apple Redbug, by R. W. Dean (pp. 10-11); The Use of Concentrated Sprays for Pea Aphid Control, by H. Glasgow (pp. 12-14); Blood Albumin for Use as an Emulsifier, by G. W. Pearce and P. J. Chapman (pp. 15-16); Contributions to Codling Moth Control, by S. W. Harman (pp. 17-19); Squash Vine Borer Control, by G. E. R. Hervey (pp. 20-21); Dormant Treatments for the Control of Certain Insects on Nursery Plants, by F. L. Gambrell (pp. 22-25);

Relation of Oil Deposits to the Control of the Oriental Fruit Moth on Quinces, by E. H. Smith, A. W. Avens, and S. C. Mendall (pp. 26-28); Insecticidal Control of the Raspberry Cané Borer, by F. G. Mundinger (pp. 29-30); Pea Aphids as a Factor in Growing Peas on Long Island, by H. C. Hockett (p. 31); A Shortened, Intensive Summer Spray Program for Apples in Eastern New York, by O. H. Hammer and D. W. Hamilton (pp. 32-34) (coop. U. S. D. A.); Use of Dusts for European Corn Borer Control, by L. A. Carruth (pp. 35-39); A New Basis for Selecting Petroleum Oils for Orchard Sprays, by P. J. Chapman, G. W. Pearce, and A. W. Avens (pp. 40-42); Recent Investigations on Cherry Fruitflies [Cherry Fruitfly and Black Cherry Fruitfly], by D. W. Hamilton (pp. 43-44) (U. S. D. A.); Studies on the Control of the Grape-Berry Moth, by E. F. Taschenberg and F. Z. Hartzell (pp. 45-47); Studies of Rotenone Sprays for Cabbage Worm Control, by G. E. R. Hervey (pp. 48-50); Recent Experiments to Control the Scurfy Scale, by O. H. Hammer (pp. 51-52); Insecticides for Oriental Fruit Moth Control, by R. W. Dean and E. H. Smith (pp. 53-54); Field Identification of Five Leaf Rollers [the Fruit Tree Leaf Roller, *Pandemis limitata* Robinson, the Oblique-Banded Leaf Roller, *Eulia quadrifasciana* Fern., and *E. velutinana* Walk.] Found in Apple Orchards, by D. E. Greenwood (pp. 55-58); and Pre-foliage Treatments for Control of [Eye-Spotted] Bud Moth, by F. Z. Hartzell (pp. 59-62).

The effect of host density on the rate of reproduction of entomophagous parasites, P. DE BACH and H. S. SMITH. (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 741-745, fig. 1).—Using housefly puparia distributed at random in a container filled with barley, an investigation was made of the success of two species of parasites, *Mormoniella vitripennis* (Walk.) and *Muscidifurax raptor* Gir., in the search for hosts. It was demonstrated that *Mormoniella* found hosts at a rate which increased with increasing host density, but which was not constant and which finally approached a fixed rate asymptotically. This deceleration of the rate at which discovery increased with host density appeared to be caused by the increasingly greater proportion of time spent in nonsearching activities as the host density increased. These nonsearching activities are mainly oviposition, feeding, and resting. *Muscidifurax* has such great searching ability in comparison with *Mormoniella* that under the conditions of the experiment all the hosts were found at the lower densities. These experiments were restricted to single "generations" and a constant parasite density. The experiment is considered to illustrate the importance of searching capacity, as opposed to potential reproductive capacity, in the determination of a parasite's efficiency.

Studies of insect damage to cotton with reference to soil-conservation practices, P. A. GLICK and K. P. EWING. (U. S. D. A.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 737-741).

Isolation-cage studies of certain hemipterous and homopterous insects on sugar beets grown for seed, O. A. HILLS. (U. S. D. A.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 756-760, figs. 2).—Surveys of fields of sugar beets grown for seed in Arizona having indicated the presence of certain insects likely to be of economic importance in the Southwest, cage studies were conducted in 1938 and 1939. These revealed that *Lygus* spp., Say's stinkbug, and *Thyanta custator* (F.) are capable of materially reducing the percentage of viable sugar beet seed produced per plant. The number of seed balls was not reduced by these insects, but the seed was slightly lighter in weight, as was indicated by a reduction in weight per unit of volume. The false chinch bug up to 500 per plant had no measurable effect on the quantity or quality of seed produced. Heavy infestations of the green peach aphid in cages drastically reduced the quantity of seed produced but did not significantly reduce the viability.

**Boll weevil and cotton aphid control by the use of derris in combination with calcium arsenate**, C. F. RAINWATER and F. F. BONDY. (U. S. D. A.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 733-735).—Report is made of identical experiments conducted at Florence, S. C., State College, Miss, Tallulah, La., and Waco, Tex., in 1940 in which four insecticides or combinations of insecticides were tested against the bollweevil and the cotton aphid. Calcium arsenate was tested with and without derris at the rate of 6 lb. per acre per application and equal parts of calcium arsenate and sulfur with and without derris at the rate of 12 lb. per acre per application. Eight effective applications were made at each location. Analysis of the data showed that there was no significant difference in the degree of bollweevil control between any two insecticides and that each insecticide was significantly better than the check. Aphid population counts showed highly significant differences favoring the insecticides which contained derris over those which did not. Yield records showed that calcium arsenate plus derris was significantly better than calcium arsenate alone.

**A method of stimulating airplane application of insecticides to tall plants in experimental plots**, O. A. HILLS and V. E. ROMNEY. (U. S. D. A.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 853-856, figs. 5).—The equipment and technic developed for use in the application of any insecticide by airplane to sugar beets grown for seed, as in the Salt River Valley of Arizona, are described.

**The distribution of sodium arsenite and diluent in the dust cloud**, E. HASTINGS and J. H. PEPPIE (Mont. Expt. Sta.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 769-772, fig. 1).—Report is made of an investigation of the purely physical manner in which a dust diluent of sodium arsenite may affect its value as a contact insecticide for the mormon cricket. The work conducted has led to the conclusion that no interaction took place between the diluents and the active ingredient used, and further that the composition of a dust cloud obtained from the use of the mixed dusts is dependent upon particle size. However, if densities of the materials in a dust mixture varied considerably this, as well as particle shape, would have to be considered.

**Some recent advances in the chemistry and physics of spray oils and emulsions**, W. M. HOSKINS. (Univ. Calif.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 791-798, figs. 2).—Summarizing the discussion presented, it is pointed out that an increasing number of synthetic wetting and emulsifying agents are available, most of which are of doubtful value in oil sprays because they reduce deposit. Under the influence of solubilizing agents oil becomes soluble to a marked extent in aqueous solutions, and the same phenomenon occurs with "insoluble" substances in oil as a solvent in the presence of the proper solubilizer. The spreading of oil upon water is promoted, and penetration into foliage is retarded by small concentrations of semipolar compounds. On the other hand, inert hydrocarbons such as oils seem to assist semipolar toxic compounds, for instance alcohols, in penetrating insect integument. Lastly, oxidation of unsaturated hydrocarbons to form complex acids is chiefly responsible for leaf injury. The unsulfonatable residue test is not always a satisfactory criterion for estimating the tendency to oxidize, but a practical substitute test is yet to be found.

**See chemical composition of oils affecting efficiency**, P. J. CHAPMAN, G. W. PEARCE, and A. W. AVENS (*Farm Res. [New York State Sta.]*, 8 (1942), No. 1, pp. 1, 3, fig. 1).—A practical account, continuing previous work (E. S. R., 86, p. 215).

**Methods of measuring spray oil deposits**, A. W. CRESSMAN. (U. S. D. A.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 798-804, figs. 2).—A review of various methods of measuring deposits of spray oils has shown that all except one colori-

metric analysis involve extraction of the oil from the sprayed surface with a suitable solvent, evaporation of the solvent, and either volumetric or gravimetric measurement of the extracted oil. Both whole leaves and disks of known area have been used. Although the distribution of oil may not be uniform over the whole leaf, the disk method of sampling is considered adequate for measurement of relative results. Rapid loss of oil following application of field sprays necessitates either prompt extraction or storage of samples at low temperatures. It is doubtful whether relative deposits in field sprays can be inferred directly from laboratory measurements, since differences in the surfaces or conditions of application may change the relative quantities of oil deposited by different sprays.

**Physiological effects of petroleum oil sprays on citrus, P. W. ROHRBAUGH** (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 812-815, figs. 6).—It is pointed out that the injurious effects of petroleum spray oils on citrus are now considered to be largely due to two factors. The first factor is a chemical burning by the unsaturated hydrocarbon molecules or other toxic molecules in the oil. The second factor in injury to citrus by oil sprays seems to be the result of the plugging of the intercellular spaces and the surrounding of the plant cells with oils which prevent the movement of gases such as carbon dioxide and oxygen out of and into the cells.

**Solubilizers for petroleum oils and extracts of rotenone-bearing roots, J. F. KAGY and A. M. BOYCE** (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 804-811, figs. 5).—A method for the determination of the miscibility of ternary systems, rotenone-bearing extracts—petroleum oils—solubilizers, is prescribed. "For any solubilizer a series of plait points were determined experimentally. By plating these values on triangular coordinate paper, curves are obtained which delimit homogeneous and heterogeneous mixtures. Three-component solubility curves have been determined for systems of a light-medium oil—derris extract (33 percent rotenone)—solubilizers that are representative of different chemical classes. The solubilizers included in the study were diphenyl oxide, oil of sassafras, methyl-*n*-amyl ketone, dibutylphthalate, 2(4-*tert*-butylphenoxy) ethanol, Cardolite, and diamylphenol. The effect of the grade and unsulfonatable residue (U. R.) of the petroleum oil on the miscibility of the three components of the ternary systems has been determined. The lower the U. R. value of the same grade of oil the greater the amount that can be added to a given solution of solubilizer plus extract. The more volatile fractions of the kerosene grade have greater relative compatibility with extract-solubilizer solutions than the heavier fractions. It has been found that the compatibility of extracts of rotenone-bearing roots that differ in source is not a function of the rotenone content. Chemically pure rotenone is much more soluble in solutions of a light-medium petroleum oil and 2(4-*tert*-butylphenoxy) ethanol than similar quantities of rotenone in the presence of the other constituents of the extract. It has been suggested that some constituent in the extract other than rotenone is the chief factor in determining the compatibility of the mixtures.

"The desirability of knowing the composition of the phases that separate in the state of heterogeneity of the systems has been stressed. Within certain ranges of concentrations of the systems a phase separates what appears to be one or more of the ethylenedichloride-soluble resins of the root. Toxicological evidence points to the fact that certain heterogeneous compositions are effective for the control of certain insects, possibly because the active constituents of the extract are in solution.

**Physiological and physical effects of spray oils on deciduous trees, P. A. YOUNG** (Tex. Expt. Sta.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 838-844).—

A brief review is given of all available parts of the extensive recent literature on the effects of petroleum and tar oils on sprayed plants, especially deciduous fruits, together with a list of 59 references. Herbaceous plants are mentioned for comparison and accessory information.

**Toxicants used with petroleum oil sprays for deciduous fruits, L. M. SMITH.** (Univ. Calif.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 844-853).—The toxicants used with petroleum oil sprays here considered are grouped into (1) insecticides of plant origin, (2) synthetic organic insecticides, and (3) inorganic insecticides. A list of 74 references is included.

**Materials added to oil spray to increase its effectiveness in citrus pest control, W. EBELING.** (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 829-837).—Materials increasing the effectiveness of oil spray (1) by physical and (2) by chemical means are dealt with. Materials added to oils may result in improvement of the resulting sprays by (1) making possible the treatment of two pests requiring different insecticides with one spray treatment, (2) increasing the effectiveness of the spray because of the additive effect of the independent actions of two or more insecticides, (3) increasing the effectiveness of the spray because of the apparent synergistic action often resulting from combinations of certain compounds with oil even though these compounds may by themselves have little or no insecticidal value against the pest in question, and (4) by making possible the penetration of compounds which have a high independent toxicity but are not able to penetrate to the insect or into its body. Examples of materials added to petroleum oil spray which have been used either experimentally or in actual citrus pest control practice are (1) cryolite in orange tortrix and *Holcocera iceryaella* control, (2) Selocide and wettable sulfur in citrus red mite control, (3) various sulfur compounds in citrus red mite and citrus bud mite *Eriophyes sheldoni* control, (4) lime-sulfur used with miscible oil in control of unarmored scale insects and citrus red mite, (5) nicotine sulfate in greenhouse thrips control and nicotine in California red scale control experiments, (6) pyrethrum in greenhouse thrips control, (7) dinitro-*o*-cyclohexylphenol in scale control experiments, (8) Lethane in black scale and California red scale control experiments, (9) preparations including ground rotenone-bearing roots in black scale control, and (10) the extractives of rotenone-bearing plants incorporated into oil by means of solubilizers and used in the control of scale insects.

**Comparative effects of oil spray and hydrocyanic acid fumigation on the composition of orange fruits, W. B. SINCLAIR, E. T. BARTHOLOMEW, and W. EBELING.** (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 821-829, fig. 1).—It was found that the spraying of citrus trees with light-medium oils in concentrations of 0.25 to 1.75 percent caused a reduction in the total soluble solids and in reducing and total sugars of the fruit juice. Oil sprays with and without the toxicants were equally effective in reducing the soluble constituents in the fruit. Although oil spray had a tendency to reduce the titratable acidity, the results were not so decisive as in the case of the other soluble constituents. Since orange juice is highly buffered, the small change in titratable acidity of the juice was not sufficient to produce an effective change in pH of the mature fruit. Only slight differences occurred in the composition of the juice of fruits from plats that had been sprayed with 0.75 to 1.75 percent oil. The data show that although the groves of these experiments were widely separated and differed greatly as to environmental conditions and soil types, the change effected by the spray in chemical composition of the fruit was practically the same. The time of the year at which the oil was applied was found to be relatively unimportant. The fumigation of citrus trees with HCN

either in the fall or in the winter had no marked effect on the chemical composition of the mature fruit.

**Factors affecting the absorption and retention of hydrocyanic acid by citrus leaves and fruits,** E. T. BARTHOLOMEW, W. B. SINCLAIR, and D. L. LINDGREN. (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 815-821, figs. 5).—It was found that green and mature fruits absorbed decreasingly less HCN when preconditioned overnight at 43°, 50°, 65°, and 80° F. Fruits sprayed with a 1 percent oil spray in the laboratory absorbed less HCN than unsprayed fruits, but similar tests with a 1.5 percent oil spray in the field showed no appreciable difference. Turgid fruits and leaves absorbed more HCN than nonturgid fruits and leaves under field conditions, but not under laboratory conditions. Fruits from coastal areas absorbed more HCN than similar fruits from inland areas in 1939-40 but less in 1940-41. In both years, however, the coastal fruits were more seriously injured than the inland fruits. The amounts of HCN absorbed by fruits and leaves when fumigated under field conditions during the day or at night were approximately the same, but fruits and leaves fumigated during the day were much more severely injured than those fumigated at night. These results indicate that the stomata are not a controlling factor in HCN absorption. Whether or not the fumigated tissues will be injured appears to be governed by the physiological condition of the tissues more than by the amount of HCN absorbed.

**The behavior of hydrocyanic acid gas under a fumigation tent,** R. A. FULTON, R. L. BUSHEY, and H. R. YUST. (U. S. D. A.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 777-783, figs. 5).—A study of the behavior of HCN gas under a form tent over an orange tree, its distribution being determined by various methods, is reported upon. It was found that all the methods produced locations of low concentration, especially near the periphery of the tent. The concentration of the gas varied sufficiently to produce significant differences in mortality of scale insects. A means for reducing this variation by first diluting the HCN with air by means of a blower inside the tent was developed. This improvement is supported by chemical analyses and by the tests of mortality of scale insects placed at several locations in the tent. Adequate distribution of the gas was also obtained with the dilution device when trees in a lemon grove were covered with regular fumigation tents.

**Preliminary experiments on the silverfish *Otenolepisma urbani* Slabaugh,** A. MALLIS. (Univ. Calif.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 787-791).—Report is made of a study of the behavior of *C. urbani* as related to means for its control.

**Laboratory control studies on the greenhouse thrips,** B. R. BARTLETT and C. O. PERSING. (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 760-766).—In laboratory control studies of the greenhouse thrips on the Valencia orange, tests were made of a number of sprays and dusts against the adult stage at concentrations likely to be practicable for field usage on citrus. The adults were readily killed by a number of materials in sprays and dusts. Pyrethrum was extremely toxic, and sprays containing nicotine sulfate and dusts of 2,4-dinitro-6-cyclohexylphenol were also very effective. Certain antimony and fluorine stomach poisons used with sucrose were tested on the adult stage, and none was found to be effective enough to offer much promise. The antimony compounds were more effective than the fluorine materials, and tartar emetic was the most promising of the antimony compounds.

Various materials were tested against eggs of the greenhouse thrips. A comparison of the effectiveness of certain spray oils shows that an appreciable mortality of eggs occurred when highly refined light-medium petroleum oil was

used at 1.67 percent. Kerosene used at 8 percent had little effect. Comparisons of the effectiveness of spray mixtures of highly refined light-medium petroleum oil with nicotine sulfate solution and pyrethrum extract indicated that pyrethrum extract with petroleum oil was approximately eight times as effective as nicotine sulfate and petroleum oil. Numerous other materials were tested in sprays, with and without oil, against eggs of this species. The most effective materials, other than pyrethrum extract, were 2,4-dinitro-6-cyclohexylphenol and the dicyclohexylamine salt of this compound. A spray mixture containing 0.5 percent of a highly refined light-medium petroleum oil and sulfur was also effective, but sulfur alone was not.

**Observations on the biology and control of the treehopper *Heliria pracalta* (Fowler) in orchards of the Pacific Northwest.** M. A. YOTHERS and P. B. ALLEN, JR. (*U. S. Dept. Agr. Cir. 606* (1941), pp. 12, pls. 5, figs. 4).—Studies were made on the biology and control of the membracid *H. pracalta* near Wenatchee, Wash., from 1929 to 1934, inclusive. This potential apple pest was first found in the West on apple in 1914. Eggs are deposited throughout July and August in the bark of branches and sprouts of apple trees. The eggs hatch in late April or early May. Nymphs pass through five instars and reach maturity about June 1. Adults are present from the last of May until the first of October. Only one generation occurs annually. Control methods suggested include pruning off the water sprouts, in the base of which most eggs are deposited, and spraying with a 4 percent dormant oil emulsion and possibly the use of an emulsion of nicotine and summer oil for control of the early nymphal stages.

**A review of the Aleyrodidae of Mexico.** W. W. SAMPSON and E. A. DREWS (*An. Escuela Nac. Cien. Biol. [Mexico]*, 2, (1940), No. 2-3, pp. 143-180, figs. 24).—Fifty-one species of Aleyrodidae are recorded from Mexico, of which 22 are described as new to science. Two new species are described from Panama.

***Matsucoccus bisetosus* Morrison, a potential enemy of California pines.** H. L. MCKENZIE. (U. S. D. A.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 783-785, figs. 3).—A preliminary survey made of the *Matsucoccus* scale insects in the California region indicates that there are a half dozen or more species that appear to be definitely connected with injury to pines, of which *M. bisetosus* appears to be the most important. This preliminary contribution, based upon information gained during the last 2 yr., considers the effect of the scale on pines, occurrence, and its potentialities as a forest problem.

**A morphological difference between the California red scale and the yellow scale [*Aonidiella citrina* (Coq.)].** H. R. YUST. (U. S. D. A.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 785-787).

**The control of black scale in olive orchards by calcium cyanide dusting.** A. F. KIRKPATRICK (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 772-777, figs. 5).—Dusting work is reported with calcium cyanide for the control of the black scale in the San Joaquin and Sacramento Valleys of California, where approximately 20,000 acres or 82 percent of the commercial olive trees in the United States are located.

**Las cochinillas de los citricos Tucumanos y su control [Scale insects of citrus in Tucumán and their control].** K. J. HAYWARD (*Bol. Estac. Expt. Agr. Tucumán*, No. 32 (1941), pp. [2]+29, figs. 17).

**Relative effectiveness of acid lead arsenate and other materials as stomach poisons for the larvae of the Japanese beetle.** W. E. FLEMING (*U. S. Dept. Agr., Tech. Bul. 788* (1942), pp. 32, fig. 1).—Toxicity tests were conducted in the laboratory during the period from 1929 to 1936, inclusive, with larvae of the Japanese beetle. Acid lead arsenate was used as a standard of insecticidal activity. Freshly applied arsenates of calcium, magnesium, and manganese

appeared more effective than acid lead arsenate; arsenates of aluminum, barium, ferric iron, and zinc appeared equivalent to acid lead arsenate; and basic lead arsenate showed no insecticidal value. The effectiveness of acid lead arsenate, ferric arsenate, and zinc arsenate decreased rapidly after these arsenicals had remained in the soil for about 2 to 3 yr, while the effectiveness of the other arsenicals appeared to last 1 or 2 yr. longer. With the exception of basic lead arsenate, these arsenicals were more toxic to plants than was acid lead arsenate. Arsenious oxide and arsenious sulfide proved more toxic to larvae than acid lead arsenate and were affected slowly by the soil. Both were toxic to plants. Paris green and its homologues were effective as insecticides but harmful to plant growth. Inorganic borates of calcium, lead, magnesium, nickel, sodium, strontium, and zinc were relatively nontoxic to larvae. Inorganic fluorides of aluminum, barium, calcium, copper, lead, magnesium, strontium, and zinc and natural cryolite were not toxic to the larvae. Fluosilicates of barium, magnesium, potassium, and sodium were equal or superior to acid lead arsenate when freshly applied, but their rapid decomposition in the soil to nontoxic compounds or loss of their insecticidal constituents by leaching makes them unsuitable as substitutes for acid lead arsenate. Calcium fluosilicate was nontoxic. Derris, hellebore, mowrah meal, and pyrethrum were slightly toxic. Fertilizers and soil conditioners such as acid phosphate, ammonium sulfate, ground limestone, hydrated lime, and calcium cyanamide were slightly toxic to larvae. It is suggested that some of these materials might be substituted for acid lead arsenate to kill Japanese beetle larvae in soil under conditions where the effect of the material on vegetation is not a limiting factor. When the susceptibility of the plants growing in the soil to chemical injury is a factor acid lead arsenate appeared to be the safest of the larval poisons.

**Control of the locust borer, R. C. HALL.** (Coop. Ohio State Univ. et al) (*U. S. Dept. Agr. Cir. 626 (1942), pp. 19, figs. 14*).—Locust borer control has become more important because of the extensive planting of black locust in the soil conservation programs. These plantings furnish ideal environment for this insect and create conditions favorable for high larval survival and subsequent severe damage. Investigations over a 7-yr. period at Columbus, Ohio, have shown a close relationship between borer damage and tree vigor. Among important factors that reduce tree vigor and increase its susceptibility to borer injury are drought, fire, and grazing of livestock. Silvicultural practices of promise in borer control include clear-cutting, thinning, mulching, mixed planting, and the use of superior varieties of black locust. Clear-cutting is useful in slowly growing stands where later sprout growth developing from stumps is rapid. Thinning is useful in moderately growing stands where the slowly growing and highly susceptible understory trees are removed. Mixed planting is useful for the establishment of new plantations. Mulching is limited to trees of high value. Control other than silvical includes that by natural enemies and by spraying with orthodichlorobenzene, although the latter is considered too expensive for general use.

**Methyl bromide fumigation of strawberry planting stock to control *Paria canella* var. *quadrinotata* (Say), G. S. KMO.** (Univ. Calif). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 766-768).—Fumigation control work in 1939-40 with the strawberry rootworm *P. canella quadrinotata*, one of the major pests of strawberries in the central coast and Sacramento districts in California, is reported upon. It was found that on dormant planting stock control may be effected by fumigation with methyl bromide at the rate of 2 lb. per 1,000 cu. ft. for a 3-hr. period or 3 lb. per 1,000 cu. ft. for 2 hr., at a temperature of 72°-74° F. Definite stimulation in growth was noted for the treated plants.

A chemical study of the bearing of decay by *Phellinus cryptarum* Karst. and other fungi on the destruction of wood by the death-watch beetle *Xestobium rufovillosum* De G., W. G. CAMPBELL and S. A. BRYANT (*Biochem. Jour.*, 34 (1940), No. 10-11, pp. 1404-1414).

Prothetely in *Scolytus multistriatus* Marsham (Coleop.: Scolytidae), R. L. BEARD and P. P. WALLACE. (Conn. [New Haven] Expt. Sta.). (*Ent. News*, 52 (1941), No. 9, pp. 242-244, fig. 1).

Field studies of insecticides used to control cabbage caterpillars in the South, W. J. REID, JR., C. E. SMITH, L. B. REED, and W. A. THOMAS (*U. S. Dept. Agr., Tech. Bul.* 782 (1941), pp. 36, figs. 7).—Results indicate that a derris dust mixture containing from 0.5 to 1 percent rotenone is sufficiently toxic to the three most important species of cabbage caterpillars in the South, the cabbage looper, imported cabbageworm, and diamondback moth, to be of value as a substitute for arsenical insecticides in their control. Pyrethrum powder diluted to contain not less than 0.1 percent of pyrethrin I is of considerable value when directed against the cabbage looper and of some value against the imported cabbageworm. Derris and pyrethrum powders were found relatively ineffective against the Agrotinae (the corn earworm and several species of true cutworms) that are sometimes pests of cabbage and related crops. Cryolite, calcium arsenate, and paris green were effective against the Agrotinae, cryolite against the cabbage looper, calcium arsenate against diamondback moth larvae, and paris green against the imported cabbageworm. Hellebore was relatively ineffective against all species.

Studies on the control of cabbage caterpillars with derris in the South, W. J. REID, JR., C. E. SMITH, L. B. REED, and C. O. BARE. (Coop. La. and S. C. Expt. Stas.). (*U. S. Dept. Agr. Cir.* 615 (1942), pp. 27, figs. 9).—The effectiveness of from one to five applications of a derris-clay dust (0.5 percent rotenone) for reducing caterpillar injury and damage and in increasing the yield of marketable cabbage was studied in a series of nine experiments at Baton Rouge, La., and Charleston, S. C., from the fall of 1935 through the spring of 1937. The principal insects involved were the cabbage looper, diamondback moth, imported cabbageworm and corn earworm. Where spring crops were planted it did not prove profitable to apply the dust until shortly before the beginning of harvest. In the four spring-crop experiments the increase in yield due to the most efficient treatments after allowing for experimental error was at least from 0.8 to 1.79 tons of U. S. grade No. 1 cabbage and the net profit at least from \$14 to \$29 per acre. Fall-crop experiments in 1935 showed a need for the protection of plants against the corn earworm and climbing cutworms during the preheading stages of growth with more toxic material than derris. These experiments indicated the need for protection against the cabbage looper and imported cabbageworm during the heading period and at least a portion of the harvesting period. Five applications of arsenical dusts and one of a poisoned bait followed by two of derris dust provided commercially adequate caterpillar control at Charleston in the 1936 fall-crop experiment and resulted in an increase of at least 1.3 tons of U. S. grade No. 1 cabbage per acre. These investigations indicated a need for similar studies of dusts of greater rotenone content and of the effects of more frequent applications.

Wattle bagworm control by aeroplane dusting, T. J. NAUDÉ, L. B. RIPLEY, and B. K. PERRY (*Union So. Africa Dept. Agr. and Forestry, Sci. Bul.* 206 (1939), pp. 12).—The application of airplane dusting in the control of the wattle bagworm *Acanthopsyche junodi* Heyl. in Natal proved entirely practicable with commercial aircraft available in the Union of South Africa. "The kill in spite of the somewhat crude apparatus employed was well over 95 percent in

the part of the demonstration where normal cryolite dust was used, which must be considered as highly satisfactory. Through this improved method of distribution an application of 20 lb. per acre proved fully as effective as 30 lb. or more applied from the ground by means of power dusters, thus making a very material saving in insecticide possible in favor of airplane dusting. The total cost per acre of airplane dusting, even at a distance of 11 miles from the flying base, compares very favorably with that of ground dusting, the former being between 7 and 8 shillings per acre while the latter costs between 8 and 9 shillings."

**Further studies on gustatory reactions of the wattle bagworm *Acanthopsyche junodi* Heyl.**, L. B. RIPLEY, B. K. PETTY, and P. W. VAN HEERDEN (*Union So. Africa Dept. Agr. and Forestry, Sci. Bul.* 205 (1939), pp. 20, figs. 8).

**Insecticides for bud moth control**, F. Z. HARTZELL (*Farm Res. [New York State Sta.],* 8 (1942), No. 1, pp. 6, 8).—A practical account.

**Secondary hosts of the pink bollworm in the Lower Rio Grande Valley of Texas and Mexico**, F. F. BIBBY and I. MORENO. (U. S. D. A. coop. Tex. Expt. Sta. et al.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 736-737).—The secondary hosts of the pink bollworm in the Lower Rio Grande Valley here noted are okra, which ranks second to cotton in importance: *Malvaviscus drummondii*, found in many places in the Lower Rio Grande Valley, in a portion of Florida, along the entire Gulf Coast between Florida and Texas, and along the Atlantic Coast between Florida and Pamlico Sound, N. C., which is occasionally infested; and *Pseudobutylon locani*, a mallow found in nine counties of Texas and in Mexico, from which two pink bollworm moths emerged.

**The relation of moisture content of the cotton plant to oviposition by *Heliothis armigera* (Hbn.) and to survival of young larvae**, R. K. FLETCHER, (Tex. Expt. Sta. coop. U. S. D. A.). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 856-858).—An examination of the data obtained during the years 1935, 1936, and 1937 and again in 1938 and 1939 has shown that the correlation between the average percentage of moisture in the entire cotton plant and number of eggs per 100 plants was not significant. The correlation between oviposition and the percentage of water occurring in the growing tips only was found to be not significant in 1938 but was significant in 1939. In 1939 there was found to be a highly significant correlation between the number of larvae at each point and the percentage of moisture in the growing tips based on the weight of water in the entire plant. This highly significant correlation occurs even though it has often been found that a high percentage of the first-instar larvae is destroyed by predators.

**Guerra al gusano rosado de algodón**, G. N. WOLCOTT (*Agr. Expt. [Puerto Rico Univ. Sta.],* 1 (1941), No. 5, pp. [7-8], figs. 4).—A practical account of the fight against the pink bollworm.

**Preliminary report on Iowa mosquitoes**, J. A. ROWE. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 16 (1942), No. 2, pp. 211-225).—This report includes records of distribution and seasonal occurrence, notes on larval habitats, and larval associations. Thirty-five species, representing the genera *Anopheles*, *Uranotaenia*, *Theobaldia*, *Mansonella*, *Psorophora*, *Aedes*, and *Culex*, are recognized as occurring in the State.

**Notes on disease-carrying mosquitoes of North Dakota**, H. S. TELFORD and C. WESTER (*North Dakota Sta. Bimo. Bul.*, 4 (1941), No. 2, p. 13).—This records the discovery of *Anopheles maculipennis* and *A. punctipennis* in eastern North Dakota during the fall of 1941.

**Observations on mosquito transmission of *Plasmodium lophurae***, R. L. LAIRD (*Amer. Jour. Hyg.*, 34 (1941), No. 3, Sect. C, pp. 163-167).—Three mos-

quitoes, *Culex restuans*, *Aedes atropalpus*, and *A. albopictus*, were found to be susceptible to *P. lophurae*. Attempt to infect the yellow-fever mosquito and the northern house mosquito failed. Transmission of *P. lophurae* through *A. albopictus* was demonstrated. The presence of apparently mature sporozoites in the salivary glands of the mosquito host does not always indicate ability to infect a susceptible animal. Ducks recovered from an infection of *P. lophurae* were shown to have an immunity to superinfection with the same parasite.

The fruitflies of the genus *Anastrepha*, A. STONE (*U. S. Dept. Agr., Misc. Pub.* 439 (1942), pp. 112, pls. 23, figs. 22).—This publication discusses the economic importance, food plants, geographical distribution, and specific characters and terminology of members of the genus *Anastrepha*. A key is included for separation of the females. Besides the 104 old names, 52 new ones are proposed. The species incorrectly placed in the genus are mentioned, and those considered valid are described. Both photographs and figures are used to illustrate characters of different species. Ten references are cited, and an index to the various species is included.

Total carbohydrate and glycogen content of the developing honeybee, R. M. MELAMPY and R. D. OLSAN. (*U. S. D. A. and La. State Univ.*) (*Soc. Expt. Biol. and Med. Proc.*, 45 (1940), No. 2, pp. 754-758).—An investigation of the changes in the concentration of the total carbohydrate, glycogen, and free reducing sugar which occur in the development of the worker honeybee has shown that during the larval period there is a marked increase in the total carbohydrate and glycogen. During the pupal period both the total carbohydrate and glycogen decrease. At the time of emergence a very small amount of carbohydrate reserve remains. In addition to glycogen, there is in the tissues of the immature honeybee a reserve carbohydrate which is convertible, by acid hydrolysis, to reducing sugar. Free reducing sugar is found in the tissues of larval and pupal honeybees.

A revision of the chalcid-flies of the genus *Monodontomerus* in the United States National Museum, A. B. GAHAN (*U. S. Natl. Mus. Proc.*, 90 (1941), No. 3116, pp. 461-482).—Fifteen species of chalcid flies of the genus *Monodontomerus* at hand are described and hosts and their known occurrence recorded. Nine are new to science, of which seven are from the United States and two from Mexico.

Relapsing fever: *Ornithodoros parkeri* a vector in California, G. E. DAVIS, H. L. WYNNS, and M. D. BECK (*Pub. Health Rpts. [U. S.]*, 56 (1941), No. 51, pp. 2426-2428).—The first case of relapsing fever transmitted by the tick *O. parkeri* is recorded from Stanislaus County, Calif.

The citrus bud mite *Eriophyes sheldoni* Fwing, A. M. BOYCE and R. B. KOSMEIER. (*Calif. Citrus Expt. Sta.*). (*Jour. Econ. Ent.*, 34 (1941), No. 6, pp. 745-756, figs. 9).—This contribution (*E. S. R.*, 79, p. 663) reports upon the life history and habits, economic importance, and means of control of *E. sheldoni*, which was first recognized on lemon trees in Ventura County, Calif., in 1937 and has become a serious pest of lemons in that State. This mite has been found in five counties in the southern portion of California and is also recorded from Queensland and New South Wales in Australia and from the island of Oahu, Hawaii. *Citrus* species are the only known hosts. Nursery stock is probably the best medium for disseminating the mite into uninfected areas. In California the lemon is the only host in fruiting that is seriously affected. Approximately 25,000 acres of lemons are infested although the injury is only important on about 20,000 acres, most of which are in the coastal and intermediate areas. Owing to the very small size of this mite, the quantitative evaluation of the effectiveness of treatments for control is difficult. Fumigation

with HCN and also with vaporized nicotine under tented trees was not satisfactory. The regular petroleum oil that is used on citrus and sulfur or sulfur-containing materials applied as sprays have shown the greatest effectiveness of the various materials tested.

**The chigger and its control in Missouri.** P. C. STONE and L. HASEMAN (*Missouri Sta. Cir. 214 (1941), pp. [4], figs. 2).*—A practical account.

## ANIMAL PRODUCTION

[Experiments in livestock production by the Bureau of Animal Industry]. (Partly coop. expt. stas. et al.). (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt., 1941, pp. 4-5, 12-13, 14-17, 18, 21, 22-25, 27-28, 28-29, 30-31, 33-35, 40-43).*—Progress is presented on investigations of type in swine and amount and quality of feed and effect of sex on pork and beef production; tenderness of beef heated before freezing and storage; feed, mineral, and vitamin requirements for beef production; rat tests of the nutritive values of redtop, Kentucky bluegrass, and orchard grass; nutritive values of fats and oils for rats; feeds for quail; indexes for meat carcass quality; index of juiciness of meat; standards for grading and composition of pork and lamb carcasses and fat distribution on different rations; method of determination of salt and moisture in cured ham; mineral and vitamin A needs of beef cows; crested wheatgrass and western wheatgrass and lespedeza as sources of hay and pasture for yearling cattle; sweetpotato meal v. shelled corn; relation of efficiency of feed utilization to grade of steers; comparison of ryegrass pasture v. corn silage as roughage for steers; finishing yearling steers on lespedeza with and without white shelled corn; effect of intensity of grazing by beef cows and steers on range vegetation; calf production and gains in steers; fertilization and management of pastures and cottonseed cake for steers; relation of milking ability of ewes to lamb and mutton production; methods of measuring fiber fineness and variability and density of fiber in wool; comparisons of different rations for feeding sheep on pasture, range, and hay; relation of diet to milk production and fleshing in milk goats; feeding soybean meal and peanut meal in comparison with trinity mixture as supplements to corn for swine; nerve degeneration and incoordination in swine prevented by liver extract and vitamin B complex; electric hovers for pigs; feeding and measurements of production by horses; the prevention of poultry troubles (toe picking and cannibalism) by corrected nutrition; causes of gizzard erosion; absorption of fats; antirachitogenic nature of cereals for poultry; relation of wheat-germ oil and thyroid to semen production; fattening of turkeys; water consumption by poultry; and accomplishments of the National Poultry Improvement Plan during the first 6 yr.

[Animal production studies by the Alabama Station] (*Alabama Sta. Rpt. 1940, pp. 27-29).*—Studies are reported by W. D. Salmon, D. F. King, and G. J. Cottier on oat pasture as a protein supplement and basic slag as a mineral supplement for hogs, management of farm poultry flocks, the value of kudzu and other forms of summer green feed for poultry, and a comparison of kudzu meal and *Lespedeza sericea* leaf meal as vitamin supplements to the chick and laying rations.

[Investigations in livestock production by the Colorado Station] (*Colorado Sta. Rpt. 1941, pp. 20-21, 22, 35, 38-40).*—Results are briefly reported on studies of mineral composition of alfalfa hay, mineralized drinking waters for livestock, Middle Park hay and North Park hay for cattle, satisfactory use of iodine supplementation for ewes, iodine requirements of poultry, green feed for chickens and turkeys, and vitamin D and reproduction in turkeys.

**Records of performance for meat animals.** L. M. WINTERS. (*Minn. Expt. Sta.*). (*Empire Jour. Expt. Agr., 8 (1940), No. 32, pp. 259-268).*—The essential

factors to be considered in establishing records of performance for beef cattle, sheep, and swine are discussed. The desirability of individual feeding for knowing how efficiently meat is produced is of special interest.

**pH values of the contents of the gastro-intestinal tracts of some farm animals, O. E. OLSON.** (S. Dak. Expt. Sta.). (*S. Dak. Acad. Sci. Proc.*, 20 (1940), pp. 34-41).—The four stomachs of slaughtered sheep and cattle were similar in pH, while the pH of the hog's stomach was similar to that of the abomasum of sheep and cattle. The intestinal contents of the hogs and sheep ranged from neutral to slightly acid.

**The influence of plane of nutrition and of environmental temperature on the relationship between basal metabolism and endogenous nitrogen metabolism subsequently determined, R. TREICHLER and H. H. MITCHELL.** (Univ. Ill.). (*Jour. Nutr.*, 22 (1941), No. 4, pp. 333-343).—In studies of the effects of differences of plane of nutrition and environmental temperatures on the metabolism of rats it was found that the basal metabolic rate and the higher plane of nutrition, which permitted a slow gain at 28° C., was 8.3 percent higher than for rats on a maintenance ration. The endogenous nitrogen output in the urine per square meter of body surface averaged about 4 percent less on the higher plane of nutrition. The ratio of endogenous nitrogen to basal calories was considerably and significantly depressed by the higher caloric intake. In a second experiment in which the effects of temperatures of 4° and 28° were compared, as well as the excess and maintenance rations, it was found that the basal metabolic rate was significantly increased by prior exposure to the lower environmental temperature, as well as the effects of increased food. However, there were no significant differences in the basal metabolic rate at 4° and 28° if food intake was similar.

**Body size and metabolism of liver slices in vitro, M. KLEIBER.** (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 2, pp. 419-423, fig. 1).—The metabolic rate per unit of live weight in vitro of liver slices from rats, rabbits, sheep, one horse, and one cow was inversely proportional to the fourth root of body weight. Thus the metabolic rate of the intact animal and the factors which determine the metabolic level in vivo seem still to be present in surviving tissues from the organism, as noted previously (E. S. R., 66, p. 856). The oxygen consumption of liver slices cut from the living animal was measured in a respiration apparatus within from 15 to 30 min. after death.

**Metabolism trials with New Zealand feeding-stuffs, I, II, A. F. R. ADAMS and H. B. GARBETT** (*New Zeal. Jour. Sci. and Technol.*, 22 (1940), Nos. 3A, pp. 146A-151A; 4A, pp. 221.1-228A).—Two trials are presented.

I. *Rye-grass straw*.—In starch equivalents, ryegrass straw was found in feeding trials with three wethers to average 32.5 on a wet basis, which was intermediate between very poor and good hay. Mineral balances were positive for magnesium, potassium, and sodium but negative for chloride, phosphate, and lime on the submaintenance rations.

II. *Rape*.—On low and high intake levels with three wethers the starch values of rape were determined as 79 and 77, respectively, on a dry basis. Mineral balances showed rape to be high in calcium and satisfactory in phosphate and magnesium.

**New developments in making and feeding grass silage, M. H. BERRY.** (Md. Expt. Sta.). (*Md. Agr. Soc., Farm Bur., Rpt.*, 25 (1940), pp. 187-203).—A review is given of the molasses, phosphoric acid, A. I. V., and partial drying methods of making grass silage and of its nutritive value.

**The cystine and methionine in certain species of grassland herbage, A. M. SMITH and T. WANG** (*Biochem. Jour.*, 35 (1941), No. 3, pp. 404-412).—Samples

of white clover, orchardgrass (cocksfoot), perennial ryegrass, and timothy cut at different stages of growth and taken from different locations did not reveal significant differences in their contents of cystine and methionine, all being approximately 1.3 percent. Neither site nor manuring, with the exception of late nitrogen dressing, seemed to influence the results. The amounts of cystine and methionine rose to maxima when the plants reached or passed the heading stage, with smaller amounts thereafter.

**The pantothenic acid content of royal jelly,** P. B. PEARSON and C. J. BURGIN. (Tex. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 2, pp. 415-417).—Royal jelly was richer than any other known source of pantothenic acid. Assays of several samples showed royal jelly to contain an average of 183  $\mu$ g. of pantothenic acid per gram on a fresh basis and 511  $\mu$ g. on a dry-matter basis, which is from 2.5 to 6 times as much as is found in yeast or liver.

**The minimum requirement of rabbits for dl- $\alpha$ -tocopherol,** S. H. EPPSTEIN and S. MOREULIS. (Univ. Nebr.). (*Jour. Nutr.*, 22 (1941), No. 4, pp. 415-424, figs. 2).—Comparisons of the effects of different doses of  $\alpha$ -tocopherol in the treatment and prevention of muscular dystrophy in rabbits indicated that the minimum requirement was probably about 0.32 mg. per kilogram of body weight per day. There was a direct relation between the total amount of  $\alpha$ -tocopherol fed and the time interval over which it cured and protected the animal when the amount was less than about 60 mg. Sex and age did not affect the vitamin E requirement.

**Some practical aspects of present vitamin knowledge for the farmer,** P. E. JOHNSON (*North Dakota Sta. Bimo. Bul.*, 4 (1941), No. 2, pp. 14-18).—A review is given of the vitamins needed and their sources in livestock rations.

**Inspection of commercial feeding stuffs,** H. R. KRAYBILL ET AL. (*Indiana Sta. Cir.* 266 (1941), pp. 58, fig. 1).—A summary is given of the analyses of feeds officially inspected during 1940 (E. S. R., 84, p. 228), together with information on the Indiana feeding stuffs law and feeds for specific purposes.

**Commercial feeding stuffs, 1940-41,** E. R. TOBEY (*Maine Sta. Off. Insp.* 180 (1941), pp. 62).—The guaranteed and found analyses of the 807 samples of feedstuffs officially examined in 1940-41 are classified according to types of feed (E. S. R., 84, p. 798).

**Inspection of commercial feeding stuffs, 1941,** T. O. SMITH and H. A. DAVIS (*New Hampshire Sta. Bul.* 333 (1941), pp. 56).—The usual report of the guaranteed and found analyses of 466 brands of feeds officially examined during the year ended June 1941 (E. S. R., 84, p. 656).

**Utilization of home grown feeds in fattening steers in the trans-Pecos region,** J. H. and J. M. JONES and J. J. BAYLES. (Coop. U. S. D. A.). (*Texas Sta. Bul.* 604 (1941), pp. 51, figs. 21).—In 8 years' experiments, comparisons of rations containing moderately large amounts of concentrates with other rations containing large amounts of roughage for yearling Hereford steers showed that rations high in roughage may produce reasonably well-finished steers when fed for about 200 days. The rations fed included ground threshed milo, ground milo heads, cottonseed, cottonseed meal, ground hegari fodder, alfalfa hay, hegari silage, oystershell, and salt. High gains were secured without addition of milo before 112 or 140 days. Only small amounts of alfalfa hay proved advantageous in rations high in ground hegari fodder, and ground hegari fodder proved more desirable than alfalfa hay as the sole roughage in high-concentrate rations. Self-feeding proved an entirely satisfactory method for feeding rations high in ground hegari fodder. Amounts of cottonseed replacing one-third of the ground milo grain in full-fed concentrate rations supplemented with cottonseed meal or in rations high in roughage feeds improved gain and

finish. Cottonseed proved a more satisfactory supplement to milo and cottonseed meal than as a replacement for either. Better results were obtained with the three feeds than with any two. No benefit resulted from feeding oystershell when hegari fodder was the sole roughage.

**Soybean and Korean lespedeza hays compared with alfalfa for wintering beef calves.** E. W. McCOMAS, M. W. HAZEN, and J. E. COMFORT. (Coop. Univ. Mo.). (*U. S. Dept. Agr. Cir. 629* (1942), pp. 8).—Although the commercial grades of hay varied and the gains of cattle differed, soybean, lespedeza, and alfalfa hay gave satisfactory results for fattening calves with corn, cottonseed meal, and sorgo silage in two 1-yr. experiments of 140 days each. At the start of the first experiment the calves averaged 360 lb., but the animals used in the second year started at from 315 to 325 lb. In the first experiment the average daily gains were about 1.5 lb., but in the second test, which was conducted on a slightly higher nutritive plane, they reached about 2 lb.

**Feeding value of rice by-products.** M. G. SNELL (La. Expt. Sta.) (*Rice News*, 9 (1941), No. 1, p. 16).—In a 112-day finishing period with approximately 500-lb. steers, a mixture of rice polish and rice bran proved to have 82 percent of the feeding value of ground corn when fed with cottonseed meal and rice straw. Blackstrap molasses mixed with rice bran and rice polish had about 80-90 percent of the feeding value of corn. The average daily gain produced on the standard ration of 2.78 lb. was reduced to 2.3 to 2.5 lb. when the corn was replaced by the rice products alone or with the molasses.

**Canadian Wiltshire bacon, XX-XXII** (*Canad. Jour. Res.*, 19 (1941), Sect. D, Nos. 7, pp. 213-224, fig. 1; 8, pp. 225-232, fig. 1; pp. 233-239).—Three papers in continuation of this series (E. S. R., 86, p. 367) are as follows:

**XX. A comparison of certain chemical and physical properties of Canadian and Danish bacons, and their relation to flavour quality.** W. H. White, C. A. Winkler, and W. H. Cook.—A variance analysis of the physical and chemical properties of 9 samples of Wiltshire sides from each of 18 Canadian and 10 Danish factories showed that Canadian bacon generally contained more salt and was slightly drier and tougher than the Danish product. The greatest variation in the Canadian bacon was due to differences in factories, but differences between sides were the principal sources of variation in Danish bacon. Improvement in the flavor quality of Canadian Wiltshire bacon could be achieved by milder cures and improved handling and curing practices.

**XXI. Objective colour comparisons of Canadian and Danish bacons, and their relation to subjective observations of colour quality.** C. A. Winkler, G. Abel, and W. H. Cook.—Analyses of the color determinations of samples of Danish and Canadian bacon showed Danish bacon to be lighter in color than Canadian bacon in the smoked and unsmoked conditions, but the color was equally stable in bacon from both sources. Comparison of photoelectric determinations of the scatter in terms of specific colors with subjective estimates of color by the six members of the jury indicated colors of bacon of satisfactory quality.

**XXII. Comparative carcass quality of Canadian and Danish bacons.** C. A. Winkler, W. H. White, and G. Abel.—Study of samples of Canadian and Danish Wiltshire showed that, although the carcasses were essentially the same, the eye of lean of the Canadian bacon was slightly longer than, but approximately equal in width to, that of the Danish bacon. Canadian factories were definitely superior regarding the precaution to prevent scorching during singeing.

**A check list of poultry bulletins (1931-1940).** L. E. CARD. (Univ. Ill.). (*Poultry Sci.*, 21 (1942), No. 1, pp. 58-69).—A compilation is given of the research

and technical bulletins relating to poultry and eggs which have been issued by the experiment stations from 1931 to 1940, inclusive.

**Avoiding failure in the poultry business**, W. C. THOMPSON (*New Jersey Stas. Hints to Poultrymen*, 28 (1941), No. 6, pp. [4]).—Advice on poultry production as a business enterprise is presented.

**Removing gizzard contents from living birds**, E. S. MCCONNELL (Univ. Ga.). (*Poultry Sci.*, 21 (1942), No. 1, pp. 45-46, figs. 2).—Description is given of a method and apparatus which were successful for removing the gizzard contents from 90 percent of the living birds tested.

**Satisfactory poultry rations for Maryland conditions**, H. R. BIRD. (Univ. Md.). (*Md. Agr. Soc., Farm Bur., Rpt.*, 25 (1940), pp. 299-300).—Rations are recommended for starting, growing, and laying mashers.

**Cafeteria feeding of Leghorn pullets**, C. S. PLATT and V. DARAGO (*New Jersey Stas. Hints to Poultrymen*, 29 (1941), No. 1, pp. [4]).—The egg production rate of White Leghorn pullets fed free choice on corn, oats, and mash from 12 weeks of age through the first year of egg production was approximately 54 percent for 1939 and 1940. Mortality in the respective years was 20.8 and 16.8 percent.

**The accumulation of protein in the oviduct of the fowl**, R. M. CONRAD and H. M. SCOTT. (Kans. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 1, pp. 81-85, fig. 1).—Oviducts removed from hens at various times in the egg production cycle showed that soluble protein accumulates in the magnum at the rate of 4.05 percent per hour of the amount found in the fully formed egg, even with a pause between clutches. Histological studies showed the stage of activity of the tubular glands underlying the epithelium to influence the depth of the ciliated and mucous-secreting cells lining the lumen of the duct. There was no evidence of a storage of mucin.

**Utilization of urea nitrogen by growing chicks**, C. M. BICE and L. A. DEAN. (Hawaii Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 1, pp. 15-17).—Growth of chicks on rations in which urea replaced one-third, two-thirds, and all of the protein supplement up to 16 weeks of age showed that the chicks did not utilize the urea. Similar results were obtained when raw sugar as a source of readily soluble carbohydrate was included in the ration of two other lots. Growth up to 12 weeks on rations in which the meat scrap, fish meal, linseed meal, and soybean meal were replaced by urea was only slightly greater than on rations without urea in which these protein feeds were low.

**"Leg-weakness" in laying hens on an ascorbic acid-free (vitamin C) diet**, T. A. BELL, G. H. SATTERFIELD, and F. W. COOK. (Univ. N. C.). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 2, pp. 473-475).—Certain hens, under the demands of heavy egg production and on a diet deficient in vitamin C, developed avitaminosis C resulting in leg weakness, inanition, and a depression of egg production. The mash and grain of 15 Barred Plymouth Rock hens fed in batteries were devoid of vitamin C, but by injections of 100 mg. of ascorbic acid every second day symptoms of vitamin C deficiency and leg weakness were prevented. Three of the hens not receiving the C supplement developed leg weakness and stopped laying after 62, 67, and 68 days, respectively, on the diet. Dramatic recovery was produced and egg production was renewed by 10 daily injections of 1,000 mg. of ascorbic acid. The need for vitamin C by high-producing birds seems apparent.

**Tryptophane requirement of the chick**, H. J. ALMQUIST and E. MECCHI. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 2, pp. 526-528).—Additions of from 0.16 to 0.36 percent of L-tryptophan to a ration did not increase the growth rate as determined at frequent intervals for from 6 to 9 days. A

diet of 0.44 percent *l*-tryptophan seemed sufficient for a good rate of growth. In other experiments in which the casein was hydrolyzed the chicks lost weight, but when increased amounts of *l*-tryptophan were added the rate of gain increased. The optimum growth was attained with approximately 0.5 percent of *l*-tryptophan in the ration.

**Relation of a growth factor required by *Lactobacillus casei* to the nutrition of the chick**, B. L. HUTCHINGS, N. BOHONOS, D. M. HEGSTED, C. A. ELVEHJEM, and W. H. PETERSON. (Univ. Wis.). (*Jour. Biol. Chem.*, 140 (1941), No. 2, pp. 681-682).—Additions of a concentrate of the factor required by *L. casei* (= *L. helveticus*) (E. S. R., 83, p. 460) to a complete ration for chicks were found to increase the weights the chicks attained at 4 weeks of age from an average of 106 gm. with no additional supplement to 192 gm. with the concentrate. A purified concentrate from this one produced chicks weighing only 124 gm. at 4 weeks. In storage, approximately the same amount of activity for both the bacterial and chick factors was lost. It appears that the chick and bacterial factors are identical.

**Mineral partition during intestinal digestion of normal- and high-mineral rations by chicks**, S. L. BANDEMER and P. J. SCHAIBLE. (Mich. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 1, pp. 3-7, fig. 1).—Oystershell and bonemeal remained undissolved in calcium and phosphorus solutions in vitro at acid reactions similar to those found in the small intestine, and, as a solid phase, calcium was removed partially, and phosphorus more completely, from solution. Changes in the contents of the first, second, and third portions of the intestine of baby chicks after 5 weeks' feeding in groups on a basal ration or with additions of 7 percent of oystershell or bonemeal showed that on the normal ration the insoluble calcium and phosphorus increased and water decreased as the intestine was traversed. With high-mineral rations the soluble calcium concentration was greater than normal in the first portion of the small intestine, but lower in the intestine the amount of soluble minerals decreased and the insoluble form increased. Neither calcium nor phosphorus per se seemed to be responsible for perosis, since bonemeal produced more perosis but did not alter the blood and bone composition; whereas oystershell caused high blood calcium, low blood phosphorus, and low bone ash.

**Environmental temperature and infertility in White Leghorns**, W. F. LAMOREUX. (Cornell Univ.). (*Poultry Sci.*, 21 (1942), No. 1, pp. 18-22).—Analysis by variance of the percentage of fertility of 7 different hatches totaling over 20,000 eggs laid by 593 White Leghorn hens mated with 71 ♂s in uninsulated breeding pens from 1935 to 1940 showed that there were significant differences between years which could not be accounted for by temperature differences. As partial explanation of discordance with the results of Hays and Sanborn (E. S. R., 81, p. 636), it is pointed out that the data in this study were based on eggs laid by hens under artificial lighting and that most of the ♂s were dubbed.

**Hatching ability of poultry.—I, Texture of egg shells in relation to loss of weight during incubation**, E. W. HENDERSON (*Michigan Sta. Quart. Bul.*, 24 (1941), No. 2, pp. 118-122, pl. 1, fig. 1).—The percentage of moisture lost in eggs during incubation was associated with candling score, ranging from 10.47 to 12.91 for 2,300 eggs. There was no correlation of microscopic pores to candling texture.

**Differences between high and low quality fresh eggs**, R. M. CONRAD and H. M. SCOTT. (Kans. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 1, pp. 77-80).—From a study of the composition and chemical properties of the eggs of 24 hens laying the highest-quality and 26 hens laying the lowest-quality eggs from a flock of 450 Rhode Island Red and White Leghorn hens, the only factor that

showed a significant relation to quality was the sodium concentration in the white, although potassium was suggestive of significance. There was no significant relation of the quality of the fresh egg to calcium, magnesium, or mucin content of the white or histological structure of the oviduct of the hens laying these eggs. Evidently something other than these factors has a great influence in determining the quality of the freshly laid egg.

**Fifty years of refrigeration in the egg and poultry industry**, M. E. PENNINGTON (*Ice and Refrig.*, 101 (1941), No. 1, pp. 45-48).—A review is given of progress in preservation of poultry meat and eggs through refrigeration.

**Feeding and confinement rearing experiment with turkeys during 1940**, F. N. BARRETT, C. G. CARD, and A. BERRIDGE (*Mich. Sta. Quart. Bul.*, 24 (1941), No. 2, pp. 101-110).—Continuing previous studies on management and feeding of turkeys (E. S. R., 84, p. 661), the authors found that the total amount of grain consumed per unit of gain and the proportion of grain to mash were consistently increased by free-choice feeding of corn and oats, as compared with feeding corn alone. When corn, wheat, oats, and barley were fed free-choice as the grain, oats continued to exceed the combined total consumption of the other grains. Corn was not heavily consumed until about the nineteenth week of age. A cobblestone yard proved very successful for rearing turkeys in confinement. The 1940 trials were conducted with 10 lots each having 30 standard or small-type Bronze turkeys or reciprocal crosses between them.

**Biotin and prevention of dermatitis in turkey poults**, H. PATRICK, R. V. BOUCHER, R. A. DUTCHER, and H. C. KNANDL. (Pa. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 2, pp. 456-458).—Dermatitis occurred by 4 weeks of age in a large number of the turkey poults on rations containing riboflavin, pantothenic acid, nicotinic acid, cane molasses, water- and alcohol-soluble fractions of dried beef liver, and dried brewers' yeast. However, residues from liver and yeast extraction rendered complete protection. These results suggested the presence of biotin, and it was found that a biotin concentrate free of other members of the B complex gave complete protection from dermatitis although growth was slow. Dermatitis occurred in 89 percent of the poults on the ration without biotin. When the basal ration was fed plus 5 percent of yeast residue and 0.0005 percent of riboflavin, rapid growth was attained.

**New device simplifies breeder selection**, W. E. POLEY. (S. Dak. State Col.). (*Turkey World*, 16 (1941), No. 9, pp. 12-13, 43-47, figs. 5).—A review is given of methods developed from measurements previously noted by Milby et al. (E. S. R., 81, p. 95) for selection of turkeys as breeders.

## DAIRY FARMING—DAIRYING

**A double change-over design for dairy cattle feeding experiments**, W. G. COCHRAN, K. M. AUTREY, and C. Y. CANNON. (Iowa Expt. Sta.). (*Jour. Dairy Sci.*, 24 (1941), No. 11, pp. 937-951).—The design of a short-time switch-over trial, comparing 3 rations, and the procedure for the statistical analysis of the data are described. The principal feature of the design is the division of the experimental animals (18 in this case) into groups of 3 on the basis of expected yielding ability. The 3 sequences of feeding are then allotted at random to the 3 cows of each group. Thus each group of 3 cows constitutes an independent experiment of the 3 x 3 Latin-square type. The principal objects of the design are to secure accurate comparisons of the effect of the rations and unbiased estimates of the experimental errors. It is also possible by this method to estimate and adjust for carry-over effects, which usually have been ignored in switch-over trials. A corresponding design for 4 rations is briefly described.

**Careful handling of beet tops will enhance value as additional roughage for dairy cows.** H. C. DICKEY (*Colo. Farm Bul. [Colorado Sta.]*, 3 (1941), No. 4, pp. 12-13).—It is recommended that clean beet tops be ensiled either in silos or in stacks, but that dirty or muddy tops be dried in small piles in the field. The addition of 1 oz. of ground limestone to each 50 lb. of beet tops at the time of feeding improved their feeding value for dairy cows, probably because of the neutralization of the oxalic acid in the beet tops. The limited feeding of beet tops supplemented with hay and grain is preferred to unlimited feeding of the tops.

**Straw pulp: Results of controlled feeding trials** (*Agriculture, Jour. Min. Agr. [Gt. Brit.]*, 48 (1941), No. 2, pp. 85-91).—This report presents the results of controlled feeding trials with cattle at five research centers in England and Wales to determine the nutritive value of chopped cereal straw (wheat and barley) treated with caustic soda. This treatment, commonly known as the "straw pulp process," consists of soaking the chopped straw in a 1.5-percent solution of caustic soda for 20 hr., draining, and then washing with water for about 4 hr. The results reported are somewhat variable. In trials at the National Institute for Research in Dairying and the Hertfordshire Institute of Agriculture with growing dairy heifers, the treated straw when fed as the supplement to a suitably balanced ration was significantly better than the untreated straw in promoting growth. A steer fattening trial at the Midland Agricultural College, in which treated and untreated straws were fed as supplements to a basic ration of hay, concentrate mixture, and minerals, showed an advantage of 0.7 lb. daily gain per head for the group receiving the straw pulp. On the other hand, steer fattening tests at Cambridge University and the Norfolk Agricultural Station showed no significant advantage of the treated straw over untreated straw as supplements to a fattening ration.

**From minerals to vitamins: The story of a change in emphasis in cattle feeding.** V. R. GARDNER (*Michigan Sta. Quart. Bul.*, 24 (1941), No. 2, pp. 95-98).—This is a brief résumé of research in this field at the station, with particular emphasis on the minimum carotene requirements of cattle, which are placed at about 50 mg. daily per 1,000 lb. live weight. The necessity of providing an ample supply of high-quality roughage to meet these requirements and to provide a substantial proportion of the total nutrient intake is stressed.

**The vitamin A content of milk and storage tissues of dairy cows as related to pasture and feeding practices.** C. J. KOEHN (*Alabama Sta. Rpt.* 1940, pp. 25-27).—Included are brief progress reports of studies on seasonal variation in the vitamin A content of milk, the effect of winter pasture on the vitamin A content of milk, and the carotene content of various dairy feeds.

**Physiology of dairy cattle, II** (*Jour. Dairy Res. [London]*, 12 (1941), No. 2, pp. 213-226).—Continuing this biennial review series (*E. S. R.*, 81, p. 412), part 2, Nutrition, by E. C. OWEN, gives a comprehensive review of recent developments within this field, with 153 references to the literature.

**The relation between the fat and carbohydrate metabolism of lactation, as indicated by the respiratory quotient of the mammary gland.** E. P. REINEKE, W. D. STONEOPHER, and C. W. TURNER. (*Mo. Expt. Sta.*). (*Amer. Jour. Physiol.*, 132 (1941), No. 2, pp. 535-541).—Respiratory quotients of the mammary gland of goats, calculated on the basis of the oxygen and carbon dioxide contents in simultaneously drawn arterial and mammary venous bloods, were found to be as follows: Lactating gland (blood samples drawn with no preliminary anesthesia)  $1.17 \pm 0.0361$ , lactating gland (blood samples drawn with blood vessels anesthetized locally)  $1.15 \pm 0.034$ , lactating gland (blood samples drawn while the animals were under mild nembutal anesthesia)  $1.09 \pm 0.0115$ , gland of

nonlactating pregnant goat 1.09, and gland of nonlactating, nonpregnant goat 0.81. When lactating goats were fasted the respiratory quotient of the mammary gland declined to below unity by the third day of fast. In view of the known declines in the lower fatty acids of milk fat during fasting, this parallel decline of the respiratory quotient with advance of fasting suggests that the synthesis of milk fat from carbohydrate is confined largely to the fatty acids of low molecular weight. The carbohydrate balance of the lactating mammary gland and its relationship to the possible synthesis of milk fat from carbohydrate is discussed (E. S. R., 86, p. 235).

**Suggestive evidence for the existence of a new factor essential for lactation, B. SURE.** (Univ. Ark.). (*Jour. Biol. Chem.*, 140 (1941), No. 1, p. CXXX).—A factor in addition to vitamins A, D, and K, thiamin, riboflavin, pyridoxin, calcium pantothenate, choline, and factor W was found necessary for lactating ♀ rats to rear their young. The missing substance was supplied by liver, rice bran, defatted wheat embryo, and brewers' yeast.

**Comparison of assay methods using International Standard lactogen, J. MEITES, A. J. BERGMAN, and C. W. TURNER.** (Mo. Expt. Sta.). (*Endocrinology*, 28 (1941), No. 5, pp. 707-709).—To induce a crop-gland response in 50 percent of 20 pigeons there were required 1, 1.25, and 0.00625 International Units of lactogen administered by the subcutaneous, intrapectoral, and intradermal (micro) method (E. S. R., 83, p. 328). Because of its sensitivity, the intradermal method was preferred for assaying blood, urine, and body tissues.

**Effect of estrogens, gonadotropins, and growth hormone on mammary glands of hypophysectomized rats, R. P. REECE and S. L. LEONARD.** (N. J. Expt. Stas.). (*Endocrinology*, 29 (1941), No. 3, pp. 297-305, figs. 14).—Oestrogen administered to castrated hypophysectomized, hypophysectomized ♂, and spayed hypophysectomized rats had no influence on mammary gland development. A negative influence was also noted from endogenous oestrogen produced by gonadotropic hormones. Growth hormone produced slight mammary growth, but the simultaneous administration of oestrogen stimulated growth of the duct system, perhaps by liberation of the mammogenic factor contained in the growth hormone.

**Effect of thyroidectomy of young male goats upon certain AP hormones, E. P. REINEKE, A. J. BERGMAN, and C. W. TURNER.** (Mo. Expt. Sta.). (*Endocrinology*, 29 (1941), No. 3, pp. 306-312).—Assays showed the pituitaries of eight ♂ kids thyroidectomized at from 5 to 24 days of age to contain normal amounts of lactogenic and thyrotropic hormones when the animals were killed at approximately 4 mo. of age. The gonadotropic hormone was present in the thyroidectomized kids only in amounts little more than half that found in normal kids, and the testes were 34 percent smaller than normal. In thyroidectomized animals the sugar-elevating factor of the pituitaries was very low, and the liver size was 20 percent less than normal.

**Relation of size of litter to AP lactogen content of nursing rabbits, J. MEITES, A. J. BERGMAN, and C. W. TURNER.** (Mo. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 46 (1941), No. 4, pp. 670-671).—The lactogen content of the anterior lobe of the pituitary was not related to the size of litter, as ascertained by the Reece-Turner method (E. S. R., 78, p. 323). There were no significant differences in the lactogen content of the pituitaries of 11 does permitted to nurse litters of from 5 to 11 young and 10 does whose litters were reduced to 2 at 5 days after birth.

**Thyrotropic hormone content of rabbit pituitary during growth, A. J. BERGMAN and C. W. TURNER.** (Mo. Expt. Sta.). (*Endocrinology*, 29 (1941), No. 3, pp. 313-319, figs. 4).—The amounts of thyrotropic hormone in each pituitary

and per gram of fresh tissue in ♂ and ♀ rabbits were increased with size to live weights of 2,500 gm., but a decline occurred for larger weights. The fact that the hormone in the pituitaries of the two sexes of the rabbit was similar, in contrast to other animals, was noted. The method of assaying the pituitaries for the thyrotropic hormone was with chicks, as previously noted (E. S. R., 82, p. 172).

**Assay of posterior pituitary factors which contract the lactating mammary gland,** C. W. TURNER and W. D. COOPER. (Mo. Expt. Sta.). (*Endocrinology*, 29 (1941), No. 3, pp. 320-323).—Determination was made of the factor present in the posterior lobe of the pituitary which caused a definite contraction of the mammary gland of an unnursed lactating rabbit within 40 sec. following intravenous injection. Comparative assays were given on commercial pituitrin, pitocin, and pitressin.

**Biological assay of the mammogenic lobule-alveolar growth factor of the anterior pituitary,** J. P. MIXNIE and C. W. TURNER. (Mo. Expt. Sta.). (*Endocrinology*, 29 (1941), No. 3, pp. 324-329, figs. 4).—A unit of mammogenic lobule-alveolar growth factor was defined as the amount of pituitary material injected subcutaneously over a 10-day period which caused lobule-alveolar development in  $50 \pm 10$  percent of 10 ovariectomized nulliparous mice. This result was tested by anterior pituitary material from catle and progesterone. A mouse unit of mammary growth factor was supplied by 875 $\gamma$  of progesterone injected with oestrone.

**A study of breeding records of one large herd of dairy cattle,** M. S. HORSTAD (*Cornell Vet.*, 31 (1941), No. 4, pp. 379-381).—A study of breeding records covering 309 conceptions indicated that the post partum sexual rest period averaged 94.5 days and the average number of services per conception was 1.65. Cows bred before the sixtieth day following calving required a higher average number of services per conception, and the percentage of abortions and cases of metritis, dystocias, and retained placentas among this group was relatively high. It is concluded from these data that breeding before the sixtieth day following parturition should be discouraged and that the best interval of rest between calving and the first breeding is from 90 to 100 days.

[Abstracts of dissertations on dairy problems] (In *Cornell University Abstracts of Theses*, 1940. Ithaca, N. Y.: Cornell Univ. Press, 1941, pp. 270-271, 352-357, 415-416, 422-426).—Abstracts of the following doctoral theses pertaining to dairy problems are given: The Chemical Changes Occurring in Phosphoric Acid Silage, by E. J. E. Pagé (pp. 270-271); A Study of *Lactobacillus casei* and Related Organisms, by F. J. Rudert (pp. 352-354); Gas Production and Biochemical Properties on *Proteus* Bacteria, by M. L. Speck (pp. 355-357); Yeast in Concentrate Mixtures for Dairy Calves, by K. E. Gardner (pp. 415-416); Comparison of Dried Beet Pulp Versus Freshly Chopped Mangel Beets for Milk and Fat Production, by L. K. H. Lu (pp. 422-423); and The Effect of the Time and Temperature of Pasteurization Upon Some of the Properties and Constituents of Milk, by R. F. Holland (pp. 424-426).

**Vitamin A and C in cow's milk, with a note on the synthesis of vitamin C in bovines,** S. N. RAY, KARAM CHAND, and K. GOVIND RAU (*Jour. Dairy Res.* [London], 12 (1941), No. 2, pp. 109-118).—In studies at the Imperial Veterinary Research Institute, India, the method of Olson et al (E. S. R., 81, p. 269) for carotene and vitamin A determination and the standard titration method for vitamin C determination were applied to the milk of representative cows. Average values obtained were carotene  $71 \pm 32.08$  yellow units per 100 cc., vitamin A  $115.6 \pm 35.46$  blue units per 100 cc., and ascorbic acid  $1.94 \pm 0.35$  mg. per 100 cc.

Protecting milk from light was found to be highly effective in preserving its vitamin C content.

To test the ability of cattle to synthesize vitamin C, young calves were maintained for long periods on a vitamin C-free diet. No significant variations occurred in the vitamin C concentration in the blood of the experimental and control groups, indicating that the calves were able to synthesize sufficient vitamin C for normal growth and activity. Attempts to produce vitamin C in vitro by growing bacteria isolated from various parts of the alimentary tract were unsuccessful.

**Studies on ass's milk: Composition,** C. P. ANANTAKRISHNAN (*Jour. Dairy Res. [London], 12 (1941), No. 2, pp. 119-130*).—This report from the Indian Institute of Science, Bangalore, indicates that the total solids of samples of ass's milk ranged from 7.8 to 9.1, the solids-not-fat from 7.14 to 8.5, and the fat from 0.54 to 0.71 percent. The milk was characterized by low casein, low globulin, and high albumin content, with average respective values of 0.7, 0.07, and 0.62 percent. Other average values were lactose 6.1, chloride 0.037, calcium 0.081, and phosphorus 0.059 percent. The fat had a relatively high iodine value and low Reichert and Krischner values.

**Stability of the fat emulsion of homogenized milk,** F. J. DOAN, D. V. JOSEPHSON, and J. ADAMS. (Pa. Expt. Sta.). (*Milk Dealer, 31 (1941), No. 2, pp. 35, 54, 56, 58-61, figs. 2*).—A study of 25 commercial lots (quarts) of homogenized milk held at from 40° to 43° F. for 48 hr. gave evidence that the difference between the fat content of the upper 100 cc. and the remainder of the total content varied from 2.5 to 77.0 percent, with only 8 of the samples meeting the U. S. Public Health Service definition of homogenized milk that "the fat percentage of the top 100 cc. of milk in a quart bottle, or of proportionate volumes in containers of other sizes, does not differ by more than 5 percent of itself from the fat percentage of the remaining milk as determined after thorough mixing."

Test with five piston-type homogenizers and one each of a rotary- and a centrifugal-type homogenizer gave evidence that the piston-type machine must be operated at pressures above 3,000 lb. to produce consistently milk meeting the U. S. Public Health Service specification, while the rotary and centrifugal machines used could not process milk to meet this definition. However, the rotary homogenizer was more efficient than the piston-type machine in stabilizing the fat emulsion in milk when similar pressures were employed. The fat content of homogenized milk within a range of from 3.5 to 4.5 per cent had only a very small and inconsistent effect on the stability of the fat emulsion. A modification of the Babcock test for homogenized milk is described. A comparison of the U. S. Public Health Service Index and the Farrall Index of efficiency of homogenization (E. S. R., 85, p. 520) indicated that a percentage difference of 5 under the former corresponds to a Farrall Index of about 20. It is the opinion of the author that the Public Health Service definition of homogenized milk is unreasonably stringent.

**The influence of the time and temperature of homogenization on certain properties of the milk,** G. M. TROUT and M. V. SCHMID (*Michigan Sta. Quart. Bul., 24 (1941), No. 2, pp. 122-131, pls. 2, fig. 1*).—A survey of the sequence of processing in 23 milk plants revealed that 4 homogenized before pasteurization, 5 homogenized after pasteurization with clarification, and 14 homogenized after pasteurization without clarification. Pasteurization temperatures ranged from 142° F. for 30 min. to 160° for 20 min., while homogenization pressures ranged between 2,000 and 3,000 lb. In experiments on the effect of homogenizing at various temperatures, raw milk previously held 24 hr. at 40° gave evidence that

at 5,000 lb. pressure complete dispersion of the fat did not occur at temperatures of 40°, 60°, or 80°, whereas dispersion was complete at 100°, 120°, or 140°. Marked acidity increases occurred when homogenization was carried out from 80° to 120°, but only slight increases occurred at 60° or 140° and none at 40°. Rehomo-genization of raw milk five times at 40° at 5,000 lb. pressure failed to disperse the fat, increase acidity, or alter flavor, even after 96 hours' storage. Pasteurization of milk homogenized raw at 100° prevented the development of rancidity but did not reduce the increase in acidity. It is stressed that when milk is homogenized before pasteurization facilities must be available for preheating milk to a desirable temperature for homogenization and for immediate subsequent heating to inactivate lipase, or preheating to a temperature which has practically inactivated the enzyme at the time of homogenization.

**Foaming of homogenized milk,** G. M. TROUT and M. V. SCHEID (*Michigan Sta. Quart. Bul.*, 24 (1941), No. 2, pp. 113-115).—Based on the percentage increase in volume resulting from whipping for 30 sec. one hour after pasteurizing and cooling, it was determined that raw milk homogenized at 100° F. and then pasteurized exhibited much less foaming than milk homogenized after pasteurization. Pasteurized milk homogenized at 143° foamed only slightly more than at 100°, the difference apparently having no commercial significance. It is the authors' opinion that foaming of homogenized milk may be overcome by correcting certain handling defects rather than by varying the temperature or sequence of homogenization.

**Flavor development in dairy products by microorganisms,** B. W. HAMMER (Iowa State Col.). (*Inst. Food Technol. Proc.*, 1 (1940), pp. 279-287).—A general discussion covering cultured buttermilk, salted and unsalted butter, and various types of cheese. The role of various chemical compounds responsible for flavors in dairy products is also briefly discussed.

**The lactate-fermenting anaerobic and facultative organisms in silage,** V. F. MARTOS. (Univ. Wis.). (*Jour. Bact.*, 42 (1941), No. 1, pp. 140-141).—Bacterial analyses of silage samples indicated that anaerobic, lactate-fermenting sporeformers may be present in large numbers up to 100,000 per gram during the fermentation process, but that they are reduced to very low numbers after a pH of about 4 is reached. However, facultative lactate-fermenting sporeformers belonging to the *Aerobacillus* group were consistently present in relatively large numbers even when the pH was as low as 4. The number of these organisms in the feces of cows receiving the silage was from 10 to 100 times higher than in the silage fed. The possibility of the aerobacilli present in silage becoming an important contaminant of milk for cheese making is suggested, since it was found that this group of organisms may inhibit acid production by *Streptococcus thermophilus* and *Lactobacillus bulgaricus*.

**Milk-borne diseases,** J. SMITH (*Jour. Dairy Res.* [London], 12 (1941), No. 2, pp. 227-240).—This contribution to the biennial review series (E. S. R., 82, p. 388) covers the recent literature on the more prevalent types of milk-borne diseases, with 71 reference citations.

**The relationship of methods of bacteriological examination to the eradication and control of mastitis (*Streptococcus agalactiae*), I, II,** A. T. R. MATTHEW, P. M. F. SHATTOCK, and M. MORRIS JACOB (*Jour. Dairy Res.* [London], 12 (1941), No. 2, pp. 139-154).—The results of two studies are reported.

**I. The use of an enrichment technique in revealing streptococcal infections of the cow's udder** (pp. 142-151).—A comparison of several bacteriological techniques for revealing the presence of *S. agalactiae* in milk indicated that the use of sodium azide broth gave about the same results as the Edwards plating method. By use of an enrichment method consisting of the incubation for 24 hr.

at 37° C. of 9.5 cc. of milk mixed with 0.5 cc. of an alcohol-water solution of bromo cresol purple (final concentration 0.025 percent), followed by heavy streaking on Edwards' esculin crystal violet blood agar plates, it was possible to show many cases of infection with small numbers of *S. agalactiae* which gave negative results by other methods. It was also shown that the frequency of examination may have an important bearing on the number of positive cases discovered. On the basis of six herd histories recorded, it was evident that light infections may persist for long periods. Light udder infections with *S. dysgalactiae* or *S. uberis* and also mixed infections of *S. agalactiae* and *S. dysgalactiae* were frequently revealed.

II. *Streptococcus agalactiae* infections in heifers (pp. 151-154).—Applications of the Edwards test on 377 heifers showed that 4.5 percent harbored *S. agalactiae* in their udders from 10 to 20 days before calving and while isolated from the milking herd. About 21 percent gave positive mastitis reactions during their first lactation period. The bearing of these findings on the theory of contagion in *S. agalactiae* infections is discussed.

The use of chlorine in the near-sterilisation of milking machines, P. J. SKERMAN (*Jour. Austral. Inst. Agr. Sci.*, 7 (1941), No. 3, pp. 111-116).—Data are presented on the bacterial contamination of milking machines cleaned by a control method of cold-water rinse, hot-detergent rinse, boiling-water rinse immediately after milking as compared with that in machines where a chlorine solution either replaced the boiling-water rinse in the control method or was used as a supplementary rinse immediately before milking. Chlorine solutions when used at concentrations above 50 p. p. m. of available chlorine were much more effective than the control method in reducing bacterial counts on the various machine parts, particularly when the rinse was used immediately before milking. Calcium hypochlorite proved to be the cheapest source of chlorine and is recommended by the author. Chloramine preparations proved somewhat more stable than either the calcium or sodium hypochlorite, while the last-named was most easily used but was by far the most expensive.

A comparison of Dowicide A and chlorine (Diversol) for use in milking machines, F. W. FABIAN and G. L. NIELSEN. (Mich. Expt. Sta.). (*Jour. Milk Technol.*, 4 (1941), No. 5, pp. 268-275).—In tests extending over 1 yr., rinse solutions of sodium orthophenylphenate (Dowicide A) at concentrations ranging from 1:200 to 1:500 and solutions containing from 102 to 188 p. p. m. of chlorine were effective in reducing the bacterial contamination of milking machines, as indicated by the markedly lower bacterial plate counts of the rinse water and milk from treated machines as compared with similar values for control machines receiving no germicidal treatment. A solution of 1:200 Dowicide A was similar in germicidal potency to the above chlorine solutions. The former was much more stable, being usable for a week or more without significant deterioration. The use of the phenol compound in the milking machine rinse did not affect the phosphatase test of milk samples taken from the treated machine.

The keeping quality of milk powders.—I, Addition of antioxidants, R. WAITE (*Jour. Dairy Res.* [London], 12 (1941), No. 2, pp. 178-183).—Tests were conducted at the Hannah Dairy Research Institute in which 0.1, 0.25, and 0.5 percent of oat flour was added to milk both before and after condensing and also directly to spray-dried milk powder. When used at the lowest concentration the oat flour exerted little antioxidative effect on the butterfat in the milk powder, but 0.25 percent added to the milk, preferably before condensing, increased the resistance of the resultant powder to the development of tallowiness by the equivalent of about 4 mo. at normal temperatures. The highest concen-

tration gave still greater protection against oxidized flavor but imparted a noticeable oat flavor to the milk powder. Hydroquinone, when added to the milk either before or after condensing at a concentration equivalent to 0.5 percent of the weight of butterfat, was highly effective in preventing oxidized flavor development in the milk powder. However, it imparted an objectionable metallic flavor to the powder and reconstituted milk.

**The effect of acidified cans on the quality of dairy products and on the phosphatase value of cream and butter,** A. L. RIPPEN and L. H. BURGWALD. (Ohio State Univ.). (*Milk Plant Mo.*, 30 (1941), No. 11, pp. 55-56, 58, 59).—Milk cans were acidified with a gluconic acid rinse applied by attaching an acid ejector on the last steam jet of the can washer. Acidifying cans to a pH below 6.0 resulted in retardation of the rate of growth of proteolytic bacteria and a fresher odor in the cans when they were wet and allowed to stand for 24 hr. or longer as compared with unacidified cans similarly treated. Considerable bacterial growth occurred in wet cans, however, regardless of the pH, which emphasizes the need of thoroughly drying cans to prevent bacterial growth. No significant difference was noted in the flavor score and bacterial count in raw or pasteurized milk or in the quality of raw cream held in acidified v. nonacidified cans. Butter was churned from various lots of cream held in acidified and unacidified cans. In many cases samples which gave negative phosphatase reactions when fresh became positive during storage, this change being accelerated as storage temperatures increased. These increases in phosphatase value occurred irrespective of the can reaction in which the raw cream was received at the plant.

**A preliminary study of the effects of varying pitching consistency and rate of scald on the physical and chemical properties of Cheddar cheese and on the firmness of the cheese as judged by cheese-makers, bakers, and others,** G. W. SCOTT BLAIR, F. M. V. COPPEN, and D. V. DEARDEN (*Jour. Dairy Res.* [London], 12 (1941), No. 2, pp. 170-177).—Continuing this line of investigation (E. S. R., 85, p. 813), six experimental Cheddar cheeses were made from the same batch of milk and under conditions as similar as possible, except that the consistency of the curd at pitching time—as determined by the Scott Blair method (E. S. R., 84, p. 522)—and, in two cases, the rate of scald were varied. Data are presented on chemical and physical analyses and the judgments of firmness as expressed by cheese makers, bakers, and nonexperts. The results indicate that the consistency of the curd at pitching time and probably the rate of scald are prime factors in determining the firmness of cheese.

**Volatile acids of cheese, I-III** (*Jour. Dairy Res.* [London], 9 (1938), No. 2, pp. 215-226, figs. 3; pp. 227-232; 12 (1941), No. 2, pp. 155-169, figs. 2).—Three reports are noted.

**I. Retentive power of cheese and its constituents,** E. R. HISCOX and J. HARRISON.—Experiments on direct steam distillation of cheese for the recovery of volatile acids indicated that true values are not obtained in this manner. The fat portion of the cheese exerted a retarding effect on the distillation of the higher volatile fatty acids, while the cheese protein proved capable of permanently retaining a part of some of the acids present. It appeared that the steam distillation carried to the point where twice the original volume was collected gave a more accurate picture of the distribution of the acids present in the cheese than could be obtained by distilling to five times the original volume. Distillation apparatus is described.

**II. Methods of extraction,** E. R. HISCOX, J. HARRISON, and J. Z. WOLF.—The experiments reported gave evidence that by water extraction of the cheese and alkaline extraction of the fat, followed by ether extraction of the residues, a

value for volatile acids was obtained which was about  $4\frac{1}{2}$  times as high as that from direct steam distillation in the case of Stilton cheese and about twice as high in the case of Cheddars.

III. *Application of the extraction method*, E. R. Hiscox, J. Harrison, and J. Z. Wolf.—Based on extensive experience with this method, more detailed procedures for the extraction method are presented. A rapid method for the separation of the volatile fatty acids in cheese distillate, based on the relative solubility of the fatty acids in purified butterfat, is also described. Data are presented on the nitrogen distribution and the volatile acids in over 40 cheeses of the white- and blue-veined varieties. On the basis of the distribution of volatile acids, pH, and nitrogen break-down, distinctions could be drawn not only between the white- and the blue-veined varieties but also between Roquefort and Stilton groups of the latter varieties. A high total quantity and a characteristic distribution of the volatile acids appeared to be related to the heavy pricking of cheese of the Roquefort group.

### VETERINARY MEDICINE

[Work in animal pathology and parasitology by the Bureau of Animal Industry] (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt., 1941, pp. 2-4, 7-11, 13, 21-22, 23, 35, 43-92*).—The work of the year reported (*E. S. R., 84, p. 813*) relates to Bang's disease; tuberculosis; phenothiazine as an anthelmintic; coccidiosis of lambs; bovine mastitis; fowl leucosis; avian encephalomyelitis; urinary calculi in calves (*coop. Tex. Expt. Sta.*); incidence of blout in steer calves (*coop. Mont. Sta.*); nicotinic acid deficiency in silver foxes and minks (*coop. Cornell Univ. et al.*); vaccination of pigs with anti-swine-erysipelas serum; eradication of scabies and of dourine; inspection and quarantine of imported animals and products; pullorum disease antigens; tuberculin and other diagnostic tests; disinfectants; infectious equine encephalomyelitis; periodic ophthalmia; swine erysipelas; anaplasmosis; infectious anemia; miscellaneous diseases; stock-poisoning plants; toxicological investigations; tick eradication; hog cholera and its control; virus-serum control; and parasites of horses, ruminants, swine, poultry, and other animals and treatment for their removal.

[Work in animal pathology and parasitology by the Colorado Station] (*Colorado Sta. Rpt. 1941, pp. 20, 33-35, 36-37*).—The work of the year reported (*E. S. R., 84, p. 668*) relates to urinary calculi in feeder lambs, overeating (enterotoxemia) in feed lot lambs, feed lot gains of lambs as affected by drenching, control of coccidiosis in lambs through management, listerellosis and fringed tapeworms in lambs, Bang's disease, and the effects of iron salts on perosis.

[Studies in comparative pathology, etc., in Japan] (*Jap. Jour. Vet. Sci., 3 (1941), Nos. 1, pp. 1-88, pls. 6; 2, pp. 109-222, pls. 11, figs. 4; 3, pp. 241-347, pls. 4, figs. 29*).—Included in the contributions presented in No. 1 (*E. S. R., 85, p. 528*) are the following: Studies on Contagious Pleuro-pneumonia in Cattle—XII, Experimental Infection With Culture of *Asterococcus mycoides*, by S. Yamagiwa, S. Ito, and M. Niwa (pp. 1-22, Eng. abs. pp. 20-22) (*E. S. R., 85, p. 421*); Ein Fall von Pseudotuberkulose bei Schafen [A Case of Pseudotuberculosis in Sheep], by M. Watanabe (pp. 23-31, Ger. abs. pp. 30-31); Beobachtungen von *Sarcoptes*-Räude bei Trampeltieren, I [Observations of *Sarcoptes* Mange in Camels], by Y. Ono and S. Ikeda (pp. 33-42, Ger. abs. pp. 41-42); Der *Dermacentor reticulatus* (Fabricius) Koch, 1844, eine Zeckenart der Kamele aus der Hailar-Gegend in Nordwest Mandschukuo [*Dermacentor reticulatus* (F.) as a Camel Tick in the Hailar Region of Northwest Manchoukuo]

by Y. Ono (pp. 43-48, Ger. abs. p. 48); Studies on Equine Hemolytic Streptococci, Especially on Their Variability, by Y. Ochi and R. Hirao (pp. 49-70, Eng. abs. pp. 69-70); and On the Type Differentiation of Hemolytic Streptococci Isolated From Strangles, Pneumonia, and the Other Streptococcal Diseases of Equines—II, The Type Differentiation by the Serological Examination, by Y. Tuji and A. Sato (pp. 71-88, Eng. abs. pp. 86-88) (E. S. R., 85, p. 529).

Contributions in No. 2 include: Studies on Contagious Pleuro-pneumonia in Cattle—XIII, Histological Investigations on the Experimental Lung-Plague Pneumonia, by S. Yamagiwa (pp. 109-133, Eng. abs. pp. 131-133) (see above); Studies on the Abortion Salmonellosis Among Horses—II, Experimental Cases of the Abortion Salmonellosis, by K. Fukano (pp. 135-153, Eng. abs. pp. 152-153) (E. S. R., 85, p. 520); On the Experimental Haemonchosis of Sheep, by S. Nagahata, J. Fujita, and S. Ikegaya (pp. 155-190, Eng. abs. pp. 189-190); On the Diagnostic Value of the "Stamp Smear Method" in the Case of Cervicitis of Pregnant Mares, by Y. Kawahara (pp. 191-203, Eng. abs. p. 203); and Über die toxische Substanz der Pathogenen Mikroorganismen—I, Die Beobachtung über das Toxin der *Salmonella pullorum* [The Toxic Substance of Pathogenic Micro-organisms—I, Observation of the Toxin of *Salmonella pullorum*], by J. Gotoh and T. Nakayama (pp. 205-222, Ger. abs. pp. 221-222).

Contributions in No. 3 include: Pharmacological Studies on Mallein—I, Action of Mallein on the Excitiated Heart and Its Nature, by Y. Wakamatsu (pp. 241-262, Eng. abs. p. 262); On the Experimental Infection With Rinderpest Virus in the Rabbit—IV, Complement-Fixation Reaction, by J. Nakamura and Y. Goto (pp. 263-286, Eng. abs. pp. 283-286) (E. S. R., 85, p. 520); Studies on the Canine Leishmaniasis in Manchoukuo—I, The Occurrence of the Canine Leishmaniasis in Mukden, by S. Ito, J. Yamashita, and M. Niwa (pp. 287-297, Eng. abs. pp. 296-297); On the Modification of the Fixation of Bacterial Film for Staining, by E. Ryn (pp. 299-308, Eng. abs. p. 308); On the Susceptibility of Rabbit to Artificial Infection of the Glanders Bacilli—I, Bacteriological and Post-Mortem Observations, by M. Watanabe and N. Nakamura (pp. 309-336, Eng. abs. pp. 334-336); and On the Type Differentiation of Hemolytic Streptococci Isolated From Strangles, Pneumonia, and the Other Streptococcal Diseases of Equines—III, The Relation Between Type Differentiation and Virulence Towards Laboratory Animals, by S. Namikawa and A. Sato (pp. 337-347, Eng. abs. pp. 346-347) (see above).

The occurrence of pleuropneumonia-like microorganisms causing arthritis isolated from healthy white rats, H. BEEUWES (*Natuurw. Tijdschr. Nederland. Indië*, 101 (1941), No. 11, pp. 323-324).—The presence of pleuropneumonia-like micro-organisms with arthrotropic qualities in the nasopharynx of healthy white rats is probable. By injecting exudate originating from the paw of a rat infected with arthritis and by cultivation on serum agar it is possible to show the presence of *Streptobacillus moniliformis*.

Studies on the *Listerella* group.—I, Biochemical and hemolytic reactions, P. C. HARVEY and J. E. FABER. (Univ. Md.). (*Jour. Bact.*, 42 (1941), No. 5, pp. 677-687).—Report is made of a study undertaken to determine some characteristic reactions of representative strains of the *Listeria* group under a single set of test conditions. The study indicates that acid is produced from glucose, levulose, galactose, maltose, mannose, rhamnose, trehalose, dextrin, and salicin. Variable results may be obtained with lactose, glycerol, sucrose, arabinose, xylose, mannitol, sorbitol, and starch. Acid is not produced in dulcitol, inositol, raffinose, glycogen, and inulin.

"A possible division of strains on the basis of melezitose fermentation is reported, and a correlation between this and Paterson's agglutinative groups is

suggested. Indole and acetylmethylcarbinol are not produced; nitrates are not reduced. The methyl red test is positive. Beta hemolysis is stated to be characteristic for the genus with the exception of one strain."

**Recovery of virus morphologically identical with psittacosis from thiamin-deficient pigeons,** H. PINKERTON and R. L. SWANK (*Soc. Expt. Biol. and Med. Proc.*, 45 (1940), No. 2, pp. 704-706).

**A new *Salmonella* type, *Salmonella illinois*,** P. R. EDWARDS and D. W. BRUNER (Ky. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 240-242).—Under the name *S. illinois*, description is given of a *Salmonella* type which is represented by seven cultures isolated from three outbreaks of animal disease, namely, of hogs in Illinois, Hungarian partridges in Michigan, and turkeys in Minnesota. The antigenic formula of the bacillus is (III) (XV) XXXIV :<sub>250</sub>—1, 5 . . . .

**Two new *Salmonella* types closely related to *Salmonella muenchen*,** P. R. EDWARDS and D. W. BRUNER (Ky. Expt. Sta.). (*Amer. Jour. Hyg.*, 34 (1941), No. 3, Sect. B, pp. 121-124).—Descriptions are given of two new species of *Salmonella*. The first, *S. oregon*, has the antigenic formula VI VIII: d—1, 2, 3 and is represented by six cultures from hogs and turkeys. The second, *S. manhattan*, has the antigenic formula VI VIII: d—1, 5 . . . and is represented by two cultures from chickens and turkeys. The specific phases of the two types are identical and, while closely related to the specific phase of *S. muenchen*, can be distinguished from the latter by agglutinin absorption tests.

**Stability of a strain of *Salmonella*,** W. L. KULP, R. YOUNG, and R. HOULIHAN. (Univ. Conn.). (*Jour. Bact.*, 42 (1941), No. 5, pp. 643-652).—Experimental attempts to change *S. schottmulleri* flagellar antigenic factors to those of *S. typhimurium* by animal passage are reported. The stability of a fixed type of *Salmonella* could not be appreciably disturbed.

**Studies on staphylococcal toxins,** J. M. WOODWARD and L. W. SLANETZ. (Univ. N. H.). (*Jour. Bact.*, 42 (1941), No. 6, pp. 817-818).

**Effects of sulfanilamide and sulfapyridine upon experimental streptococcal infections,** C. H. HUANG and R. H. P. SIA (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 109-112).

**Some reactions of a pathogenic flagellate, *Trichomonas foetus*, to environmental changes in bacteria-free cultures,** H. S. LYFORD (*Amer. Jour. Hyg.*, 33 (1941), No. 3, Sect. C, pp. 69-87, figs. 5).—Report is made of observations of *T. foetus* in the absence of all other living organisms under conditions which were controlled so far as temperature, food supply, and gaseous exchange were concerned. Some of the biological characteristics of this organism in vitro were determined.

**Cultivation of *Trypanosoma equiperdum* in yolk-sac of developing chick embryo,** E. ALTURE-WEBBER (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 90-92).—Work is reported which has shown that *T. equiperdum* can be cultivated in the developing chick egg by inoculation of infected material into the yolk sac of the egg.

**Studies of phenothiazine, X,** F. DEEDS (U. S. D. A. et al.). (*Soc. Expt. Biol. and Med. Proc.*, 45 (1940), No. 2, pp. 632-634).—In continuation of this series of studies (E. S. R., 85, p. 820), further observations on oxidation of phenothiazine are reported.

**Effect of sulfanilamide and sulfapyridine on antibody formation,** M. M. MASON (*Vet. Med.*, 37 (1942), No. 1, pp. 30-32).—The experiment reported has shown that antibodies can be produced in fairly high titer while experimental animals are under full therapeutic doses of sulfapyridine or sulfanilamide.

**Studies on sulfadiazine, I-III** (*Bul. Johns Hopkins Hosp.*, 69 (1941), No. 4, pp. 297-326, figs. 4).—These studies are presented in three parts.

I. *The chemotherapy of experimental haemolytic streptococcal, pneumococcal, and staphylococcal infections in mice*, P. H. Long, E. A. Bliss, and E. Ott (pp. 297-302).—The studies described have shown that one of the heterocyclic sulfonamide compounds (2-sulfanilamidopyrimidine), to which the name of sulfadiazine has been given, is an effective chemotherapeutic agent in the control of experimental hemolytic streptococcal, staphylococcal, and pneumococcal infections in mice. When equivalent blood concentrations of the drugs were compared sulfadiazine was found to be as effective as sulfanilamide in streptococcal infections and as sulfathiazole in staphylococcal infections, but less effective than sulfathiazole in pneumococcal infections. The inferiority of sulfadiazine to sulfathiazole in the last instance is offset by the greater ease with which relatively high blood concentrations can be produced and maintained with sulfadiazine. When blood levels of 25 mg. percent were obtained by increasing the proportion of the drug in the diet to 0.5 percent, sulfadiazine gave excellent therapeutic results. Moreover, mice tolerated these higher blood concentrations for periods of at least 2 weeks with no apparent ill effects, and showed no pathological alterations in spleen, liver, or kidney which could be attributed to the drug. It is pointed out that it is possible to produce and maintain relatively high blood concentrations of sulfadiazine without injury to the tissues, and because such concentrations have a marked therapeutic efficiency the drug may prove to be very useful.

II. *The clinical use of sulfadiazine in the therapy of bacterial infections other than pneumonia*, G. I. Trevett, R. A. Nelson, and P. H. Long (pp. 303-313).—In the authors' studies sulfadiazine proved to be very satisfactory and effective in the treatment of hemolytic streptococcal infections. The relatively low incidence of toxic reactions encountered in the course of its use led to the conclusion that it is safe to maintain higher blood concentrations of this compound than has been the custom with other sulfonamides. Because it is well tolerated, it appears to be the best available drug for the treatment of chronic bacterial infections which require long continued therapy.

III. *The use of sulfadiazine in the treatment of pneumococcal pneumonia*, F. T. Billings, Jr., and W. B. Wood, Jr. (pp. 314-326).—In 75 cases of pneumococcal pneumonia in which sulfadiazine was employed as the only form of specific therapy all but one recovered.

A list of references accompanies each of the three contributions.

**Absorption and excretion of sulfadiazine**, N. PLUMMER and H. K. ENSWORTH. (Cornell Univ.). (*Soc. Rept. Biol. and Med. Proc.*, 45 (1940), No. 2, pp. 734-738, fig. 1).—In the work reported sulfadiazine was found to be rapidly absorbed into the blood stream, and comparatively high levels of total drug were reached. The proportion of conjugated sulfadiazine in the blood was small. The blood level falls rather slowly after the drug is discontinued. Most of the drug is excreted by the kidney. In four patients given 2 gm. of sulfadiazine and in eight patients given a total of from 7 to 16 gm. the only toxic reaction noted was a morbilliform rash in one case in the latter group.

**Vitamin A deficiencies in ruminants**, H. SCHMIDT. (Tex. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 373-389, figs. 9).

**Terminal cerebrospinal fluid pressure values in vitamin A deficiency**, L. A. MOORE and J. F. SYKES. (Mich. Expt. Sta.). (*Amer. Jour. Physiol.*, 134 (1941), No. 2, pp. 436-439).—In continuation of the work noted (E. S. R., 85, p. 241) it has been shown that when young bovines are fed a vitamin A-deficient ration the cerebrospinal fluid pressures may attain values of 400 to 600

mm. of saline, or four to six times the normal value. These values were obtained with animals at the terminal stage of vitamin A deficiency. In two cases there was a terminal drop in pressure from a previously higher level. Usually the animals in this condition had very little appetite, showed diarrhea, and were more or less in a moribund state so that the drop was not surprising. The increase in cerebrospinal fluid pressure was always accompanied by a marked papilledema, incoordination, and periods of syncope. The condition of syncope often proceeded to a state of convulsive seizure during which respiration ceased for short periods of time. It was felt that the syncope and convulsivelike seizures were due to a cerebral anemia because of the increased cerebrospinal fluid pressure. The fact that excitement often caused these seizures further indicates that this may be true, since it has been shown that a marked increase in pressure accompanies periods of disturbance. The particular cause of the increased cerebrospinal fluid pressure in vitamin A deficiency in the bovine has not been found. Pathological study of the choroidal plexus and arachnoid villi, colloidal osmotic pressure measurements of blood plasma, and various blood and urine analysis have not shown any abnormality which could be related to the raised pressure.

**The effect of dissociation on the electrophoretic mobility of *Brucella*.** T. W. STFARNS and M. H. ROFFKE. (Minn. Expt. Sta.). (*Jour. Bact.*, 42 (1941), No. 6, pp. 745-755, figs. 2).—The authors find electrophoretic measurements under carefully controlled conditions on strains of *B. abortus* dissociated in broth to indicate that dissociation may be a gradual process. Dissociated forms (mucoid) having a greater mobility than the smooth appear after a few days in broth without the complete disappearance of organisms having the mobility values of smooth forms. Longer passage in broth causes further increases in mobility of dissociated forms and the gradual disappearance of organisms of mobility comparable to that of smooth strains. Dissociated forms having appreciably different mobility values may be separated by colony appearance when a given technic is used. The stability of these dissociated forms was not investigated. Passage of dissociated forms of *Brucella* of high mobility through guinea pigs causes a decrease in mobility value to that of the smooth forms without the loss of mucoid character. Serological tests show that mucoid organisms of low mobility are similar antigenically to mucoid forms of high mobility, but are appreciably different from the original smooth organisms. The complexity of the subject of dissociation is emphasized, and lines of further investigation are indicated.

A list of 21 references to the literature is included.

**Calfhood vaccination seen as only an aid in eradicating Bang's disease from cattle.** A. W. DEEM (*Colo. Farm Bul.* [Colorado Sta.], 3 (1941), No. 4, pp. 3-4).—It is recommended that a combined program of vaccination and eradication be employed in the campaign against Bang's disease.

**Testing cattle with johnin** (*Jour. Hyg.* [London], 41 (1941), No. 3, pp. 297-319).—This report on the value of the intradermal test on cattle was made by the British Agricultural Research Council's Committee on Johnne's disease. The comparison between reactions to the double intradermal test with johnin and the post mortem showed (1) an agreement of 23 in 69 positive reactions or 19 in 52 if only those reactions are accepted concerning which there was no difference of opinion, (2) that out of 29 negative reactors 6 were found to have Johnne's disease post mortem, i. e., in 23 was there agreement, or considering only the 17 which were unanimously called negative reactors 6 were positive and 11 negative post mortem, and (3) that if out of the 103 cattle tested only the 20 cases from which Johnne's bacillus was isolated are considered, 10 reacted

positively to both johnin and 2 more to the heat-concentrated johnin, the only johnin used. Two gave doubtful reactions. The reasons for the large disagreement between clinical reaction and post-mortem results are to a great extent speculative.

**Infection of adult cattle with *Mycobacterium tuberculosis avium*, R. E. GLOVER** (*Jour. Hyg. [London]*, 41 (1941), No. 3, pp. 290-296).—A series of 35 unselected cattle tested with synthetic medium tuberculin and synthetic medium johnin was subjected to post-mortem examination. In 5 instances avian strains of full virulence for the usual experimental animals were recovered by the inoculation of guinea pigs with glandular suspensions or by cultural methods used for the isolation of John's bacillus. In 2 of these cases an avian type was isolated from the glands of the alimentary tract and a bovine type from the thoracic glands. In addition, there were 5 cases in which evidence of avian infection was not complete. From 1 a strain was obtained which was culturally identical with an avian type, but it was almost completely avirulent for laboratory animals. In 2, acidfast bacilli were seen in smears from the thoracic and mesenteric glands, respectively, and in the remaining 2, completely calcified glands were observed which were typically tuberculous but were devoid of acidfast bacilli (microscopical examination of smears and sections). Cultures from the organs of guinea pigs inoculated with glandular suspensions from the 4 last-mentioned cases failed to grow tubercle bacilli. In these circumstances the evidence that the infection was of the avian type is largely presumptive, but the nature and extent of the lesions suggests that such may have been the case. With regard to the tuberculin and johnin tests, clear cut reactions to johnin were obtained in 7 instances, a doubtful reaction in 1, and negative reactions in 2. One-half of the animals were also positive to tuberculin.

**Cultural and serological observations on *Vibrio fetus*, W. N. PLASTRIDGE** (Univ. Conn.). (*Jour. Bact.*, 42 (1941), No. 6, pp. 816-817).—In the studies conducted four strains of *V. fetus* were isolated from aborted bovine fetuses from animals free from Bang's disease. "In the presence of an atmosphere containing 10 percent carbon dioxide moderate to heavy growth was obtained in a medium composed of liver infusion, 1 percent peptone, and 0.3 percent agar. Maximum growth resulted after 6 days' incubation at 37° C. and consisted of a heavy band from 4 to 5 mm. in width just beneath the surface. The optimum pH was between 7.0 and 7.4. The minimum depth of the medium required for good growth was from 2 to 3 cm. An agglutination antigen was prepared from 6 day-old cultures. The band of growth was removed with a pipette, diluted with 3 volumes of formalinized (0.3 percent) saline, and centrifuged at 1,600 r. p. m. for a period of 30 min. The cloudy supernatant fluid was removed and centrifuged in an angle centrifuge at 3,200 r. p. m. for 30 min. The sedimented cells were suspended in a small amount of formalinized saline. The suspension was diluted for use in the tube agglutination test to a density of 1.0 on the McFarland nephelometer scale. The blood serum of 5 cows which aborted fetuses from 3 to 7 mo. of age gave agglutinin titers of from 1 to 200 to 1 to 800, and 1 which aborted a 2-month-old fetus was negative to the test. These and other data obtained on 131 animals in four infected herds and on 221 animals in three herds regarded as free from *V. fetus* suggest that a titer of 1 to 200 or higher indicates infection, that a titer of 1 to 100 should be regarded as suspicious, and that a titer of 1 to 50 or lower is not significant."

**Studies on bovine gastrointestinal parasites.—V, Immunity to the stomach worm, with a note on the prepatent period, R. L. MAYHEW.** (La. Exptl. Sta.). (*Amer. Jour. Hyg.*, 33 (1941), No. 3, Sect. D, pp. 103-111, figs. 3).—In continua-

tion of this work (E. S. R., 86, p. 388), description is given of inoculations with the stomach worm *Haemonchus contortus* which resulted in setting up a reaction similar to that developed against the nodular worm *Oesophagostomum radiatum* and the hookworm *Bunostomum phlebotomum* (E. S. R., 84, p. 394). In the experiments conducted, in which immunity developed to the stomach worm in six calves as judged by egg counts in eggs per gram of sediment, the immune reactions were initiated at the time adult worms were present and when the animals were reinoculated and immature larvae were present. That the sudden decreases in egg counts are associated with the initiation of the immune reaction and not due to a loss of worms from old age is suggested by the data on calves. That the immune reaction is not associated with degree of infection is indicated by the fact that the various animals had average egg counts preceding its initiation.

**Some factors affecting the incidence of calf scours, W. T. S. THORP, J. F. SHIPLEY, and M. A. FARREL.** (Pa. Expt. Sta.). (*Vet. Med.*, 37 (1942), No. 1, pp. 34-35).—Observations made over a 2.5-yr. period on cases of calf scours in a large dairy herd are reported. It was found that where the affection is a serious problem in a high producing herd, the regulation of the intake of the dam's milk tends to reduce the incidence and severity of the syndrome. A specific serum was necessary to check the severe outbreak encountered. After the scours had been brought under control the routine use of commercial serums at birth gave satisfactory results. The medicinal treatment of calves 2 to 3 days old was not highly successful where a large number of calves were affected. Medicinal treatment of calves over a week old has proved more satisfactory.

**Calf scours, C. F. CLARK** (*Michigan Sta. Quart. Bul.*, 24 (1941), No. 2, pp. 99-100).—A popular discussion.

**A note on the effect of repeated doses of phenothiazine on sheep, W. L. WRIGHT.** (Univ. Ill.). (*Vet. Med.*, 37 (1942), No. 1, p. 33).—It was found that a single 25-gm. dose and six weekly 25-gm. doses of phenothiazine did not affect the blood hemoglobins and weight gains of yearling lambs and caused no pathologic constituents to appear in the urine.

**Test of drenching feedlot lambs continued this year; last year's results described, G. S. HARRSFIELD and I. WATSON** (*Colo. Farm Bul.* [Colorado Sta.], 3 (1941), No. 4, pp. 10-12).—In order to determine (1) whether the drenching of lambs for removal of parasites is a profitable practice and (2) the efficiency of commonly used treatments, three groups each of 22 lambs were tested from November 25, 1940, to March 24, 1941. To the first group, phenothiazine (10 gm. per pound of body weight) was given; to the second group, a mixture of 1.5 percent copper sulfate and 0.4 percent nicotine sulfate at the rate of 1 cc. per pound of body weight was administered; and the third group was used as a check. A determination of the efficiency of the drugs in removing the parasites, made by counts of the worm eggs in the feces before and after treatment showed that in both treated lots there was a reduction in the numbers of parasite eggs to about one-third of the number being eliminated before treatment. Stated in percentage efficiency of the treatments against the Trichostrongylinae (roundworms) as a group, phenothiazine was 73.3 percent and copper sulfate-nicotine 87.8 percent efficient in removing all the worms. The phenothiazine-treated lambs showed 0.02 lb. increased daily gain, with 80 ct. per hundredweight decrease in cost of market gain, but 20 ct. per hundredweight decrease in market appraisal value (based on dressing percentage and finish) per lamb as compared with the untreated lot. The copper sulfate-nicotine-treated lambs showed 0.02 lb. greater daily gain, with the cost of

market gain reduced 70 ct. per hundredweight, but a market appraisal decrease of 30 ct. per hundredweight when compared with the check lot. The profit per lamb was 14 ct. greater in the phenothiazine-treated group than in the untreated group. There was little difference in profit in the untreated and the copper sulfate-nicotine-treated lambs.

**The reticulo-endothelial system and immunity in hog-cholera, H. C. II. KERNKAMP.** (Minn. Expt. Sta.). (*Jour. Immunol.*, 39 (1940), No. 1, pp. 85-88).—In the study reported the mechanism which functions in immunity in hog cholera, presumed to be the reticulo-endothelial system, was not disturbed by blocking it with trypan blue. Pigs whose reticulo-endothelial systems appeared to be completely blocked could be immunized against hog cholera by the antiserum-antigen treatment as effectively as others in which no interference was attempted.

**A hemophilia-like disease in swine, A. G. HOGAN, M. E. MUHRER, and R. BOGART.** (Mo. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 217-219).—Description is given of an affection of swine that has occurred for a number of years in a number of swine in the Missouri Station herd in which death has resulted from hemorrhage, either spontaneous or as a result of minor wounds. All of the affected animals were closely related. The symptoms resemble hemophilia more closely than any other known affection.

**Incidence of *Trichinella spiralis* in garbage-fed hogs in San Francisco, J. B. McNAUGHT and E. M. ZAPATA** (*Soc. Expt. Biol. and Med. Proc.*, 45 (1940), No. 2, pp. 701-704).—Examinations made of the diaphragms of 495 garbage-fed hogs received in two abattoirs in San Francisco revealed 4.04 percent to be infected with *T. spiralis*. This figure is comparable with similar surveys of garbage-fed hogs in other areas of the United States but is 20 times higher than has been found in garbage-fed hogs in Canada, where garbage is cooked before feeding.

**A note on the effect of large doses of phenothiazine on draft horses, L. E. BOLEY, C. C. MORRILL, and N. D. LEVINE.** (Univ. Ill.). (*Vet. Med.*, 37 (1942), No. 1, pp. 26-29, fig. 1).—In a study of the effect of phenothiazine on Percheron horses, no significant change appeared in the urine or blood hemoglobin of an animal fed 80 gm. The blood hemoglobins of two horses fed 160 and 400 gm., respectively, were lowered, but no significant change in the urine constituents was observed. One horse with carcinoma of the penis which had been fasted for 5 days died 3 days after being fed 324 gm. of phenothiazine. A marked variation averaging 2.13 gm. per 100 cc. of blood was observed in the blood hemoglobins of untreated horses from one bleeding to the next, and the consequent necessity for repeated rather than single determinations in a study of the effect of phenothiazine on the blood hemoglobin was indicated.

**Neutralizing antibodies against St. Louis and western equine encephalitic viruses in horses and fowl, B. F. HOWITT and W. VAN HEMACK.** (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 247-250).—In continuation of earlier study (E. S. R., 86, p. 94), the authors report having found about 26 percent of 69 serums of encephalitic patients in the central valley areas of California to be positive to both the western equine virus and that of the St. Louis encephalitic type. In determining whether a similar relationship existed with animals, neutralization tests were performed on serums of domestic fowl and horses collected from endemic and presumably nonendemic areas of California. Antibodies against the St. Louis virus were found present in the blood of many horses and domestic fowl, and with a few exceptions they were in association with the neutralizing substance against the western equine virus. Of 43 unvaccinated normal horses and 2 recovered ani-

imals from the endemic regions of Kern, Fresno, and Yolo Counties, all except 2 showed neutralizing antibodies against the western equine virus. With the exception of 10, the serums were positive to the St. Louis virus as well, but none was positive to the latter alone. Serums were tested from 10 horses vaccinated against the equine strain in a northern California area. All were positive to the homologous virus but were negative to that of the St. Louis. Of 3 unvaccinated animals, 2 were negative to both strains and 1 weakly positive to the equine. Many of these horses had been imported from the East and therefore had not been long exposed to the western environmental factors. "It is difficult to decide as to the significance of the antibodies to both of these viruses among apparently healthy domestic animals, especially when it had been found that fowl without neutralizing substances were often insusceptible to either virus. . . . At present there is apparently a correlation between certain environments contributing the clinical disease in man and horses and the development of antibodies to both viruses in the blood of fowl and horses. A common vector or common reservoir may be responsible for both apparent and inapparent infections."

**The infectious cycle of avian encephalomyelitis (epidemic tremor),** E. L. MINARD and E. JUNGHER. (Univ. Conn.). (*Jour. Bact.*, 42 (1941), No. 6, p. 817).—In the study here reported adult birds from known avian encephalomyelitis-infected flocks appeared to carry the virus. Typical histologic lesions resulted from intracerebral inoculation of chicks with suspensions of the ovary, oviduct, liver, and pancreas from 1 of 6 birds and filtered fecal suspensions from 26 of 66 birds from three flocks. Chick embryos inoculated with avian encephalomyelitis at various ages and by various routes proved susceptible. Thus the presence of the virus in tissues and feces of adult birds and its passage through the egg is indicated.

**The pathology of equine encephalomyelitis in young chickens,** H. E. TYZZER and A. W. SELLARDS (*Amer. Jour. Hyg.*, 33 (1941), No. 3, Sect. B, pp. 69-81, figs. 8).—Report is made of the pathology of the eastern type of the equine encephalomyelitis virus as studied in the mouse, guinea pig, young rat, vole (*Microtus pennsylvanicus pennsylvanicus*), deer mouse (*Peromyscus leucopus*), very young Rhode Island Red chickens, and several young adult ring-necked pheasants and common quail or bobwhite. Changes in the central nervous system in young rats and voles were in most respects quite similar to those found in the guinea pig by King (*E. S. R.*, 80, p. 398).

**Hemorrhage control in *Eimeria tenella* infected chicks when protected by anti-hemorrhagic factor, vitamin K,** F. M. BALDWIN, O. B. WISWELL, and H. A. JANKIEWICZ (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 278-280).—In the work reported the administration of vitamin K in the dietary of chicks definitely decreased the mortality in chicks parasitized by *E. tenella*, a hemorrhage-producing protozoan, since all autopsies performed show the vitamin K-protected birds had a fibrinated core in the ceca which was in the process of being reabsorbed. Vitamin K-protected birds showed a mortality of only 10 percent in comparison with 70-percent mortality in the unprotected group.

**The modification of infectious bronchitis virus of chickens as the result of propagation in embryonated chicken eggs,** J. P. DELAPLANE and H. O. STUART (*Rhode Island Sta. Bul.* 284 (1941), pp. 20).—The work reported, details of which are given in tables, shows that "infectious bronchitis virus can successively be obtained from the lower trachea of infected chickens bacterial-free and suitable for egg propagation purposes without passage through bacteriological filters. No distinctive or characteristic lesions of the embryo are noted during the first few egg passages of the field strain of the virus, although growth may be proved

to have occurred by permitting some of the inoculated eggs to hatch, in which instance some of the chicks will show the typical symptoms of the disease at the time of hatching. With each succeeding transfer the virus becomes more virulent for the embryo. The lesions noted are whitish foci on the liver, congestion and swelling of the kidneys, whitish opaque circular lesions on the chorioallantoic membrane (at the point where the virus is inoculated) of those embryos living for 3 or more days, and a tendency of the chorioallantoic membranes to appear thinner than normal and to adhere to the shell. Occasional hemorrhages will be noted scattered over the skin of the embryos, as well as marked smallness of sizes of the embryos. As the egg passages were continued, the embryo mortality was noted particularly on the fifth and sixth days; then the fourth, third, and finally the bulk of the embryos [was] killed by the end of the second day. The ability of the virus to kill embryos appears to become fixed so that no further changes in this respect are noted. This change occurs at about the sixty-fifth generation and remains constant up to and including the ninetyeth transfer. The results as far as the effects on the embryos are concerned are substantially in agreement with the findings of Beaudette. No particular outstanding differences were noted with the B-588 virus as far as its effect on the embryo could be noted.

"The Rhode Island strain of the virus ceased to be virulent for baby chicks exposed by spraying or inoculation of the virus in the bursa at the eighty-ninth, ninetieth, and ninety-first passages. Chicks exposed to such a virus by spraying or inoculation of the bursa of Fabricius were susceptible to a virulent virus 10 days and 2 weeks following exposure to the attenuated virus, thus indicating that such an attenuated virus does not stimulate immunity by the methods employed. When inoculated in the nasal cavity, mild but typical symptoms of the disease were noted after a period of 2 weeks. The B-588 virus remained capable of inciting typical symptoms of the disease in baby chicks at the one hundred and twentieth to one hundred and twenty-fifth generation transfers (our eightieth to eighty-fifth transfer) during the winter months, indicating that seasonal variations may influence the activity of the virus. The reisolated virus from chickens infected with the B-588 virus failed to indicate that such a passage had caused it to revert to the field type as indicated by the results of egg inoculation tests. The virus survived storage in the fresh frozen state when kept frozen for 4 and 4.5 mo., but not for 5.5 mo. as indicated by egg tests. It survived when held at room temperatures for 5 to 7 days, but not for 14 days and at 50° C. for 5, 10, and 15 min. as indicated by egg inoculation tests."

The effect of intraperitoneal injections of carbon ink on the course of *Plasmodium lophurae* infections in chickens, W. TRACLER (*Amer. Jour. Hyg.*, 34 (1941), No. 3, Sect. C, pp. 141-149, figs. 2).—When 4- to 9-week-old chickens were inoculated with large doses of *P. lophurae* the parasite number usually reached a peak on the third day and then rapidly decreased. In similar chickens which received carbon ink in the posterior peritoneal cavity the parasite number continued to increase beyond the third day, reached a peak, usually higher than in control chickens, on the fifth day, and then fell off less rapidly than in untreated chickens. The course of the infection in the treated chickens resembled that seen in very young chicks, suggesting that the ink treatment interfered with the mechanism responsible for the age immunity observed in untreated older chickens.

A new drug effective against bird malaria, R. IEGNER, E. WEST, M. RAY, and M. DOBLER (*Amer. Jour. Hyg.*, 33 (1941), No. 3, Sect. C, pp. 101-111, figs. 9).—Experiments since 1922 in the search for a drug that would be equal to or

more effective than quinine in the treatment of malaria in birds led to the finding of such in the new drug hydroxyethylapocupreine dihydrochloride. Three species of bird malaria organisms were used in the experiments, namely, *Plasmodium lophurae*, Coggeshall strain, in young Peking ducks; *P. relictum*, Coatney strain, in pigeons; and *P. cathemerium*, Hartman-Hewitt strain, in canaries. This drug was much less toxic than quinine hydrochloride, but the two were about equally effective against *P. lophurae* in ducks. Large doses of the new drug were more effective against *P. lophurae* in ducks than smaller doses, but very large doses were not much more effective than large doses. Administered orally or intravenously, it was effective against *P. relictum* in pigeons, and it was about as effective as quinine hydrochloride against this parasite in pigeons. The two drugs were also about equally effective against *P. cathemerium* in canaries.

**Control of malaria infection (*P. lophurae*) in ducks by sulfonamides,** H. A. WALKER and H. B. VAN DYKE (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 368-372).—Infection of the young Peking duck with *Plasmodium lophurae* usually progresses with rapid multiplication of the parasites in the blood and death after 5-16 days, as reported by Hegner et al. above, or 7-10 days, as found by the authors. When sulfonamides (sulfathiazole or sulfadiazine) are administered by incorporation in the food, the multiplication of parasites is checked after a few days and the birds survive at least several weeks with relatively few or, occasionally, no parasites in the blood. Sulfanilamide appears to be less effective.

**Comparison of the egg production and rate of gain of birds negative and positive to the pullorum test,** L. G. NICHOLSON and E. C. McCULLOCH. (*Wash. Expt. Sta.*). (*Vet. Med.*, 37 (1942), No. 1, p. 44, figs. 2).—In the comparison made six adult nonreactors selected from a farm flock and six reactors in a dilution of 1:100 to the whole blood serum plate and tube agglutination tests from the same flock, all selected at random, were placed in individual metal cages and received the same care. Daily records of individual egg production were made for 3 mo., and the averages for 10-day periods revealed the production of the reactor birds to have been from 8.4 to 44.7 percent lower than that of the negative birds.

**Studies on the cultivation of *Sp[irochaeta] gallinarum*,** I. J. KLIGLER and D. KAPLAN (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 103-106).—The results of a systematic study of the nutritive requirements of the causative organism of fowl spirochetosis are summarized. A description is given of the medium in which the organism can be cultivated without difficulty.

**Studies on the occurrence, epidemiology, and inter-host relationships of nematode parasites of the chicken (*Gallus gallus*) in Alabama** (*Alabama Sta. Rpt.* 1940, p. 43).—Further studies by R. O. Christenson are noted (*U. S. R.*, 85, p. 539).

**Prevention and control of poultry diseases and parasites,** W. J. LISTOR and C. F. ROWE (*Ariz. Univ. Expt. Ctr.* 112 (1941), pp. [2]+33, figs. 6).

## AGRICULTURAL ENGINEERING

**[Agricultural engineering investigations at the Colorado Station]** (*Colorado Sta. Rpt.* 1941, pp. 49-54).—Snow surveys (coop. U. S. D. A. et al.) are noted; also results of experiments with high-strength wire for reinforcing precast concrete beams, in which adequate reinforcement was provided by about one-half as much steel as is required in conventional design; photographic method of making snow surveys; and sugar beet machinery work, including single seed planters, experiments on mechanical thinning, and a variable depth planter.

**Investigations of methods and equipment used in stream gaging.—Parts 1, 2, C. H. PIERCE** (*U. S. Geol. Survey, Water-Supply Papers 868-A (1941), pp. IV+35, pls. 27, figs. 3; 868-B (1941), pp. IV+37-75, pls. 4, figs. 6*).—In part 1, *Performance of Current Meters in Water of Shallow Depth*, the author reports upon an investigation made primarily for the purpose of determining coefficients to be applied as correction factors to velocities measured in very shallow water. The discharge as measured by the current meter was compared with weir or venturimeter discharge measurements to obtain the correction factor. Current-meter measurements over beds of smooth concrete,  $\frac{3}{4}$ -in. gravel, and coarse gravel were investigated. Data from studies of pulsations, vertical velocity curves, distribution of velocities near the side walls of the flume, and performance of current meters near the water surface and near the flume walls were used in analyzing and interpreting the results of the discharge measurements.

In the work reported in part 2, *Intakes for Gage Wells*, about 90 different devices and arrangements of intakes were tested at the National Hydraulic Laboratory with respect to their performance and with reference especially to their effectiveness in eliminating draw-down. The results are tabulated. Several devices were selected by the laboratory committee of the Geological Survey for recommendation to the district engineers of the Survey as being effective in eliminating draw-down at stations for the measurement of stream flow. Working drawings of these show structural detail.

**Geology of dam sites on the upper tributaries of the Columbia River in Idaho and Montana.—Part 1, Katka, Tunnel No. 8, and Kootenai Falls dam sites, Kootenai River, Idaho and Montana, C. E. ERDMANN** (*U. S. Geol. Survey, Water-Supply Paper 866-A (1941), pp. V+36, pls. 7, fig. 1*).—The Katka site, Boundary County, Idaho, appears to be the best natural location for a high dam to control the Kootenai River in the United States, but the favorable features are nullified by the presence of the railroad at low elevations. Tunnel No. 8 site, Lincoln County, Mont., has geologic and cultural conditions that make it unsuitable as a dam site. The Kootenai Falls sites, Lincoln County, Mont., have favorable geologic conditions and can be developed without endangering the railroad.

**Geology and ground-water resources of the Balmorhea area, western Texas, W. N. WHITE, H. S. GALE, and S. S. NYE** (*U. S. Geol. Survey, Water-Supply Paper 849-C (1941), pp. III+83-146, pl. 1, figs. 2*).—The geology of the water-bearing formations is discussed, as are also the intake and discharge of ground water.

**Surface water supply of the United States, 1939.—Part 1, North Atlantic slope basins** (*U. S. Geol. Survey, Water-Supply Paper 871 (1941), pp. XIII+603, pl. 1*).—This paper records measurements of stream flow in these basins for the year ended September 30, 1939.

**Underground leakage from artesian wells in the Las Vegas area, Nevada, P. LIVINGSTON** (*U. S. Geol. Survey, Water-Supply Paper 849-D (1941), pp. III+147-173, pls. 6, fig. 1*).—From observations in 42 wells explored with a current meter designed for measuring the flow at various points in deep wells, it is concluded that the aggregate leakage from wells is not great enough to be responsible for more than a small part of the serious decline in water levels and artesian pressure in the basin. Great quantities of water are allowed to flow from the wells without being used beneficially or economically, however. It is believed that if the draft on the artesian basin were reduced and strict measures of conservation were applied, the pressure would increase noticeably, especially in the shallower sands.

**Aids to judgment in irrigation, F. E. STAEBNITZ.** (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 4, pp. 129-131, 136, fig. 1).—The record of rainfall is an imperfect guide, but one that should not be entirely overlooked. In apple orchards it has been found that the rate of increase in the volume of the fruit may be a valuable index of the occurrence of moisture deficiency. Lemons have also shown retardation in rate of fruit growth when water shortage developed. The author suggests the use of a simplified form of atmometer, with no valve to prevent return of rainfall to the reservoir so that the effect of rainfall on the instrument may be more nearly like its effect upon the plant. He also discusses soil pressure and tension indicators and the electrical resistance ground-water meter.

**Controlled drainage, D. H. HARKER.** (Purdue Univ.). (*Agr. Engin.*, 22 (1941), No. 4, pp. 139-142, figs. 4).—The author outlines drainage systems so designed as to provide both adequate removal of water during spring rains and impoundment of drainage water at the end of the period in which drainage is required so as to prevent late summer drought. Dams in the open channels and stop wells in the tile systems are used where only the drainage water is available, but a supply of fresh water is also to be desired.

The dams must have floodway sufficient to pass the maximum discharge of the open channel, must go well into the banks and well below the channel bottom to prevent danger of damage to the structure, and must have lateral stability to withstand the water pressure and a paved spillway to prevent undercutting. Crest boards are preferred to bulkheads or vertical windlass gates. Such gates require considerable power for operation and almost constant attention and adjustment to maintain a desired water-table level. The stop well consists of a concrete box about 3 ft. square inside, as deep as depth of the tile line, or from 18 to 24 in. deeper than the outlet tile if a catch basin for silt is desired. Planks can be dropped into 2-in. wide grooves formed from the bottom to the top to form a dam crest. Materials and type of construction for dams are briefly considered, the conclusion being that, in general, a concrete structure with crest boards and a piling cut-off wall may be the cheapest and best when durability is considered. For low dams in small streams, wooden or corrugated sheet steel may best be used.

In addition to the prevention of drought injury to crops, controlled drainage has, in muck soils, the advantages of control of wind erosion and the lessening of the danger of muck fires.

**Equipment for terrace construction, J. T. McALISTER.** (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 4, pp. 147-148, figs. 3).—The author calls attention to the great magnitude, in the aggregate, of the earth-moving job involved in the adequate terracing of the farms of the United States, defines the requirements of the drainage-type terrace, now the most commonly built terrace in the southeastern area, and discusses recent developments and relative suitability of the implements and machines used. Since 1933 heavier equipment, drawn by track-type tractors of from 40 to 50 hp., has been replacing some of the light horse-drawn and farm-tractor equipment in connection with efforts to accelerate progress of the soil conservation program.

Terrace construction and maintenance, while representing a great undertaking in the aggregate, are relatively simple problems of the individual farm. Best results are obtained when the work required becomes a part of the regular farm operations. Since terrace construction is basically a problem of earth moving, any type of equipment selected for this purpose should be evaluated on its capacity for economical movement of earth under the varying soil conditions encountered.

**Physical reactions of tillage tools causing compression and arch formation, and analyses of plow moldboard shapes and materials (Alabama Sta.**

*Rpt. 1940, p. 16*).—A new method of measuring and studying compression and arch action developed by F. A. Kummer.

**Harvesting grain sorghums, F. C. FENTON.** (Kans. State Col.). (*Agr. Engin.*, 22 (1941), No. 4, pp. 137-138, 142, figs. 4).—The grain sorghum produces grain in a head held well above the leaves so that hand or machine methods of harvesting are easily performed. Hand topping is considered practicable for small acreages and was reported as the method used for harvesting half of the crop in the Southwest in 1927, but mechanical harvesting has increased since that date, mainly because of the now almost universal use of the combine for wheat. The author discusses also the standard row binder, described as the most practical method for the tall varieties grown for forage as well as for grain; the header, a very successful harvesting method for dwarf varieties but less used than formerly because the header has almost gone out of use in wheat harvesting; and the combine harvester, the use of which is extensive for wheat and therefore desirable for grain sorghums. To prevent throwing the heads from the platform, the reel slats may be widened by adding wide pieces of light-weight siding. The header-dump box combination developed at the Fort Hays Substation has been used successfully for a number of years. The piles dropped by the dump box are placed in windrows for ease in threshing. The combine is pulled along a row of these piles, and the heads pitched onto the platform canvas. Lodging caused by strong winds after a heavy freeze drops a rather large percentage of the grain below the reach of the combine, and efforts to avoid this loss have resulted in some combining before the grain is dry enough for safe storage. Cylinder speeds should be reduced to from two-thirds to three-fourths of those used for wheat threshing to avoid cracking. Both the angle-bar and the rasp-bar types of cylinder have given good results in threshing sorghums and appeared to crack less grain under most conditions, if properly adjusted, than did the tooth cylinder and concave. Combines having the rasp-bar type of cylinder will crack a large part of the grain if set too close and run at high speed, however.

**Machines designed for harvesting and storing grass silage, H. E. BESLEY and W. R. HUMPHRIES.** (N. J. Expt. Stat. and U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 4, pp. 125-126, figs. 5).—The grass-silage crop weighs about three times as much as field-cured hay, and pitching it is laborious. Hay loaders have been so redesigned as to give little trouble in loading green grass. The tractor mower cutting a 6-ft. swath will keep three trucks and a loader busy. Cutting grass silage with a standard grain binder, eliminating need for the loader, has been successfully tried, especially with timothy and the small grains. When gathering from the swath, loaders tend to pick up from adjacent swaths, especially hillsides. This tendency may quickly build up, resulting in clogging and possible damage. Most cutters are considered to be now equipped for handling grass silage satisfactorily, whether pitched from a load or from the ground. Molasses used as preservative caused less inconvenience when applied above the shear plate or at some other point in the fan housing rather than at or ahead of the feed roll. Field choppers were found to save labor but to cost too much, at present, except for large-scale operations. The new small harvester having feeders of a small combine and serving as mower, chopper, and loader is considered capable of going a long way in reducing the cost and hard labor involved in the production of grass silage. Tests made in New Jersey with an experimental model during the past summer indicate that the outfit operated by two men can harvest from 3 to 5 tons of second-cutting alfalfa an hour. Later tests with an improved model showed much greater capacity. Work with an experimental elevator of the drag type, with

flights enclosed, showed that fast-moving lifts knock out considerable material when fed from the front either by gravity or from the feed table. Slower speeds reduced the throwing of the silage but introduced wedging difficulties. Performance of some promise was obtained by entirely enclosing the elevator at the bottom and feeding from the side, between the flights, above the point of enclosure. A metal housing was provided without clearance between the housing and travel of the lifts.

**A practical seed-cotton moisture tester for use at gins,** G. E. GAUS, C. S. SHAW, and W. H. KLEVER (*U. S. Dept. Agr. Cir. 621 (1941), pp. 26, figs. 11*).—The tester is designed to register the hygrometric condition of the air confined within a mass of seed cotton by means of wet-bulb and dry-bulb thermometers, over which the air to be tested is drawn by suction provided by a vacuum cleaner. Drawings and a bill of material for the construction of the tester, from standard pipe fittings and inexpensive accessories, are included. A conversion table gives equivalent moisture content corresponding to the range of relative humidities indicated by the tester when used with seed cotton. A coefficient of correlation with drying-oven moisture determinations of 0.94 and a standard error of estimate of 1.48 percent were found.

A moisture-content calculator employing a set of adjustable wet-bulb and dry-bulb temperature integrating scales for direct reading of corresponding moisture content from temperature readings made with the moisture tester is also described. A bill of material and specification for the construction and assembly of the calculator are included, and it is shown in photographs but not in working drawings.

**Set-up in rural electrification technology needed,** S. P. LYLE. (U. S. D. A.). (*Agr. Engin., 22 (1941), No. 4, pp. 135-136, fig. 1*).—This brief discussion emphasizes the need for an increased rate and volume of technological investigation to keep pace with the rapid progress of the rural-electrification project as a whole. Without this increase in research the growth of rural electrification will be retarded or checked.

**Needed research on southern farm buildings,** W. V. HUKILL. (U. S. D. A.). (*Agr. Engin., 22 (1941), No. 4, pp. 127-128, figs. 2*).—This is a brief, general discussion of subjects needing investigation as they are brought out by letters of inquiry, etc. These include moisture control, use of building materials, sanitation, and the general requirements to be met in storage houses, in livestock buildings, and in other structures. While these subjects are more or less interrelated, each includes a number of items which should be included in any list of needed research. The larger problem of actually getting improvements on farms where they are needed is implied in all the inquiries and needs special attention.

**Hog barn heating and ventilation,** A. SEVERSON (*North Dakota Sta. Bimo. Bul., 4 (1941), No. 2, pp. 13-14*).—To prevent concrete floors from becoming too cold, especially during farrowing, the author used warm-air runways under the floor. Those here described were placed 1 ft. apart, each was made 18 in. wide and 8 in. deep, and the ducts were placed 4 in. below the surface. Air heated by a stove at one end of the barn was driven through these ducts by a booster fan and was returned to the furnace. The ducts were placed under the farrowing pens and were designed to maintain a floor temperature of about 102.5° F., the body temperature of the animal. The importance of insulating the foundation walls, as, for example, with a 2-inch layer of mixed asbestos powder, vermiculite, and cement poured inside the foundation walls, is emphasized. Heating and ventilation should be carefully considered either in building a new hog house or in remodeling an old one. Draftiness must be avoided, but building up an excessive concentration of carbon dioxide and too a high humidity through inadequate ventilation may cause pneumonia.

**The all-electric greenhouse, J. ROBERTS and S. E. WADSWORTH** (*Washington Sta. Bul.* 404 (1941), pp. 22, figs. 13).—This bulletin mentions the lean-to, the separate all-glass, and the insulated types of electric greenhouses but is mainly concerned with the construction of the last-named type. A bill of materials for a standard 8- by 12-ft. house shows also the additional quantities of each dimension of lumber and of other materials required for each 3-ft. increase in length. The unit described is to be framed of 2- by 4-in. lumber. All-weather plywood is to be applied inside and outside the frame, insulation being placed between the two plywood layers. Working drawings show the detail of construction. Heat was found to be satisfactorily supplied by a 1,300-w fan air heater and two 400-w soil-heating cables laid one in each soil bench. The heating elements are to be thermostatically controlled. Data obtained in tests of electric-power requirement are tabulated. The approximate costs of construction are given. Related topics taken up are soils for the greenhouse bench, flowers suggested for the small electric greenhouse, vegetables, artificial light, and suggestions for operating the electric greenhouse.

**Housing requirements for curing tobacco, J. M. CARR** (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 4, pp. 133-134).—The author outlines the flue-curing process and points out the need for improvement in design both of buildings and of heating equipment, the buildings needing, especially, better insulation and the heating equipment an application of known principles of drying technique, avoiding formation of "chimneys" in the tobacco due to poor heat distribution and resulting in still less uniform drying. The fire hazard is especially emphasized, as is the need for protecting the cured leaf from wide variations in temperature and humidity and from direct or strong light. Similar problems relating to air curing, buildings for grading, etc., are noted.

**Some development trends in the farm freezing and storing of food, G. W. KABLE** (*Agr. Engin.*, 22 (1941), No. 4, pp. 143-146, figs. 2).—The author considers that not all of the farm-frozen products are as good as those which have been grown, harvested, and frozen under expert commercial supervision, but in most cases frozen farm products have been much more acceptable than the same products canned. He summarizes current practice in this type of food preservation and marketing.

## AGRICULTURAL ECONOMICS

**[Investigations in agricultural economics by the Alabama Station, 1940]** (*Alabama Sta. Rpt.* 1940, pp. 7, 8-15).—Included are some findings, usually in the form of a summary table with discussion, for studies made in Marion County, by B. T. Lanham, Jr., and W. F. Lagrone, on use of short-term farm credit; availability and use of farm family labor; variations in annual work stock costs by size of farms; investment in land and buildings by size of farms; farm machinery and equipment by size of farms; credit advances to sharecroppers; approved soil-building practices carried out; and farm costs of operating automobiles and trucks.

**[Investigations in agricultural economics by the Colorado Station, 1941]** (*Colorado Sta. Rpt.* 1941, pp. 45-46).—Included are: (1) Brief general findings based on analyses of financial records and feed-lot costs for lambs and cattle in the irrigated districts of the northern parts of the State; (2) findings as to net cash income, total net farm gain, average yields of corn and wheat, etc., in 1939 on 20 first-grade dry-farm operating units in northeastern Colorado; and (3) findings as to average cash farm receipts, cash farm expenses, and farm living expenses in 1939 as shown by the records of 50 U. S. D. A. Farm Security Administration clients.

**Current Farm Economics, [December 1941]** (*Oklahoma Sta., Cur. Farm Econ., 14* (1941), No. 6, pp. 161-203, figs. 10).—In addition to the usual discussion of the agricultural situation and usual tables of indexes, etc., articles are included as follows: World War II, by R. T. Klemme (pp. 169-173), discussing some of the problems the war presents to agriculture; Export Trade and American Agriculture, by G. P. Collins (pp. 173-184), discussing briefly the early development in agricultural exports, the present status, and the outlook; and Conservation on Small Cotton-Corn Farms, by E. A. Tucker (pp. 185-199), which summarizes and discusses some of the findings in a study of the Pecan Creek Demonstration Area of Muskogee County.

**Foreign Agriculture, [November-December 1941]** (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr., 5* (1941), Nos. 11, pp. 443-488, figs. 2; 12, pp. 489-534, figs. 6).—No 11 includes an article on Agriculture in the Argentine Trade Agreement, by L. C. Nolan (pp. 445-468), discussing the background of the Argentine-United States trade and the agricultural concessions granted to Argentina and the United States in the trade agreement effective November 15, 1941; and an article on Mexican Vanilla Production and Trade, by L. D. Mallory and W. P. Cochran, Jr. (pp. 469-488).

No. 12 includes articles on The Agricultural Economy of Colombia, by K. H. Wylie (pp. 491-514), and The Japanese Silk Industry Faces a New Crisis, by W. I. Ladejinsky (pp. 515-534).

**Classification of agricultural areas, Frederick County, Maryland, R. W. HARRISON and P. L. SEARFOSS.** (Coop. U. S. D. A.). (*Maryland Sta. Bul. 440* (1941), pp. 225-266, figs. 10).—The main objective of the study was "to develop a method of land classification which can be used efficiently and expediently under the wide range of conditions which characterize the agriculture of the State of Maryland." Information included in about 200 farm schedules obtained in 1939 in Frederick County, information on Farm Credit Administration schedules for about 2,500 farms in the county, and land classification maps previously prepared by the County Land Use Planning Committee, and the Farm Credit Administration Maps are presented and discussed, showing for the county climatic data, topography and erosion, soil characteristics, soil productivity ratings, types of farm land use, agricultural production, gross farm income, size and condition of buildings, and social conditions. Of these nine factors the following were found to be of the most practical value for classification of agricultural lands: Topography and erosion; soil productivity ratings; percentage of land in crops; agricultural production (indexes of crop yields and numbers of livestock); condition of buildings; gross farm income; and assessed values (as an index of social conditions). "Data representing each of the seven factors mentioned above were plotted on individual maps having a scale of 1 in. to 1 mile. Area of homogeneous characteristics were delimited on the several maps. In order that every part of the county might be systematically covered in the final appraisal, an outline map of the same scale as the several factor maps was ruled into 1-in. squares. By placing this outline map over the separate factor maps, the detailed characteristics of each 1-in. unit of area were entered in code by the use of the weighting system shown in [a table]. The weights in this table and the class intervals derived therefrom are the result of numerous statistical studies of the interrelation of factors. Some of these relationships are shown in table and map form in this bulletin. The limitations of space prevented a complete presentation of all of the statistical data."

Five classes of agricultural land in the county, in addition to nonagricultural and residential areas, are delimited and are described and mapped.

**The appraisal of farm buildings, J. C. WOOLEY and R. P. BEASLEY** (*Missouri Sta. Cir. 213* (1941), pp. 10, fig. 1).—Tables and a chart are included, showing the classification of buildings, constants for use in determining cost per cubic foot of different types of buildings, depreciation rates for farm buildings, soil-productivity classification for Missouri, acres of pasture and crops on different classes of land required to support one animal, and building-space requirements for different animals. The use of these data in determining structural value, place or use value, and appraised value are discussed and illustrated.

**A study of farm organization by type of farm in Sanpete and Sevier Counties, W. P. THOMAS, G. T. BLANCH, and E. HAYBALL** (*Utah Sta. Bul. 300* (1941), pp. 75, figs. 5).—This study is one of the series (E. S. R., 77, p. 553) "designed to furnish a general description and a detailed analysis of the type of farming in various parts of Utah." Part I is a general description of Sanpete and Sevier Counties and their agricultural resources, in which the number, size, and types of farms, the transportation and marketing facilities, landownership and use, crop acreages and yields, numbers of livestock, etc., are discussed.

Part II is based upon farm business records for 1936 for 270 farms in the two counties. In the first section an analysis is made of the records for 187 general irrigated farms classified on a county basis. In the second section analysis is made of the 270 records to compare the 5 major types of farming and to ascertain the factors affecting the success of each type. The 270 farms included 187 general irrigated farms, 28 beef cattle ranches, 32 sheep ranches, 10 lamb-feeding enterprises, and 13 part-time farms. The labor income on general irrigated farms averaged \$172 for Sanpete County and \$303 for Sevier County, and in addition the operators had farm privileges valued at \$285 in Sanpete County and \$332 in Sevier County. For the two counties, the average labor incomes on the different types of farms were: General irrigated farms, \$222; beef cattle ranches, —\$180; sheep ranches, \$1,697; lamb-feeding, \$508; and part-time farms, —\$87. Some of the findings were: "On general irrigated farms, there was a positive relationship between size of farm business, labor efficiency, crop yields, and labor income. . . . On the beef cattle farms studied, there was no significant relationship between size of unit and labor income. A negative relationship between number of beef cattle per farm and labor income was found. . . . A consistent relationship was shown between labor income and crop yields. The labor income for the group of farms with crop index of more than 125 averaged \$172, as compared to a labor income of —\$470 for farms with a crop index of less than 75."

For the sheep ranches an operating unit of 1,096 productive man-work-units was favorable to economic production. For the part-time farms, the factors affecting profits were: Small size of farm business, low labor efficiency, and low rates of production.

**Farm business summary, Michigan, 1940, C. O. MAY and J. C. DONETH** (*Michigan Sta. Quart. Bul., 24* (1941), No. 2, pp. 132-144, figs. 3).—Farm account records for 1940 for 1,203 farms are summarized in tables showing by items the average capital investment, receipts, and expenses. Charts show the number and percentage of farms in different labor income groups and the relationship between the ratio of Michigan farm prices to farm costs and labor income, 1929-40. Other tables compare the financial returns on Michigan farm-account farms for the years 1929-40, inclusive; present the financial summary of the 1940 farms by type-of-farming areas; and give data for 1940 by type-of-farming areas as to kinds, acreage, yields, etc., of crops; kinds, amounts, and returns from livestock; and expenses and efficiency factors (labor, machinery, improvement, and other costs).

**An economic study of the organization and management of beef cattle and other types of farms in Russell County, J. J. VERNON.** (Coop. U. S. D. A.). (*Virginia Sta. Tech. Bul. 71 (1941), pp. 186, figs. 10*).—Analysis is made of records for the year ended September 30, 1935, obtained by the survey method for 226 beef and 272 nonbeef farms in Russell County. Records were not obtained for farms of less than 10 acres of crops unless some beef cattle were kept. The problems, the regional conditions, the economic conditions in 1934-35, and the agricultural development in the area are discussed. Analysis is made of the effects of size of business, productive efficiency, labor efficiency, capital efficiency, and the balance of these factors on the variations in the returns from the farm business. Analysis is also made of the factors affecting the costs and returns from the beef cattle enterprise and the cost of producing calves and raising replacement cows. The data and the analyses are presented in 132 tables and 8 charts, and are discussed in considerable detail.

**Management practices with large lima beans in southern California, W. SULLIVAN, W. M. CORY, and M. D. MILLER** (*California Sta. Bul. 657 (1941), pp. 30, fig. 1*).—This is an analysis and summarization of 161 records obtained during the period 1932-39 in enterprise-efficiency studies conducted by the Agricultural Extension Service of the University of California in Ventura and Orange Counties. Eighty-six records cover land operated by tenants and 75 land operated by owners. Irrigation costs were reported on 113 records. The production of large and baby lima beans, the factors limiting production, marketing, prices, etc., are discussed. The principal part of the report consists of tables with discussion giving (1) a general summary of yields, income, and costs by years 1932-39, in which the yield and income are separated into cleaned beans, cull beans, and bean straw, and the costs are grouped into the major items of cultural and harvest labor and field power, material used, cash overhead, depreciation, and interest on investment or rent; and (2) more detailed tables showing by years the average cost per acre of man labor and field power for land preparation, planting, cultivating, and harvesting, for materials and supplies, for overhead costs, and for capital investment, interest, and depreciation. Other tables show rental costs and the monthly prices, September 1920 to August 1940, of large lima and baby lima beans, f. o. b. California. A standard of inputs of labor, materials, and costs under specified conditions on a typical owner-operated, 100-acre irrigated farm having better-than-average management is presented.

**Economic aspects of the distilling industry in Maryland, S. H. DELVAULT, W. P. WALKER, and R. W. HARRISON** (*Maryland Sta. Bul. A3 (1941), pp. [4]+73-89+2, figs. 7*).—The data for this study made in 1940 were obtained by personal interviews with distillers and questionnaires sent companies whose main offices were outside the State. Facts are included as to number of persons employed, total wages and salaries, investment, materials used, the relation of distilling to other industries, stocks and production of the distilling industry of the State, public revenues from distilled spirits, and similar subjects.

The distilling industry in Maryland had a capital investment of over \$37,000,000, employed about 1,727 persons, and paid about \$2,300,000 in wages. About \$7,633,000 is spent annually for supplies, of which \$2,273,000 is for grain. The production of raw spirits amounted to 11,862,632 proof gallons during the year studied. The industry paid taxes, or assumed obligation for taxes, amounting to over \$30,000,000 during the year.

**Efficiency in the use of farm machinery in Arizona, N. O. THOMPSON** (*Arizona Sta. Bul. 174 (1941), pp. [4]+257-278, figs. 4*).—This bulletin is based on an analysis of (1) detailed machinery cost and operating records for 34 farms

in the eastern part of the Salt River Valley for 1 yr. beginning in the fall of 1939, and (2) a survey of machinery investment and practices followed in other parts of the Salt River Valley, Casa Grande Valley, and the Yuma area. The 24 farms for which records were obtained were mostly diversified 30- to 600-acre farms on which the major crops were cotton and alfalfa. Forty-three tractors ranging from 9.8 to 26.8 drawbar hp. were owned by the farmers. Analysis is made of the tractor cost per hour of operation and the machinery and labor cost for plowing, floating, disking, bedding, and planting row crops, cultivation, stalk cutting, bordering, harrowing, renovating, seeding small grains, hay making, etc., and these costs are compared with the prices charged by contractors. Analysis of machinery investment on irrigated farms and suggestions for the machinery for typical types of irrigated farms are made.

The average costs per hour for operating general-purpose tractors were: 9.8-13 hp., 2-row, 64 ct.; 15.5-16.9 hp. (mostly 4-row) 85 ct.; and 18.1-26.8 hp., \$1.17.

"Cost comparisons indicated that ordinarily it was to the farmers' advantage to contract their plowing, subsoiling, and renovating to custom operators. In many instances where the land was custom-plowed it was necessary to hire the land floated as well because of its rough uneven condition. Other tillage operations of disking, cultivating, bordering, bedding, and harrowing were usually performed cheaper by the farmer using his own equipment. Such operations as stalk cutting, planting of row crops, and drilling of small grains—operations requiring machinery that is used only a few days each year—were cheaper to contract when the acreage involved was small, unless such machinery was rented or owned jointly with a neighbor. The farmer's decision on whether or not to contract his mowing and raking of hay or own the necessary equipment seemed to depend more on the relative importance of alfalfa in the cropping system than on the size of the acreage involved.

"The average machinery investment per crop acre for different sized farms was as follows: Less than 80 crop acres, \$20.53; 80-150 crop acres, \$15.02; 160-239 crop acres, \$10.02; 240-319 crop acres, \$10.19; 320 and more crop acres, \$7.82. From this it was evident that farms of less than 160 crop acres tend to operate at a machinery-cost disadvantage."

**Quality-price relationships of cotton at local markets in Oklahoma.** T. R. HEDGES (*Oklahoma Sta. Bul. 250 (1941), pp. 35, figs. 8*).—This investigation has revealed that a policy of paying producers a set price for all grades of cotton, rather than varying prices for individual bales of cotton according to their quality, is detrimental both to the cotton grower and to the cotton industry. It either penalizes producers of premium cotton, subsidizes producers of low-quality cotton, or does both, thereby encouraging producers to increase the proportion of low-quality cotton in the total crop; makes it harder and harder to find a market for Oklahoma cotton; and forces the ginner to offset the losses incurred through transactions in cotton with earnings from other departments of their businesses and thereby produces an artificial market for cotton.

**Cooperative grain elevators in North Dakota and eastern Montana.** H. E. RATCHFEE, P. V. HEMPHILL, and H. F. HOLLANDS. (*Coop. N. Dak. Agr. Col. and Mont. State Col.*). (*U. S. Dept. Agr., Farm Credit Admin., Coop. Res. and Serv. Div., Bul. 43 (1941), pp. VI+58, figs. 22*).—The authors found that the number of member-patrons was closely related to volume of grain handled. Membership may be enlarged by selling shares of capital stock with a low par value. Current assets averaged 1.6 times current liabilities for the eastern area compared with 2.6 for the western area. The amount of side line sales in the eastern area showed no appreciable change during the 3-yr. period 1935-36 to 1937-38, while in the

western area such sales increased considerably and were larger and of greater importance in influencing operating results. Side lines in the eastern area included coal, twine, feed, flour, lumber, seeds, and petroleum. Cooperative elevators in the area studied required a minimum annual grain volume of approximately 100,000 bu. to meet operating expenses, provide for necessary services for patrons, and protect their capital structure. When grain volume was not that large, a total business volume of more than \$100,000 annually was needed. Even large business volume does not assure net savings unless unit costs are kept to minimum. Other factors influencing elevator operation were efficiency in the use of labor and extent to which the elevator facilities were used.

**Budgeting in Texas counties, 1931-1940, H. C. BRADSHAW** (*Texas Sta. Bul. 603 (1941), pp. 33, figs. 3*).—"The purpose of this study is to examine the results which have been obtained by Texas counties under the uniform budget law passed in 1931." A sample including 60 of the 254 counties of the State was studied for the calendar year 1935. Schedules were also obtained for 26 of the same counties for the calendar year 1939. Information was obtained from the official copies of budgets filed with the State comptroller, from field audits made by the Highway Planning Survey, and interviews with county officials. The provisions of the law, the budget form, and the compliance with the law are discussed. The budgeted or estimated receipts and disbursements in 51 of the 60 counties that filed budgets are compared and discussed. Sections are devoted to the discussion of the content and arrangement of budgets and the essentials of a good county budget.

During the 6-yr. period 1935-40, an average of 207 or 82 percent of the counties of the State filed budgets annually. One group of 139 counties filed a budget each year and 11 counties filed no budgets during the period. Of the 231 funds in the 60 counties studied in 1935 the expenditures were less than the income for 83.1 percent of the funds. For the 100 funds in the 26 counties studied in 1939 the percentage was 92 as compared with 84 for the same counties in 1935.

## RURAL SOCIOLOGY

[Investigations in rural sociology by the Colorado Station, 1941] (*Colorado Sta. Rpt. 1941, pp. 47-48*).—The following topics are briefly discussed: Some health practices and attitudes and related problems, farm population and farm population movements, youth problems, and beet labor problems.

**The transmission of farming as an occupation, W. A. ANDERSON** ([*New York: Cornell Sta. Bul. 768 (1941), pp. 29, figs. 4*]).—Important conclusions, based on three samples from the farming and nonfarming populations of New York State, were that farming as an occupation is transmitted from fathers to sons to a greater extent than are nonfarming occupations. Farming is self-perpetuating, being carried on from generation to generation chiefly by sons already engaged in it. This occupation is inherited most commonly by the oldest son in the family. There is no evidence that farmers' sons are less successful in entering positions of equal rank with nonfarmers' sons.

**Farmers study their communities in Hand County, South Dakota, R. L. McNAMARA.** (Coop. So. Dak. Expt. Sta. et al.). (*U.S. Dept. Agr., Bur. Agr. Econ., 1941, pp. [31]-27, figs. 8*).—The primary purpose of this report was to outline a procedure whereby farm people in a given county may study and delineate the neighborhoods and communities in their own areas. The task of community study was worked out by the farmers themselves. Among the matters studied were population changes, service and nationality areas, schools, and churches. The results are presented by maps and tables and discussed in considerable detail.

**Neighborhoods and communities in Covington County, Mississippi,** H. HOFFSOMMER and H. PRYOR (*U. S. Dept. Agr., Bur. Agr. Econ., 1941, pp. [1]+31, figs. 9*).—While this study revealed that the boundaries of the communities, and in some instances even the location of the centers in this cut-over pine sections, had changed, it was found that neighborhoods and communities remained and that those of today are the descendants of these earlier stages of development. By noting these trends it was possible to forecast in some measure developments that will occur in the future in enabling farm people to make plans accordingly.

**Culture of a contemporary rural community, El Cerrito, New Mexico,** O. LEONARD and C. P. LOOMIS (*U. S. Dept. Agr., Bur. Agr. Econ., Rural Life Studies No. 1 (1941), pp. [IV]+72, figs. 20*).—This is the first of six analyses of the factors affecting community stability and instability by the participant observer method.

"The village of El Cerrito is a singular example of a group of people that has maintained its individuality in the face of the ever-increasing forces that have been brought to bear upon it. Not only has it failed to keep in step with modern technological progress but it has managed to exist in its own way after the greater part of its economic base had been lost. In this respect, as well as in many others, it is highly representative of a large number of other native villages that lie in the area of the Pecos watershed. Definitely submarginal to date in its capacity to support the present population, it is highly integrated and unified socially, functioning in many instances as a single unit."

**Cut-over lands of western Washington: A study of settlement experience and opportunities,** C. P. HEISIG. (Coop. Wash. Expt. Sta.). (*U. S. Dept. Agr., Bur. Agr. Econ., Migration and Settlement Pacific Coast Rpt. 6 (1941), pp. [2]+68, figs. 10*).—More than one-half of the 1,051 families living in the five local areas studied had taken over their farms after 1929. About one-half of these settlers were from the State of Washington, while slightly less than one-half of those from outside of Washington, or 22 percent of all new settlers, came from the Great Plains. Discussion included size of farm, farm income, source of funds used in family living, living conditions, land clearing, alternative methods of rendering settlers assistance, the importance of land selection, and probable needs for development.

**New settlers in Yakima Valley, Washington,** C. F. REUSS and L. H. FISHER. (Coop. Wash. Expt. Sta.). (*U. S. Dept. Agr., Bur. Agr. Econ., Migration and Settlement Pacific Coast Rpt. 8 (1941), pp. [3]+47, figs. 8*).—Substantially identical with Washington Station Bul. 397 (*E. S. R.*, 86, p. 118).

**Building rural communities** (*Amer. Country Life Conf. Proc., 23 (1940), pp. [4]+171*).—The following papers were presented at La Fayette, Ind., November 6-9, 1940: *Rural People and World Peace*, by H. C. Taylor (pp. 22-31); *The Rural Community's Role in Program Planning*, by N. T. Frame (pp. 32-37); *Organizing Community Meetings*, by D. E. Lindstrom (pp. 38-40) (*Univ. Ill.*); *Rural Schools Are Awakening to Community Needs*, by I. E. Schatzmann (pp. 41-43); *The Rural School and the Rural Community*, by F. Martin (pp. 44-47); *Community Education—A Challenge to All*, by H. Mittelholtz (pp. 48-54); *Shepherds' Pipes at Olive Branch*, by C. Meyer (pp. 55-58); *Helping Girls To Help Themselves*, by M. L. Jesse (pp. 59-60); *Activities Relative to Rural Environment as Carried on at the State Teachers College, Mayville, North Dakota*, by E. V. Johnson (pp. 61-62); *Parke County's Correlated Program*, by G. Alexander (pp. 63-68); *Rural Community High Schools*, by V. H. Sorenson (pp. 69-76) (*Univ. Wis.*); *A Rural Community and Its School Resources*, by

M. L. Smith (pp. 77-84); The Importance of Books in Rural Communities, by J. W. Merrill (pp. 85-86); American Music and Folk Dances, by S. A. Anderson (pp. 87-90); Expressions of Rural Art, by E. E. Andrew (pp. 150-158); and The Negro's Contribution to American Folk Songs, by C. Elliott (pp. 159-160).

**The challenge to democracy.—VI, Toward a new rural statesmanship,** E. D. Ross (*Iowa Sta. Bul. P26, n. ser. (1941), pp. 701-716*).—This discussion of rural leadership is the sixth of a series on democracy.

**County government in Washington,** C. F. REUSS (*Washington Sta. Bul. 400 (1941), pp. 62, figs. 10*).—This is the third of a series on rural social institutions (E. S. R., 81, p. 589; 84, p. 411). It deals with the services performed, backgrounds of Washington counties, the administrative personnel, an analysis of financial operations, and suggestions for the reconstruction of county government in the State.

**A descriptive study of the rural and small city relief population in Oklahoma,** T. G. STANDING (*Oklahoma Sta. Bul. 251 (1941), pp. 23*).—Information is presented descriptive of the relief population in comparison with the general population in the nine counties included in this study.

"Aside from emphasizing the magnitude of relief needs in rural areas, one of the most outstanding facts which emerges from this study is the essential similarity of the relief population to the general or total population. It is true that relief families are slightly larger and that the relief group as a whole is somewhat younger and less well educated than the general population. But when these and other possible differences are taken into account, the fact remains that a major proportion of all persons receiving relief are indistinguishable from the rest of the population except in regard to economic status."

**Virginia's marginal population: A study in rural poverty,** W. E. GARNETT and A. D. EDWARDS (*Virginia Sta. Bul. 335 (1941), pp. 166, figs. 54*).—The authors conclude that around 100,000 white families or between one-third and one-half of the white rural population and a still larger proportion of the Negroes, even in normal times, may be classed as marginal. The 1930 census data showed that 35,752 or 38 percent of the white farm owners, 19,291 or 65 percent of the white tenants, 16,628 or 69 percent of Negro owners, and 9,734 or 69 percent of Negro tenants had gross incomes of less than \$800. The authors discuss the extent, composition, and location of the marginal population and factors contributing to marginality, including background, economic and social, institutional, and biological factors. A number of family case histories are presented. A disproportionate increase of the marginal standard population is also shown. Corrective measures are suggested.

**The pecan shellers of San Antonio,** S. C. MENEFEE and O. C. CASSMORE (*Washington: Fed. Works Agency, Work Proj. Admin., Div. Res., 1940, pp. XIX+82*,

[*pls. 5*, *figs. 3*].—This report presents the problem of underpaid and unemployed Mexican labor in the pecan shelling industry in San Antonio, Tex.

Station project reveals clue to "unknown quantity" in improving health for defense, R. W. ROSKELLEY and B. YOUNG (*Colo. Farm Bul. [Colorado Sta.]*, 3 (1941), No. 4, pp. 5-6).—The authors found that "a relatively large proportion of the population considered does not follow certain recommended practices of dental hygiene and sanitary measures which have been defined as essential for healthful living. . . . In general, with but slight variation, children follow the pattern of their parents with respect to both dental and dietary practices. . . . The possession of a garden seemed to have a definite influence on the frequency with which certain vegetables were eaten in the summer months but not in the winter months." The importance of educating the homemaker as a means of improving health practices in families is emphasized.

[*Virginia rural youth survey*] (*Virginia Sta., Rural Sociol. Rpts. 13* (1940), pp. [23], *figs. 2*; 14 (1940), pp. [6]+64, *pls. 4*, *figs. 14*; 15 (1940), pp. [6]+28, *figs. 4*; 16 (1941), pp. [74], *figs. 9*; 17 (1941), pp. [59], *figs. 8*; 18 (1941), pp. [32]; 19 (1941), pp. [17], *figs. 7*).—These reports give information on the following subjects: No. 13, The Virginia Rural Youth Survey: A Progress Report and Related Questions, by W. E. Garnett and A. D. Edwards; No. 14, Youth in a Rural-Industrial Situation, Spencer-Penn Community, Henry County, Virginia, by A. D. Edwards; No. 15, Negro Youth in a Colton-Peanut County, Southampton County, Virginia, by S. J. Harris; No. 16, Youth Adjustments in a Rural Culture, Rockville Community, Hanover County, Virginia, by D. G. Jones; No. 17, Preliminary Findings of the Virginia Rural Youth Survey, by C. G. Burr and W. E. Garnett; No. 18, Discussion Guide for Youth Groups—Preliminary, by M. McD. Ward, C. G. Burr, and W. E. Garnett; and Conditions and Trends Calling for the Concerted Attention of All Forward Looking Citizens, by W. E. Garnett, A. D. Edwards, W. H. Roney, et al.

## AGRICULTURAL AND HOME ECONOMICS EDUCATION

Life science, M. W. DE LAUBENFELS (*Author*, [1941], pp. [IV]+320, *figs. 1,022*).—"This book is intended for the general reader as well as a text for college students. It covers the material that the ordinary American citizen needs, as worked out by careful research during 11 yr., with the cooperation of nearly 3,000 students." Following the introductory material, the section headings are what is life? or the story of protoplasm; man, the representative; health for home and neighborhood; the natural history of vegetables; the natural history of animals; heredity and environment; and life through the ages.

Showmanship in the classroom, L. F. PAYNE. (*Kans. State Col.*). (*Poultry Sci.*, 21 (1942), No. 1, pp. 94-96).—A discussion is presented of teaching methods that have proved successful in the poultry classroom.

The market-milk industry, C. L. ROADHOUSE and J. L. HENDERSON (*New York and London: McGraw-Hill Book Co.*, 1941, pp. XV+624, *figs. 167*).—This text is planned for college students who have had some instruction or experience in dairying or the dairy industry. The several chapters deal with the history and development of the market-milk industry; the composition of milk and its physical and chemical properties; micro-organisms, enzymes, and cells of milk and cream; milk and the public health; safeguarding the milk supply; sanitary production of market milk; construction and arrangement of sanitary dairy-farm buildings; country milk-receiving stations; the transportation of milk; flavors of milk; construction and arrangement of the city milk plant; milk-plant operation; washing and sterilizing dairy equipment; pasteurization

of milk; mechanical refrigeration; the cooling of milk; the creaming of milk; table cream and whipping cream; special milk products; the distribution of milk; the cost of milk production; the price of milk and price plans; dairy inspection and market-milk control; the use of milk in nutrition; and the milk-plant laboratory and its operation. Each chapter is followed by references. Appendixes include problems in standardization of milk and cream, a table for use in computing logarithmic averages of bacterial counts, a table showing the International Association of Milk Dealers' depreciation rates of milk plants and equipment, and the U. S. Public Health Service milk ordinance.

**The new home economics omnibus**, F. L. HARRIS and H. II. HUSTON (*Boston: Little, Brown & Co., 1941, pp. XV+666, [pls. 25], figs. [275]*).—A revision of a previously noted text (E. S. R., 77, p. 127).

## FOODS—HUMAN NUTRITION

**Foods and nutrition** [at the Bureau of Home Economics] (*U. S. Dept. Agr., Bur. Home Econ. Rpt., 1941, pp. 7-13*).—This annual report (E. S. R., 84, p. 836) summarizes the work of the Foods and Nutrition Division on vitamin A in nutrition, vitamin content of foods, and food selection and preparation.

**[Nutrition studies by the Alabama Station]** (*Alabama Sta. Rpt. 1940, pp. 23-25*).—Progress reports (E. S. R., 81, p. 140) are given on studies by W. D. Salmon on the relation of pyridoxin, pantothenic acid, and linoleic acid to the cure of rat acrodynia; by R. W. Engel on choline deficiency in young rats (E. S. R., 86, p. 420); by Engel on effect of calcium pantothenate and other B-vitamin factors on liver fat; and by W. C. Sherman on the comparative nutritive value of the protein of cowpeas and soybeans.

**[Studies on food preparation and utilization at the Colorado Station]** (*Colorado Sta. Rpt. 1941, pp. 26-29*).—This progress report (E. S. R., 84, p. 692) summarizes work previously noted and findings on the relative juice yield from cherries of U. S. No. 1 grade and slightly smaller fruits.

**Symposium on "food resources of Hawaii"** (*Pan-Pacific, 4 (1940), No. 4, pp. 3-12, figs. 4*).—This symposium, held under the auspices of the Hawaiian Academy of Science at its sixteenth annual meeting, included an introduction by A. L. Dean and the following papers: Hawaii's Food Supply, by H. H. Warner (pp. 4-5) (Univ. Hawaii); and Hawaii's Food Requirements Under Normal and Emergency Conditions, by M. Potgieter and C. D. Miller (pp. 6-9), and Beef and Dairy Resources in Hawaii, by L. A. Henke (pp. 10-12) (both Hawaii Expt. Sta.).

**The analysis of Ceylon foodstuffs.—IX, A, The composition of some Ceylon honeys; B, The nutritive value of some palmyra products**, A. W. R. JOACHIM and S. KANDIAH (*Trop. Agr. [Ceylon], 95 (1940), No. 6, pp. 339-343*).—These two studies are in continuation of the series noted earlier (E. S. R., 85, p. 570). The five honeys are described and data are reported for their content of moisture, sugars (total, sucrose, glucose, and fructose), and dextrin, and their acidity. Analytical data are presented for products of the palmyra palm, including the dried roots (raw and parboiled), palmyra jaggery, the dried fruit pulp, and the sweet and fermented palmyra sap.

**Foods and drugs**, E. R. TOBEY (*Maine Sta. Off. Insp. 179 (1941), pp. 131-261*).—This annual report (E. S. R., 84, p. 694) gives the results of analyses of official samples of foods and drugs. Data are reported on the caffeine content of coffee, tea, cocoa (all as beverages), chocolate sirup, and beverages of the cola type; on specific gravity, butterfat, solids-not-fat, total solids, sediment, and plate count of a great number of samples of milk; on butterfat and grade of many samples of cream; on free fatty acid, color, and results of cold test in pack-

ing oils for sardines; and on free liquid, and solids in the drained meats, of clams. Results of bacteriological examinations of utensils and results of analyses of a number of drugs are also reported.

**Selenium in wheat and wheat products**, H. W. LAKIN and H. G. BYERS. (U. S. D. A.). (*Cereal Chem.*, 18 (1941), No. 1, pp. 73-78).—This paper presents a résumé of the results of determinations of the selenium content of 951 samples of wheat and wheat products collected in portions of Colorado, Kansas, Nebraska, South Dakota, Wyoming, Montana, North Dakota, and Minnesota. The places of collection were in seleniferous areas, or in towns that might handle grain from such areas. Of these samples, 82.5 percent contained 1 p. p. m. or less, 10 percent contained 2-3 p. p. m., and 7.5 percent contained 4 p. p. m. or more of selenium. Only 8 samples contained as much as 10 p. p. m. or more. It is pointed out that little information is available as to the toxic limits for humans, but that there is evidence (E. S. R., 76, p. 375) that 4 p. p. m. would be toxic to animals if fed as the sole diet. Since the wheat from the areas examined constitutes but a minor portion of the wheat production of the States involved, since only 7.5 percent of the samples contained enough selenium to be toxic to white rats when fed as the sole diet, and since seleniferous wheat is greatly diluted when shipped to large milling centers, it is considered that seleniferous wheat probably constitutes no health hazard to people outside the seleniferous area. Selenium was found in all samples analyzed in the present study, as well as in all examined by W. O. Robinson.<sup>3</sup> It is considered, therefore, that "the mere presence of selenium in wheat must not be viewed with alarm, since it is probably a normal constituent and becomes a problem only when it occurs in sufficient quantities to be injurious."

**Note on the use of yeast to destroy glutathione in wheat-germ for bread-making**, E. W. HULLETT (*New Zeal. Jour. Sci. and Technol.*, 22 (1940), No. 1B, pp. 44B-47B, figs. 2).—The adverse effects on dough and bread quality associated with the use of untreated wheat germ are avoided by preparing a "ferment" of the germ, yeast, and water and allowing this to stand for a number of hours, during which time fermentation takes place and the glutathione disappears. After the required time the ferment is mixed with flour, salt, sugar, and more water and made into a dough from which bread is made in the ordinary manner. Four percent of the treated germ (on a flour basis) gives a bread very similar to ordinary white bread. With 10 percent of germ, the crumb texture and volume are only slightly affected, but the crumb color is light brown. Biological tests indicate that vitamin B<sub>1</sub> survives the process. High extraction flour treated like the wheat germ gives satisfactory results in a process involving the use of 16 gm. of the low-grade flour and 2.5 gm. of yeast in the sponge which is allowed to stand for 3 hr.; 109 gm. of 70-percent extraction flour and the usual amount of sugar are then added to the ferment and the resulting dough fermented for a further 3 hr. and then baked. The loaf has a somewhat grayish crumb color, but in other respects is not seriously inferior to a loaf made from a 70-percent extraction flour by a straight-dough process. The success of the method suggests that glutathione elimination may be an important part of the dough-ripening process. Practically, the method affords a means of raising the vitamin B<sub>1</sub> content of bread.

**The addition of homogenized vegetables to the diet of the young infant**, M. L. BLATT, H. M. JACOBS, J. B. MURPHY, and M. ZELDES (*Arch. Ped.*, 58 (1941), No. 1, pp. 40-47, figs. 4).—On the thesis that a broad iron-containing diet seems indicated as a routine in infant feeding to supplement the iron deficiency of milk, a study was made of the response of infants from 1 to 6 mo. of age to

<sup>3</sup> *Indus. and Engin. Chem.*, 28 (1936), No. 6, pp. 736-738, fig. 1.

the addition of a homogenized vegetable mixture to the basic formula. This mixture upon analysis showed an average of 31 mg. of calcium, 54 of phosphorus, 1.58 of iron, and 0.15 mg. of copper per 100 gm. Sixty-four infants, 23 of whom were observed for 4 mo., were started with 1 or 2 teaspoonfuls of the homogenized vegetables. Those started at from 5 to 6 mo. were given 1 tablespoonful. The amounts were increased by 1 or 2 teaspoonfuls every second week until 3 or 4 tablespoonfuls were being given. Hemoglobin curves paralleled the normal in contour except that the lowest drop in hemoglobin came between the eighteenth and twenty-fourth weeks rather than at the twelfth week as is normal. From this point the trend was upward, surpassing the normal average within a few weeks. The erythrocyte curves also paralleled the normal, although the counts were lower than normal values. The birth weight was doubled at  $4\frac{1}{2}$  mo. in the group started on the homogenized vegetables at from 1 to 2 mo. and at  $4\frac{3}{4}$  mo. in the group started at from 2 to 3 mo. The height increase was correspondingly rapid, the vegetables were well tolerated, produced no diarrhea, and were apparently well digested, since few vegetable fibers were seen in the stools and those only after prolonged and diligent search.

**Polyphenolase activity as a primary cause in darkening of boiled potatoes.** W. E. TOTTINGHAM and C. O. CLAGETT. (Wis. Expt. Sta.). (*Science*, 94 (1941), No. 2477, p. 497).—Following the finding that a compound reacting like catechol was associated with the blackening of potatoes after boiling (E. S. R., 85, p. 692), the polyphenolase system was investigated and found to be associated with the blackening tendency.

**Composition of fireweed honey.** J. A. ELLEGOOD and L. FISCHER (*Food Res.*, 5 (1940), No. 6, pp. 559–561).—Four samples of fireweed (*Epilobium angustifolium*) honey, obtained from the State of Washington, are described as to origin, and results of analyses by A. O. A. C. methods are presented. Direct and indirect polarization at 20° and 87° C., water, invert sugar, sucrose, ash, dextrin, and free acid as formic are reported.

**Fruit products which the farmer can make.** D. K. TRESSLER (*Farm Res.*, [New York State Sta.], 8 (1942), No. 1, pp. 13, 14, 15).—This article indicates briefly the possibilities of some of the more important fruit products, and outlines the general nature of their manufacture. For details as to the preparation of frozen fruits, fruit juices, glace fruits, and other fruit products, the reader is referred to station and other publications, most of which have been noted previously (E. S. R., 76, p. 297; 79, pp. 563, 583; 81, p. 449; 83, p. 701).

**Dried citrus fruits for marmalade.** W. V. CREUSS and J. SUGIHARA. (Univ. Calif.). (*Canner*, 94 (1941), No. 4, pp. 11–12, fig. 1).—Sliced citrus fruits were successfully dried to give a product satisfactory for making marmalade. In the case of oranges the lightly sulfured fruit gave the more satisfactory product from the standpoint of color, and the flavor of the fruit was not adversely affected. For each pound of dried product, 6.7, 6.5, and 4.7 lb. of raw sliced grapefruit, lemon, and orange, respectively, were required. Each pound of dried fruit, used in the proportion of 30 parts of orange, 10 of lemon, and 10 of grapefruit by weight, yielded 19 and 13 lb., respectively, of the pulpy and golden shred types of commercial marmalade.

**Nutritive properties of steam-rendered lard and hydrogenated cottonseed oil.** R. HOAGLAND and G. G. SNIDER. (U. S. D. A.). (*Jour. Nutr.*, 22 (1941), No. 1, pp. 65–76).—The results of the present experiments, confirming those of a previous study (E. S. R., 83, p. 269), indicated that steam-rendered lard and hydrogenated cottonseed oil had about the same growth-promoting value for rats when fed at 5-percent levels, but that lard was somewhat supe-

rior at higher levels. "Both lard and hydrogenated cottonseed oil induced maximum growth when the diets contained 30 percent, and minimum growth when the diets contained 5 percent, of fat. Each fat was utilized least efficiently for growth when the diet contained 5 percent of fat, but each was utilized with approximately equal efficiency whether the diet contained 15, 30, or 54 percent of fat. Lard was superior in digestibility to hydrogenated cottonseed oil at each level of fat intake. The digestive coefficients for lard ranged from 95.9 to 97.4 percent with an average of 96.4 percent, whereas those for hydrogenated cottonseed oil ranged from 91.0 to 95 percent with an average of 92.9 percent."

**Wrapping meat for frozen storage**, L. H. BLAKESLEE (*Michigan Sta. Quart. Bul.*, 24 (1941), No. 2, pp. 111-113, fig. 1).—This brief discussion concerning satisfactory materials and methods for wrapping meat for frozen storage is based upon studies in part noted earlier (E. S. R., 83, p. 560).

**Mechanisms of biological oxidations**, D. E. GREEN (*Cambridge, Eng.: Univ. Press*, 1940, pp. [7]-181, figs. 22).—This book deals first with the general properties of oxidation enzymes and then considers the nature and mechanism of action of specific enzymes acting as catalysts in intracellular oxidation reactions. The several chapters deal with Fe porphyrin protein enzymes, pyridino-protein enzymes, flavoprotein enzymes, Cu protein enzymes (with an addendum on a Zn protein enzyme), thiaminoprotein enzymes, cytochrome-reducing dehydrogenases, unclassified oxidation enzymes, and oxidations in organized systems.

**The growth curve of the albino rat in relation to diet**, T. F. ZUCKER, L. HALL, M. YOUNG, and L. ZUCKER (*Jour. Nutr.*, 22 (1941), No. 2, pp. 123-138, figs. 4).—Data on the mean weights at successive age intervals of male and female rats in the breeding colonies of several laboratories (including the authors') were analyzed to answer the question "What is normal or optimal growth or what should be the course of growth in the rat strain employed, when there are no deficiencies?" The analyses showed that rats on present-day stock diets grow at a progressively decreasing rate after weaning. Growth curves, with the point of inflection in the preweaning period and with a constantly decreasing slope in the postweaning period, are greatly simplified as compared with those based on early data and seem to justify the attempt to convert them to a straight-line function of time and weight. In the equation developed the logarithm of the weight is plotted against the reciprocal of the time, according

to the formula  $\log W = \frac{-k}{t} + \log A$ , where  $W$  is the weight at time  $t$ ,  $A$  is the weight approached asymptotically in the adult animal, and  $k$  is the slope of the line which characterizes the rate of growth  $\left(k = \frac{\log W_2 - \log W_1}{1/t_2 - 1/t_1}\right)$ .

"Neither natural variation in size of the animal nor artificial stimulation of growth rate causes a deviation from the empirical formula of growth. While inherent size of rats varies considerably, the slope of the plot ( $k$  of the formula) varies but little for each sex in albino rats. In all cases where data for males and females are available, the ratio of  $k$  for males and  $k$  for females is constant within 3 percent. Deviations on diets suboptimal for growth are discussed."

**Growth and calcification on a diet deficient in phosphate but otherwise adequate**, T. F. ZUCKER, L. HALL, and M. YOUNG (*Jour. Nutr.*, 22 (1941), No. 2, pp. 139-151, figs. 4).—A rachitogenic diet, No. 803, composed of starch 65 percent, cottonseed flour 20, casein 6, egg albumen 3, NaCl 1, cottonseed oil containing carotene 2 (furnishing 750 units of vitamin A per 100 gm. of diet), and CaCO<sub>3</sub> 3 percent, was found to be comparable to the rachitogenic diet No. 2965 of Steenbock and Black with regard to rickets-producing quality, as

judged by the percentage of ash in the dry fat-free femur and the width of the uncalcified cartilage of the tibia. Diet No. 803, containing 0.28 percent of phosphorus, 52 percent of which is in the form of phytin, is deficient only in phosphorus, since the addition of phosphate (2 percent  $\text{KH}_2\text{PO}_4$ ) permitted normal growth as interpreted from the curve obtained by plotting the log of the weight against the reciprocal of time (see above abstract). The addition of vitamin D to this (or to other low-phosphorus rickets-producing diets) prevented anatomical signs of rickets, but did not lead to normal growth or to bone ash values equal to those of stock-diet animals of the same age or of the same weight; phosphate addition was required to bring the composition to normal. "It is pointed out that the visual signs of rickets do not necessarily correspond to bone composition, and the differences between the experimental rickets of rats and the spontaneous rickets in other species are discussed."

**Effect of gelatine feeding upon the strength and fatigability of rats' skeletal muscle.** G. C. KNOWLTON (*Amer. Jour. Physiol.*, 131 (1940), No. 2, pp. 426-427).—It is pointed out that the studies by Ray et al. and by Hellebrandt et al. (*E. S. R.*, 84, p. 843) employed subjective criteria as to the point of fatigue, and that such criteria, while valid for measurements of fatigue as a psychic reaction, did not necessarily reflect the functional capacity of the muscle. The present experiments to determine the effect of gelatin upon the functional ability of muscle in rats were designed, therefore, to measure fatigability by objective tests. The procedure used involved exposure of the gastrocnemius muscle in anesthetized rats, attachment of the severed tendon to a torsion rod, and rigid fixing of the femur, followed by stimulation of the muscle with maximal induction shocks. The response of the muscle was magnified with an optical lever and recorded on film. When the tension returned to the base line the muscle was removed and analyzed for creatine. The tension curves were measured for maximum strength, for the time required for the response to fall to 10 percent of the maximum, and for the area under the curve to 10 percent of maximum strength. Comparison of the response of rats receiving by stomach tube for a week prior to the test a daily gelatin supplement of 0.5 gm. in 3 cc. of water with the response of rats receiving a similar glucose supplement indicated that the feeding of the gelatin supplements to the adult male rat leads to no changes in the muscle itself which enhance functional performance.

**Hemoglobin and plasma protein: Simultaneous production during continued bleeding as influenced by diet protein and other factors.** F. S. ROBSCHT-ROBBINS, S. C. MADDEN, A. P. ROWE, A. P. TURNER, and G. H. WHIPPLE (*Jour. Expt. Med.*, 72 (1940), No. 5, pp. 479-497).—Clinical experimental histories and data on protein intake and output are given for healthy dogs observed for their capacity to produce new hemoglobin and plasma protein while fed abundant iron and a limited protein diet under a condition of sustained anemia due to simple bleeding. The dogs varied in their response, some producing much hemoglobin and enough plasma protein to maintain a low normal plasma protein level, while others producing the same amount of hemoglobin developed a hypoproteinemia which continued; the ratio of plasma protein to hemoglobin varied from about 60 to 80 percent in the former group and from about 40 to 60 percent in the latter. In some dogs the total new formed blood protein amounted to about 30-40 percent of the total diet protein, indicating a remarkable capacity to conserve and use diet protein. With the simultaneous depletion of hemoglobin and plasma protein levels, the dogs were observed in all cases to give preference to hemoglobin manufacture regardless of the type of protein fed (liver, salmon, soybean, beef, casein, and amino acid supplements in some cases).

**Effect of intramuscular injection of sodium citrate on the prothrombin time of the blood.** B. G. P. SHAFIROFF, H. DOUBILET, and C. TUI (*Soc. Expt. Biol. and Med. Proc.*, 46 (1941), No. 1, pp. 136-139).—Six normal dogs varying in weight from 9 to 17 kg. received intramuscular injections of sodium citrate, the amounts injected (in 50 cc. of hypertonic solution) varying from 1.50 to 8.50 gm. and averaging 0.125 and 0.50 gm. per kilogram. In blood samples drawn just prior to injection, the prothrombin times average 11.8 sec. Thirty min. after the injection the average fall in prothrombin time was 17 percent, and by the end of 90 min. there was a 24 percent reduction. In one dog the prothrombin time was reduced 50 percent at the end of 1 hr. Coagulation time determined by the method of Lee and White was lowered within 60 min. to 48 percent of its original value; this decrease was paralleled by the reductions in calcium coagulation time and capillary coagulation time. Hematocrit estimations showed no characteristic variations. The characteristic fall in coagulation and prothrombin times invariably observed in the animals injected with sodium citrate were not observed in two normal dogs used as controls or in three other control dogs, two of which received NaCl (0.50 and 0.64 gm. per kilogram) and one of which received KCl (0.50 gm. per kilogram) injections. Hematocrit determinations on the several controls showed no characteristic variations.

**Calcification and ossification: Calcification in normal growing bone.** F. C. McLEAN and W. BLOOM (*Anat. Rec.*, 78 (1940), No. 3, pp. 333-359, pls. 3).—This introductory paper of the series describes the improved histological method by which many of the findings were obtained, and presents considerations fundamental to the series of experiments. The histological method involves positive staining of bone salts by impregnation with silver, counterstaining of cellular elements with hematoxylin and eosin, and the preparation of thin serial sections of the undecalcified bone embedded in hard nitrocellulose.

Calcification in the cartilage matrix is described. Analysis of the process indicates that this matrix has calcifiability conferred upon it when the adjacent cartilage cells reach a certain stage of development. The relationship of calcification to intracartilaginous ossification is discussed. The studies on rats, puppies, and kittens indicate that bone matrix in these animals is calcifiable when laid down, so that under optimum conditions of supply and transport of bone materials the matrix is usually calcified simultaneously with its deposition or so soon thereafter that no intermediate stage of uncalcified osteoid tissue is demonstrable. The center of ossification in the patellar tendon, later forming the anterior tubercle of the tibia; the calcification of the bone formed by ossification of the patellar tendon at its junction with the shaft of the tibia; and the insertion of the crucial ligaments in the tibia and femur are described. "Resorption of normal bone involves bone salt and organic matrix simultaneously. No evidence for the phagocytosis of bone salts by osteoclasts has been found."

**The metabolic behaviour of phosphorus.—III, Balance sheets of phosphorus in full-grown rats fed with tri-stearine and sodium inositol hexaphosphate.** A. WESTERLUND (*Lantbr. Högsk. Ann. [Uppsala]*, 8 (1940), pp. 209-232, figs. 5; *Swed. abs.*, pp. 231-232).—In the present study, in continuation of the series (*E. S. R.*, 83, p. 704), sodium inositol hexaphosphate was substituted for sodium phosphate as the source of phosphorus used to supplement the low-phosphorus diet fed to adult male rats for a 10-day experimental period. Intake and excretion of calcium and phosphorus were measured in the last 6 days of this period. The urinary excretion of phosphorus depended chiefly upon intake and to a considerably less extent upon fecal elimination, while the latter in turn was determined by the corresponding fecal elimination of cal-

cium and the consumption of phosphorus. The relation between intake and fecal excretion of phosphorus was of borderline significance, however, while that between calcium excretion and phosphorus excretion was clearly significant, indicating that heavy ingestion of calcium impairs the absorption of inositol phosphorus and vice versa. The urinary excretion of calcium, which amounted to no more than 3 percent of the total excretion, bore no relation to any of the concomitant variables. The fecal excretion of calcium was determined to a moderate extent by the corresponding ingestion of phosphorus, an increase in phosphorus consumption being followed by a slight decrease in fecal elimination of calcium, and also by the fecal excretion of phosphorus. No relation could be demonstrated between calcium consumption and fecal excretion of calcium. The results of the present investigation are considered to provide no basis for the opinion that inositol phosphorus should be less available for intestinal absorption than that from  $(\text{NH}_4)_2\text{HPO}_4$  or  $\text{Na}_2\text{HPO}_4 \cdot 2\text{H}_2\text{O}$ , compounds previously studied.

**Rise in serum copper following oral administration of copper sulfate.** A. SACHS, V. E. LEVINE, A. SCHMITT, and R. HUGHES (*Soc. Exptl. Biol. and Med. Proc.*, 46 (1941), No. 1, pp. 192-193, fig. 1).—Dogs maintained at constant weight were fasted for 18 hr., following which the basal copper level in the serum was determined hourly for 7 hr. The fasting serum copper values remained fairly constant. At the end of another 18-hr. fast, another serum sample was collected and  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ , at the rate of 2, 8, or 16 mg. per kilogram and dissolved in 400 cc. of water, was administered by stomach tube. Serum samples collected  $\frac{1}{2}$  hr. later and then hourly for 5 hr. were analyzed for copper content. Curves showing serum copper in milligrams percent in relation to time indicate that the feeding of varying amounts of copper sulfate definitely raised the serum copper above the basal level, the larger doses producing a more sustained rise than the smaller doses. At 8 mg. per kilogram the dogs retained the  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  very well, but doses as large as 16 mg. per kilogram usually caused emesis.

**The response of blood donors to iron.** A. C. SANTY (*Amer. Jour. Med. Sci.*, 201 (1941), No. 6, pp. 790-796, figs. 3).—The hemoglobin response of 27 active professional blood donors was studied under therapy with iron (four 3-gr. tablets of exsiccated ferrous sulfate daily) and without medication. There was regularly a depression of hemoglobin immediately after donations. With the addition of iron following a 500-cc. donation, there was a return to the previous hemoglobin level in an average of 11 days, this regeneration occurring about eight times more rapidly than when iron was withheld. "A rough calculation of the amount of hemoglobin in the total circulation revealed the fact that the average active donor in this series could not maintain a positive balance without iron medication. It was found that the response to iron usually continued after its withdrawal, indicating that the most effective time to administer iron is before blood loss. It is concluded that the diet of regular donors should be supplemented with iron. Ferrous sulfate, because of its convenience and freedom from reactions, was regarded as a very satisfactory form of iron for blood donors."

**Studies in tooth development: The growth pattern of human teeth, I, II.** I. SCHOUR and M. MASSLER (*Jour. Amer. Dent. Assoc.*, 27 (1940), Nos. 11, pp. 1778-1793, figs. 9; 12, pp. 1918-1931, figs. 10).—The growth of enamel and dentin is traced and analyzed according to the stages of (1) initiation, (2) proliferation, (3) histodifferentiation, and (4) apposition. This latter stage is discussed in detail in terms of (a) the pattern of cellular activity and (b) the pattern resulting from the apposition of daily increments of enamel and dentin.

The approach, as indicated, is histophysiologic rather than histologic, and emphasis is given, therefore, to the general form or pattern of the developing tooth rather than its histologic structure, and to cellular dynamics rather than cytologic details. It is pointed out that the incremental lines of growth, giving rise to a tooth-ring picture similar to that of tree rings, are the result of a daily physiologic rhythm in cellular activity. Variations from the normal rhythm during growth are reflected in the tooth ring pattern. The time of the effect can be dated by the chronological position of the affected incremental layer, while the intensity of the condition is reflected in the degree to which this affected layer is deficient in growth or calcification. For the most part the cause of the effect is not recorded in the dental tissue, although the response to certain conditions, such as rickets or fluorosis, is often a characteristic syndrome or composite.

**Vitamin A supplies during a national emergency**, K. HICKMAN and G. C. MEES (*News Ed. (Amer. Chem. Soc.)*, 19 (1941), No. 11, pp. 623-625, figs. 2).—This survey, based on the rough generalization that half the population requires a vitamin A supplement of half the minimum daily requirement (requirement considered as 3,500 units per person) for half the year, estimates a minimum supplemental requirement of 22.4 trillion units per year for the whole United States. Data available on production of vitamin A oils (1939-41) and their use for medicinal, poultry feeding, and industrial purposes indicate that current supplies of vitamin A in the United States are more than sufficient for a minimum level of medication for the whole population. It is pointed out that future supplies can be increased by extracting the vitamin from those oils which now pass to industrial use, and, if necessary, that supplies can be spread further by wise distribution of dosage.

**The vitamin A values of 128 foods as determined by the rat-growth method**, L. E. BOOHER and R. L. MARSH (*U. S. Dept. Agr., Tech. Bul. 802 (1941)*, pp. 30, fig. 1).—According to an abstract by the authors, "the vitamin A content of a representative collection of 128 of the more common foods, determined by the rat-growth method, is reported in this bulletin. A brief review of the chemical and physical nature of the known vitamin A-active compounds and the available methods for the measurement of vitamin A activity are included. A detailed description of the method used in this study is presented."

**Teneur en vitamine A du sang des donneurs du centre de la transfusion de Paris** [Content of vitamin A in the blood of donors at the Paris transfusion center], A. CHEVALLIER and M. SUREAU (*Compt. Rend. Soc. Biol. [Paris]*, 134 (1940), No. 7, pp. 387-389).—A group of 30 apparently healthy universal blood donors gave vitamin A blood serum values, determined spectrophotometrically, ranging from 5 to 68  $\mu\text{g. per 100 gm.}$  With values between 40 and 50  $\mu\text{g. per 100 gm.}$  considered as normal, between 30 and 40 as sub-clinical, and below 30  $\mu\text{g. per 100 gm.}$  as indicating definite vitamin A deficiency, 40 percent of the subjects could be considered as normal, 37 as sub-clinical, and 23 percent as definitely deficient in vitamin A. The vitamin (dosage not stated) was then administered daily for 10 days, and after a further 10-day period blood values were again determined, with a resulting range of from 16 to 100  $\mu\text{g. per 100 gm.}$  In 22 cases the values were higher than before vitamin A treatment, in 6 cases the same, and in 7 lower (attributed to faulty assimilation).

The importance of liberal intakes of vitamin A by blood donors is emphasized.

**Effect of administration of thyroid extract and of  $\alpha$ -dinitrophenol upon dark adaptation**, A. J. PATEK, JR., and C. HAIG (*Soc. Expt. Biol. and Med. Proc.*, 46 (1941), No. 1, pp. 180-182).—In this preliminary report evidence is sum-

marized indicating that the oral administration of thyroid extract or  $\alpha$ -dinitrophenol increases the speed of dark adaptation and lowers the visual threshold in subjects with prolonged dark adaptation. In four of five experiments serum vitamin A levels were lowered by the therapy. In the fifth a rise in serum vitamin A and a striking reduction in serum carotenoids from an abnormally high to a normal level occurred. The fact that both forms of therapy produced the same result suggested that the visual changes were functions of general metabolism, but in two of the subjects the maximal visual effects occurred before changes in the basal metabolic rate were evident, and in the other there was no correlation between the basal metabolic rate and the speed or extent of dark adaptation. The improvement in dark adaptation was greater in the rods than in the cones, the response thus resembling that in vitamin A therapy. "The decrease in serum vitamin A level accompanying the improvement in dark adaptation suggests that the feeding of thyroid extract or of  $\alpha$ -dinitrophenol to these patients facilitated the utilization of vitamin A by the visual mechanism."

**Vitamin B<sub>1</sub> (thiamine hydrochloride)** (*Rahway, N. J.: Merck & Co., 1941, pp. [2]+31*).—A supplement, dated November 1941, to the previously noted bibliography (E. S. R., 86, p. 423).

**Vitamin B<sub>1</sub> in vertebrate muscle**, M. PYKE (*Biochem. Jour.*, 34 (1940), No. 10-11, pp. 1341-1347, fig. 1).—The vitamin B<sub>1</sub> contents of various muscles were determined in a number of domestic and experimental animals and specimens from the zoo. The thiochrome method, as modified by the author (E. S. R., 85, p. 701), was used. The muscles of the pig were several times richer in vitamin B<sub>1</sub> than those of any other animal. The normal variation of vitamin B<sub>1</sub> in pig muscle ranged from 170 to 510 International Units per 100 gm., as determined on random pigs obtained from bacon factories. Variations also occurred in the amount of vitamin B<sub>1</sub> in different muscles in any one animal. In the pig the psoas muscle was found to contain from 200 to 485 I. U. per 100 gm., while the longissimus dorsi contained from 160 to 340 I. U. per 100 gm. In the kid a range of from 4 to 63 and in the horse from 4 to 6 I. U. per 100 gm. was obtained in the various muscles analyzed. Heart muscle from various animals contained from 70 to 170 I. U. per 100 gm. The concentration of vitamin B<sub>1</sub> was higher in the ventricles than in the auricles. Red muscles of rabbits appeared to contain more vitamin B<sub>1</sub> than the white muscles, the range in values being from 12 to 63 and from 10 to 36 I. U. per 100 gm., respectively. In muscle allowed to stand after death there was apparently a breaking down of cocarboxylase, free vitamin B<sub>1</sub> appearing in such pig muscle, while vitamin B<sub>1</sub>-monophosphate apparently formed in horse heart.

**A preliminary survey of the vitamin B<sub>1</sub> content of American cereals**, A. S. SCHULTZ, L. ATKIN, and C. N. FREY (*Cereal Chem.*, 18 (1941), No. 1, pp. 106-113).—The vitamin B<sub>1</sub> content, determined by the method of the authors (E. S. R., 83, p. 417) and expressed as gamma per gram, varied from 4.2 to 7.3 in 31 samples of wheat, from 3.8 to 9.2 in 37 of barley, from 4.1 to 8.0 in 23 of corn, from 4.8 to 10.3 in 21 of oats, from 4.0 to 5.7 in 10 of rye, from 4.2 to 8.5 in 5 of buckwheat, and from 6.0 to 8.2 in 3 samples of millet. The results presented are considered only preliminary but sufficient to indicate that "there are significant differences in the thiamin content of various strains of the same cereal, and there are indications that regional differences may affect the thiamin content of a single strain. In view of the spread in values which is observed in most of the cereals it is not possible to evaluate a diet or food mixture containing cereals without analysis of the ingredients."

**The thiamin content of whole-wheat and clear flours**, C. HOFFMAN, T. R. SCHWEITZER, and G. DALBY (*Cereal Chem.*, 17 (1940), No. 6, pp. 733-736, fig. 1).—

Data taken from continuous routine assays, including many made on flours actually used in production, are reported for flours analyzed for ash and for thiamin content as determined by the fermentation method of Schultz et al. (E. S. R., 79, p. 11). Forty-six whole-wheat flours, including 24 special samples from known regions and 22 samples from commercial shipments, varied from 5.0 $\gamma$  to 8.7 $\gamma$ , and averaged 6.85 $\gamma$  of thiamin per gram on the 10 percent moisture basis. "There was no correlation with ash content and no special trend toward high or low vitamin contents in various parts of the wheat-producing areas except that the white or softer type of wheat tended to be somewhat lower than the average." The thiamin content of 18 clear flours varied from 2.0 $\gamma$  to 4.7 $\gamma$  per gram, and showed a definite relation to the ash content.

**Thiamin deficiency in relation to wheat flour**, A. W. ALCOCK (*Canad. Chem. and Process Indus.*, 25 (1941), No. 1, pp. 3-7).—This discussion of general problems involved in the fortification of white flour with synthetic thiamin voices certain objections to the requirement of the British Ministry of Food for the addition of 0.2 gm. of thiamin per 280 lb. of flour (0.82 International Unit per gram). One objection is that at Canadian prices this would be an expensive ingredient, and another is that the addition of thiamin alone does not make good the loss of minerals and other vitamins sustained in the milling process. Enrichment with high vitamin yeast and with wheat germ and the use of long extraction rather than short patent flours are discussed pro and con as alternate methods of increasing the thiamin content of wheat products.

**The loss of thiamin in bread on baking and toasting**, C. HOFFMAN, T. R. SCHWEITZER, and G. DALBY (*Cereal Chem.*, 17 (1940), No. 6, pp. 737-739).—The thiamin content of the caramelized part of the crust, the half inch of the slice immediately under the crust, and the interior of the slice (1 sq. in.), and the entire slice was determined in three types of bread by the fermentation procedure of Schultz et al. (E. S. R., 79, p. 11). These several portions, respectively, averaged 1.0 $\gamma$ , 1.2 $\gamma$ , 1.2 $\gamma$ , and 1.1 $\gamma$  per gram (dry basis) in regular white bread; 6.9 $\gamma$ , 8.7 $\gamma$ , 10.8 $\gamma$ , and 10.2 $\gamma$  per gram in high vitamin B<sub>1</sub> bread; and 5.3 $\gamma$ , 6.7 $\gamma$ , 7.5 $\gamma$ , and 6.8 $\gamma$  per gram in whole-wheat bread. Baking loss, calculated as the percentage difference between the thiamin content of the interior of the slice and the average of the entire slice, amounted to 8, 5, and 9 percent in the three types of bread, respectively. Regular white, two samples of high vitamin B<sub>1</sub> white, and whole-wheat breads having thiamin contents of 1.0 $\gamma$ , 4.9 $\gamma$ , 12.3 $\gamma$ , and 6.7 $\gamma$  per gram (dry basis), respectively, showed losses of 0, 4, 12, and 0 percent, respectively, with light toasting; 0, 10, 17, and 3 percent with medium toasting, and 0, 24, 21, and 12 percent with heavy toasting.

**The baker's "A B C" on bread enrichment** (*Southwest. Miller*, 19 (1941), No. 51, pp. 19-20).—This general outline of the A B C's of the "enriched" bread program for the baking industry, prepared by the American Bakers' Association, gives information concerning the required ingredients for enriched bread and the methods that may be pursued for its production, and comments briefly on costs, legal standards ultimately to be fixed, and advantages.

**Bakers' viewpoints on vitamins in bread**, J. A. TOREY (*Southwest. Miller*, 19 (1941), No. 48, pp. 19, 38).—Referring to "enriched" bread, the author points out the several propositions the baker must consider in deciding to produce this special vitamin bread. Effective methods of making the vitamin additions and the cost of these added components (probably only a fraction of a cent per pound loaf), labor involved, promotion needed, and the likelihood of a local demand for such bread are the chief items considered.

**Vitamin-rich baked products**, R. E. CARR (*Michigan Sta. Cir.* 178 (1941), pp. 15).—Recipes are given for breads, cakes, and cookies made with the addi-

tion of dry brewers' yeast (not the yeast ordinarily used in bread making) or wheat germ as ingredients to increase the amount of the vitamin B complex in the baked products. It is pointed out that the use of brewers' yeast modifies the texture of the baked product unless the batters and doughs are baked immediately after the yeast has been added, and that the flavor, which is objectionable to some individuals, should be masked through the use of molasses, honey, or spices. The use of wheat-germ flakes produces baked products of coarser texture than is otherwise obtained, but the danger of weakening the structure is lessened if the flakes are added at the very last of the mixing.

**The activation of cocarboxylase by thiamine**, M. A. LIFTON and C. A. EVERHEM. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 136 (1940), No. 3, pp. 637-651, figs. 3).—Decarboxylation of pyruvic acid by yeast carboxylase does not occur with yeast washed with alkaline phosphate buffer, but addition of cocarboxylase (thiamin pyrophosphate) and manganese or magnesium restores activity. The effect is considered specific for cocarboxylase, since neither thiamin nor thiamin monophosphate activates the carboxylase. Studies are described which show, however, that the cocarboxylase itself is strongly activated by thiamin in systems employing bakers' yeast, whereas only very minor activation occurs in systems employing brewers' yeast. "The mechanism of thiamin activation of cocarboxylase has been investigated. It is suggested that there is a heat-labile material present in bakers' yeast which can adsorb cocarboxylase without the production of an active enzyme. The addition of excess thiamin saturates this material and thus permits the adsorption of the cocarboxylase upon the active apoenzyme."

**The estimation of vitamin B<sub>1</sub> in urine**, M. JOWETT (*Biochem. Jour.*, 34 (1940), No. 10-11, pp. 1348-1355, fig. 1).—In the modified thiochrome method described, the blank fluorescence is said to be lowered considerably by the use of (1) a synthetic zeolite Decalso in place of activated earths and (2) of a considerable excess of the ferricyanide solution. Two types of blanks are distinguished—a reagent blank determined in the absence of urine and the urine blank representing the difference between the reagent blank and the total blank. In practice a value midway between the total blank and reagent blank is used in the calculations. Color readings are made with the Pulfrich photometer. The method is considered unsuitable for estimating low dietary excretions, but is suitable for measuring the response to test doses.

Data obtained with the modified method "support the view that maximum excretion occurs soon after the passage of most of the vitamin into the intestine, and that the variability of the lag between ingestion and maximum excretion is due to variability in the rate of emptying of the stomach."

**Determination of vitamin B<sub>1</sub> requirement of infants by means of urinary excretion of thiamin**, E. M. KNOTT (*Soc. Expt. Biol. and Med. Proc.*, 45 (1940), No. 3, pp. 765-766, fig. 1).—Evidence on the vitamin B<sub>1</sub> requirement of infants is summarized from a series of 5-day balance studies on 12 healthy male infants during the first 6 mo. of life in which the vitamin B<sub>1</sub> intake was controlled at values from 21 to 313 units [International] through the amount and type of milk fed or by the addition of thiamin to the formula.

Only small quantities of the vitamin were excreted in the stools and with intakes up to 80 units only a small fairly constant amount in the urine. Beyond this point urinary excretion increased more or less regularly with intake up to 140 units, when much larger amounts were excreted. From these findings it is suggested that 80 and 140 units may represent the minimum and maximum quantities of thiamin needed by infants of this age, with a range of from 100 to 150 units representing the optimum intake.

Determinations over a period of 9 weeks of the cocarboxylase content of the blood of two infants on increasing amounts of thiamin showed that with one of the subjects from 42 to 56 units were not sufficient to maintain the cocarboxylase level, while the other subject did maintain the level on an intake of from 49 to 58 units. These data point to 60 units as barely sufficient and substantiate the conclusion based on the urine excretion that 80 units represent the minimum requirement.

**Assessment of the level of nutrition: Urinary excretion of aneurin at varying levels of intake.** Y. L. WANG and J. YUDKIN (*Biochem. Jour.*, 34 (1940), No. 3, pp. 343-352, figs. 4).—The daily outputs of aneurin (thiamin) of three healthy male subjects over a wide range of intake were determined by the thiochrome method following the technic of Wang and Harris (*E. S. R.*, 83, p. 851); a special study (using four subjects) was made of the level of excretion with an intake corresponding to the reputed requirement (300 International Units or 900  $\mu$ g.); and finally the effects on thiamin excretion of exercise and of variations in the proportions of fat and carbohydrate in the diet were studied on three subjects.

On the basal diet furnishing from 100 to 150  $\mu$ g. of thiamin the excretion value fell rapidly, reaching fairly constant low levels in 5 or 6 days. With increased intakes the excretion rose only slightly until the intake reached 1,200  $\mu$ g., at which there was a sharp increase in excretion. The average daily excretion for 7 days on an intake of 900  $\mu$ g. ranged from 137 to 235  $\mu$ g. From curves of intakes plotted against excretion it was estimated that from 50 to 80  $\mu$ g. of thiamin would be excreted daily on a diet completely free from the vitamin. Additional carbohydrate in the diet in the form of 100 gm. of glucose for 1 day, and 200 gm. daily for a further 4 days and exercise amounting to an equivalent of approximately 500 calories daily for 2 days caused a slight decrease, and an increase in the fat content of the diet by 200 gm. added for 4 days a less definite decrease in the thiamin excretion.

**Verhalten des Aneurins und des Pyrophosphorsäuren aneurins (Cocarboxylase) im Blute bei der B<sub>1</sub>-Vitaminbelastung [Behavior of aneurin and aneurin pyrophosphate (cocarboxylase) in the blood in vitamin B<sub>1</sub> saturation tests],** S. MORÁNAR and M. HORÁNYI (*Klin. Wchnschr.*, 19 (1940), No. 45, pp. 1165-1167).—In an extension of earlier noted studies (*E. S. R.*, 84, p. 704) evidence was obtained that increases in the vitamin B<sub>1</sub> content of the blood and urine following test doses furnish a more satisfactory index of vitamin B<sub>1</sub> status than similar blood cocarboxylase values.

**Further experiments on nutritional achromotrichia in rats and mice,** P. GRÖGNY and C. E. POLING (*Soc. Expt. Biol. and Med. Proc.*, 45 (1940), No. 3, pp. 773-776).—From data obtained in a repetition of earlier experiments on nutritional achromotrichia in rats (*E. S. R.*, 83, p. 134) and an extension of the work to black mice, the authors conclude that "pantothenic acid is only one, although probably the most important, factor in the prevention of nutritional achromotrichia as it is seen in rats and mice used in experiments in the vitamin B<sub>1</sub> complex. Biotin is an additional factor that is connected with the maintenance of the normal pigment metabolism of the fur in rats and mice under special dietary conditions."

**p-Aminobenzoic acid, a vitamin,** S. ANSBACHER (*Science*, 93 (1941), No. 2407, pp. 164-165).—Data are summarized demonstrating the cure of nutritional achromotrichia in rats by the daily administration of 1 cc. of a 20-percent ethanol solution containing 3 mg. per liter of p-aminobenzoic acid. Likewise, chicks on the vitamin K-deficient ration previously described (*E. S. R.*, 85, p. 714), supplemented with calcium pantothenate and the vitamin K-active 2-methyl-1,4-

naphthoquinone, grew better and had longer survival periods when the ration was supplemented with *p*-aminobenzoic acid in spite of severe dermatitis symptoms similar to the ones described by Hegsted et al. (E. S. R., 84, p. 803). From these findings it is concluded that *p*-aminobenzoic acid is one of the factors of the vitamin B complex.

**Confirmatory evidence of the chromotrichial activity of *p*-aminobenzoic acid,** G. J. MARTIN and S. ANSBACHER (*Jour. Biol. Chem.*, 138 (1941), No. 1, p. 441).—It is noted briefly that *p*-aminobenzoic acid has proved effective in darkening the fur of mice in which graying had been produced on the McCollum stock diet with hydroquinone added in amounts of 100 mg. per kilogram. This is thought to afford further evidence that *p*-aminobenzoic acid is a chromotrichia factor and that hydroquinone achromotrichia is a vitamin deficiency.

**Inefficacy of pantothenic acid against the graying of fur,** R. R. WILLIAMS (*Science*, 92 (1940), No. 2398, pp. 561-562).—Evidence from three series of tests on rats is reported, indicating that, contrary to the findings of György and Poling (E. S. R., 85, p. 134), neither pantothenic acid concentrate nor pure pantothenic acid is capable of preventing or curing achromotrichia in rats on a diet furnishing all of the other known components of the B complex. The principal difference between the diets used by the author and by György and Poling is that in the former 2 percent of corn oil is used instead of 8 percent of butterfat, as in the latter. It is suggested that this difference might result in significantly different amounts of the factor described by Nielson, Oleson, and Elvehjem (E. S. R., 83, p. 382).

**Growth and graying of rats with total "filtrate factor" and with pantothenic acid,** G. A. EMERSON and H. M. EVANS. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 46 (1941), No. 4, pp. 655-658).—Hooded or solid-colored male rats were placed at weaning on a diet deficient in the vitamins of the B complex but supplemented with 15  $\mu$ g. of thiamin per rat daily except Sunday. When growth had ceased (at the end of 4 weeks) the diet was further supplemented with 20  $\mu$ g. of riboflavin and 15  $\mu$ g. of pyridoxin plus one of the substances to be tested, which included calcium pantothenate, the equivalent of 5 gm. of liver in the form of a filtrate from which thiamin, riboflavin, and pyridoxin had been removed by repeated adsorptions on fuller's earth, and the residue from the molasses preparation previously described as stimulating growth and preventing graying (E. S. R., 84, p. 561).

The various observations reported are thought to demonstrate that the pantothenic acid requirement for maintaining normal color of the fur is greater than for growth, or that some additional factor, or factors, is required. As noted above, biotin has been suggested by György and Poling and *p*-aminobenzoic acid by Ansbacher as antiachromotrichia factors. Preliminary tests showed that inositol, while improving the growth of the controls, did not alter the rate of growth or improve the condition of the fur to any greater extent than calcium pantothenate. The diet employed was sufficiently high in casein to rule out the possibility of choline deficiency, and the addition of choline did not further improve the filtrate factor deficiency condition.

**Nicotinic acid derivatives in human urine and their determination,** W. A. PERLZWEIG, E. D. LEVY, and H. P. SABETT (*Jour. Biol. Chem.*, 136 (1940), No. 3, pp. 729-745, fig. 1).—Difficulties encountered in the determination of nicotinic acid in the urine by the various methods hitherto reported are summarized, and methods are proposed in which hydrolysis with concentrated hydrochloric acid plus a very small amount of concentrated nitric acid is used for the preparation of the material for the determination of total nicotinic acid, including nicotinamide and nicotinuric acid but exclusive of trigonelline, and

subsequent alkaline hydrolysis for the determination of trigonelline. Lloyd's reagent at a relatively high H-ion concentration (pH 1 or less) is used to adsorb the nicotinic acid derivatives, with subsequent recovery of the active material by washing with dilute acid and eluting with dilute alkali. Reaction with *p*-aminomethylphenol sulfate, as employed by Bandier and Hald (E. S. R., 82, p. 586), was found to be the most satisfactory of various reactions proposed for the color development, the readings being made in an Evelyn photoelectric colorimeter with the 400 filter.

The advantages and limitations of the method described are discussed, and data are reported on its application.

Subjects on an adequate diet were found to excrete daily from 1 to 3 mg. of nicotinic acid derivatives exclusive of trigonelline, the latter amounting to from 20 to 29 mg. daily on diet without coffee and up to 200 mg. daily with coffee. Following the ingestion of pure nicotinic acid in doses of from 100 to 500 mg. daily, the increases in both fractions excreted accounted for only from 10 to 25 percent of the ingested nicotinic acid.

**Vitamin B<sub>6</sub> (pyridoxin) deficiency in human beings.**—Further studies, with special emphasis on the urinary excretion of pyridoxin, T. D. SPIES, R. K. LADISCH, and W. B. BEAN (*Jour. Amer. Med. Assoc.*, 115 (1940), No. 10, pp. 839, 840).—A method for detecting pyridoxin deficiency by the response in urinary excretion to a test dose is described, and data are reported on its application. Under the conditions specified the normal subjects examined excreted from 6.7 to 10.9 percent of the injected pyridoxin as compared with from 0.0 to 0.2 percent excreted by subjects maintained on a pyridoxin-free diet for 3 weeks, from 0.0 to 0.5 percent by ambulatory patients suspected of pyridoxin deficiency, and from 5.4 to 13.2 percent by cured patients.

**Vitamin C studies on paprika** [trans. title], T. JACHIMOWICZ (*Biochem. Ztschr.*, 307 (1941), No. 5-6, pp. 387-399, fig. 1).—A number of varieties of paprika, classified as vegetable and condiment varieties, were analyzed for vitamin C content by 2,6-dichlorophenolindophenol titration of a metaphosphoric acid extract of the fruit flesh. Seeds and placenta were discarded. The influence of cooking and of refrigerated and frozen storage was also investigated. The results (tabulated) are interpreted as indicating that cooking caused little actual destruction of vitamin C, but due to the solubility of the vitamin some was lost into the cooking water. In the cooking water there was some destruction, especially in the first 10-min. period before the soluble oxidases were destroyed. This loss due to oxidation was diminished by the use of vinegar in place of water. Storage at about 4° C. for as long as 1 mo. caused little or no loss of vitamin C, but freezing storage of unblanched fruits at -10° to -20° caused considerable loss (33-93 percent) in this period. Blanching previous to freezing did not reduce the loss. Values for the fresh fruits ranged from 112 to 214 mg. percent in the vegetable varieties and from 32 to 342 mg. percent in the condiment varieties. Paprika fruits packed in vinegar either with or without preliminary storage in a 12 percent salt solution lost most of their vitamin C.

**Concentration of ascorbic acid in the plasma during the treatment of infantile scurvy**, R. L. MINDLIN (*Jour. Ped.*, 17 (1940), No. 5, pp. 621-625, figs. 3).—Changes taking place in the plasma concentration of ascorbic acid in three infants during the healing of scurvy on vitamin C treatment are reported as evidence of the inadequacy of the ascorbic acid level in the plasma as an index of vitamin C nutrition. The three patients became symptom free within 48 hr. of the beginning of treatment, and X-ray evidences of healing were demonstrable in from 11 to 13 days in spite of wide differences in the ascorbic acid

concentration of the plasma. Immediately prior to the doses which resulted in a marked rise in the fasting level of ascorbic acid, the plasma values for the three subjects were 1, from 0.2 to 0.3, and 0.1 mg. per 100 cc.

"From the evidence reported herein and that available in the literature, the following statement may be made regarding the plasma ascorbic acid: A single, high fasting value indicates adequate ascorbic acid nutrition; a single, low fasting value indicates absence of ascorbic acid saturation, but not how far removed saturation may be; it has little value in the precise measurement of ascorbic acid undernutrition. Such measurement is better made by the determination of the ascorbic acid content of whole blood, the white cell-platelet fraction of blood, or the plasma concentration responses to parenterally administered test doses of ascorbic acid."

**Vitamin K in hemorrhagic disease of the newborn infant, C. E. SNELLING** (*Jour. Ped.*, 17 (1940), No. 5, pp. 615-620, fig. 1).—Daily administration by mouth of 1-mg. doses of 2-methyl-1,4-naphthoquinone to 60 mothers for from 2 to 16 days before delivery had no effect on their prothrombin times as judged by comparison with values obtained on a group of 100 mothers not receiving the therapy. Treatment of the mothers did, however, produce a shorter prothrombin time of the cord blood of infants, 64 percent of whom had prothrombin times within the interval of 30-60 sec., 34 percent in the interval of 60-90 sec., and only 2 percent with longer prothrombin times. Infants of untreated mothers showed a distribution of 31, 39, and 29 percent in these groups, respectively.

In 11 cases of hemorrhagic disease of the newborn the prothrombin times varied from 160 sec. to no clot formation at all; after the bleeding had been arrested by various methods this time was 95 sec. or less. In the treatment of other infants with hemorrhagic disease it was found that vitamin K by mouth might not be retained or absorbed. Administered intravenously, the synthetic vitamin (2-methyl-1,4-naphthoquinone) produced no ill effect, lowered the prothrombin time, and stopped the bleeding. Such treatment, with transfusion in addition, if hemoglobin is low, is recommended. Vitamin K therapy of the mother is recommended as a preventive measure for hemorrhagic disease.

The author had the technical assistance of W. Nelson.

**The nature of the anti-alopecia factor, D. W. WOOLLEY** (*Science*, 92 (1940), No. 2391, pp. 384-385).—This is a brief announcement that both phytin, the salt of inositol phosphoric acid, and inositol are curative of mouse alopecia. "The above facts indicate that the mouse antialopecia factor is inositol or its derivatives. They suggest that inositol exists in liver in alkali-labile combination with a large molecule which renders the former nondialyzable. While it has been reported that inositol stimulates the growth of certain strains of yeast, its place in the nutrition of higher animals has not previously been observed."

**Identification of the mouse anti-alopecia factor, D. W. WOOLLEY** (*Jour. Biol. Chem.*, 139 (1941), No. 1, pp. 29-34).—This is the detailed report of the above noted investigation.

## TEXTILES AND CLOTHING

**Textiles and clothing [at the Bureau of Home Economics] (U. S. Dept. Agr., Bur. Home Econ. Rpt., 1941, pp. 13-18).**—This annual report of the program and accomplishments of the Textiles and Clothing Division (E. S. R., 84, p. 855) deals with the work on cotton hose, work clothes for women, making and buying clothing and household furnishings, protection of fabrics against damage by micro-organisms, and miscellaneous studies on fibers and fabrics.

**Bacterial degradation of felts.—I, A bacteriological technique for studying the degradation of felts, J. W. APPLING, O. A. SMITH, and D. FROMMULLER**

(*Paper Trade Jour.*, 113 (1941), No. 7, pp. 30-34, figs. 4).—"A critical analysis and evaluation of the steps necessary for measuring the amount of bacterial degradation in terms of reduction in tensile strength have been made for the purpose of standardizing the technic used."

**Use of the tension presser for determining shrinkage** (*Rayon Textile Mo.*, 22 (1941), No. 11, pp. 75-76, fig. 1).—In the test, applied to fabrics other than cotton and linen, a 10-in. square with sides parallel to warp and filling directions, respectively, is outlined, with the help of a rigid marking device, on a test specimen 22 by 22 in., and the corners and midpoints of the square are marked with indelible ink. The sample is washed under specified conditions, squeezed to remove excess water, smoothed out on the bed of a flat-bed press, and pressed until dry by lowering the head of the machine. Fifteen min. after removal from the bed of the press the dimensional change in warp and filling directions is determined.

The stability test is then applied to the specimen, which is dampened with a spray and mounted on a mechanical tensioning device consisting of four clamp bars, two of which are movable and two fixed. Weights are applied to the movable clamp bars, first in the direction of greatest change, immediately followed by application in the direction of least change. If gains of over 2 percent are obtained after applying the recommended weight, the fabric is retested using a smaller weight. The fabric is held under tension while being dried by placing a metal plate on the fabric and drying through the plate without moving it by use of a hand iron. After release of the tension, the fabric is allowed to lay flat for 15 min., when dimensional changes in warp and filling directions are again determined.

A fabric to be considered satisfactory in laundering or wet cleaning from a stability standpoint must not show more than a 2-percent plus or minus dimensional change in warp or filling measurement by this tension pressing method when compared with the original measurements. Fabrics satisfactory for dimensional stability when ironed with firm, moderate, light, and smooth tension in hand pressing are classed in groups 1-4, respectively. A fabric is classified as unstable when the tension necessary to restore it to  $\pm 2$  percent of the original dimension is impractical to apply in hand pressing.

**Physical properties of cotton corduroy for boys' clothing**, G. WHITE (U. S. D. A.). (*Amer. Dyestuff Rptr.*, 30 (1941), No. 12, pp. 295-298, 315-316, figs. 3).—Twelve cotton corduroy fabrics, representing 3 different types of construction of ground weave (described and illustrated), were purchased directly from manufacturers. The fabrics, sampled so as to show up variations within any one fabric, were tested by methods noted for breaking strength, weight, durability as measured by resistance to abrasion, colorfastness to light and to washing, changes produced by laundering, and other physical properties.

The data recorded indicate that the fabrics differed widely in nearly all physical properties, except compressional resilience; that the amount of finishing material was high in most cases; that variations in breaking strength were fairly large for many fabrics; that laundering increased the count of many fabrics by a small amount, increased their thickness by from 13 to 24 percent, decreased their weight (with one exception) by from 3 to 13 percent due to loss of finishing materials and of fibers from tufts, and decreased their breaking strength by from 1 to 27 percent in most cases, although some gained in breaking strength. Abrasion of the laundered fabrics in filling-wise and also warp-wise direction caused three-fourths of them to change in strength from between -5 and +1 percent, indicating that the ground yarns received little damage in abrasion. Changes in both breaking strength and thickness indicated that most

of the fabric stood up fairly well under abrasion. All but two of the fabrics stood up well in tests of colorfastness to light, and colorfastness to laundering showed that most of the corduroy fabrics could be washed satisfactorily so long as no bleaching agent was used.

The data were subjected to statistical analysis to obtain additional information concerning the variation between fabrics with respect to various physical properties. On the basis of these results, specifications are proposed in order to define the minimum quality of medium-weight cotton corduroy for boys' wear. These proposed requirements are under consideration as tentative specifications by a subcommittee of the American Society for Testing Materials.

**Serviceability of selected types of cotton and rayon knit underwear,** R. E. ROGERS, M. B. HAYS, and J. J. BROWN (*U. S. Dept. Agr., Tech. Bul. 803* (1942), pp. 22, figs. 5).—Cotton and rayon yarns of known history, knit into fabrics of comparable construction, all of which is noted in detail, were made into vests for girls and union suits for boys and placed in institution service. The 26 girls and 25 boys wore alternately a cotton and a rayon garment. Unworn garments, withheld for test at the beginning and end of the study, and 3 garments of each type and each fiber removed at regular intervals of 8 periods of wear and laundering were subjected to analysis. The bursting strength and the dry breaking strength of the new cotton material was greater than that of the new rayon and the wet breaking strength much greater. Both the copper number and the fluidity measurements showed that the cellulose of the cotton was much less damaged than that of the rayon.

With wear and laundering the breaking strength, bursting strength, and moisture decreased, while the copper number, fluidity, and ash increased. Weight per square yard and thickness had increased at the eighth wash because of shrinkage. Although there was a slow decrease from this time on, the values at the end of wear were greater than the original values. Fluidity tests, the most sensitive measure used in the study, showed that both cotton and rayon suits were more deteriorated chemically at 24 periods than the corresponding vests at 40. The vests lasted approximately  $1\frac{1}{2}$  times as long as the suits. When cotton was compared with rayon in an analysis of variance, type of fiber was significant for bursting strength and highly significant for wet breaking strength, copper number, and fluidity. The cotton and rayon suits wore on an average 30.7 and 17.5 periods, respectively, and the vests 43.5 and 34.8 periods, indicating that cotton garments lasted in general about  $1\frac{1}{2}$  times as long as the rayon. Cotton was more suitable than rayon for the strenuous service to which union suits were subjected, although not particularly more serviceable for the vests. It was observed that more mending was required as the percentage of elongation decreased with increased service.

## HOME MANAGEMENT AND EQUIPMENT

[Economic studies at the Bureau of Home Economics] (*U. S. Dept. Agr., Bur. Home Econ. Rpt., 1941, pp. 2-7*).—This report of the Division of Family Economics (E. S. R., 84, p. 856) points out some practical applications of the findings on consumption patterns of farm, village, and small-city families at different income levels; methods of improving family diets; nutritive value of free school lunches; and 5-ct. milk in the diets of families on relief.

**Household equipment and housing** [at the Bureau of Home Economics] (*U. S. Dept. Agr., Bur. Home Econ. Rpt., 1941, pp. 13-21*).—This annual report of the Division of Housing and Household Equipment (E. S. R., 84, p. 857) gives briefly the findings concerning electric hand irons, refrigerators, gas and electric ranges, and cooking utensils, and the minimum requirements for working space

and storage areas in kitchens for families of different sizes in middle- and low-income groups.

**Laboratory studies of methods for cleansing of eating utensils and evaluating detergents,** F. W. GILCREAS and J. E. O'BRIEN (*Amer. Jour. Pub. Health*, 31 (1941), No. 2, pp. 143-150, figs. 3).—This address presents the results of an experimental study to determine the effectiveness of an efficient detergent in water at 100°-120° F. (followed by rinsing with clean water at 120° or over) in removing bacterial soil from drinking glasses, and considers in detail a practical functional test for determining the cleansing index of basic detergent materials and proprietary detergents in removing protein and also greasy soil. "Based on the data accumulated in these studies, an efficient detergent for cleansing of eating, drinking, and cooking utensils may be defined as a substance or compound soluble in water, which at a temperature of approximately 120° will provide complete removal of all types of characteristic soiling materials in a short period of time; will produce a free-rinsing surface; will reduce to a minimum the formation of a film of precipitated mineral salts and similar substances on the washed surface; and will function effectively in waters of varying hardness.

**Survey of State laws and judicial decisions on bedding and upholstery,** S. MERRIN, J. M. MAYER, and S. P. KADANOVSKY (*U. S. Dept. Agr., Agr. Adjust. Admin., Consum. Counsel Ser., Pub. 9* (1940), pp. VII+160).—"This survey consists of three principal parts: (1) A presentation of the provisions of State laws regulating the manufacture and sale of bedding and upholstery, (2) a summary of Federal and State court cases in this field, (3) a chart together with a summary thereof comparing State sanitation and labeling requirements for new bedding and upholstery." The survey covers laws and decisions up to January 1940.

**A comparison of qualities and prices of sheets available in Missouri stores,** N. G. BENNETT (*Missouri Sta. Bul. 436* (1941), pp. 16).—Ninety-six brands of sheets, 21 sold as percale and 75 as muslin, and 56 brands of sheeting were included in this study, which showed that there was no definite relation between price and quality as judged by such factors as weight per square yard, tensile strength, and thread count. In most cases an increased amount of sizing was related to a decrease in price. When the cost of laundering at a commercial laundry was computed by weight for the estimated period of wear and added to the initial cost, the medium-weight muslin sheet, although less durable than the one of heavy muslin, proved to be the more economical, with an estimated saving of \$6.19. Similarly, the percale sheet was estimated as being \$2 cheaper than the average weight muslin sheet. Sheets made from unbleached sheeting were less expensive than those made from bleached sheeting of the same brand, but there was no difference in durability. Ready-made sheets of bleached sheeting cost only 6 ct. more than home-made sheets of the same brand of sheeting. The tested sheets shrunk more in the warp, or length, than they did in the filling threads, and the sheets with high thread count showed less shrinkage than those with a low thread count.

## MISCELLANEOUS

**Fifty-first Annual Report [of Alabama Station], 1940,** M. J. FUNCHESS ET AL. (*Alabama Sta. Rpt. 1940*, pp. 45, fig. 1).<sup>4</sup>

**Fifty-fourth Annual Report, Colorado Agricultural Experiment Station, [1941],** I. E. NEWSOM (*Colorado Sta. Rpt. 1941*, pp. 62).<sup>4</sup>

<sup>4</sup> The experimental work reported is for the most part referred to elsewhere in this issue.

**Publications available from the [Kansas] Agricultural Experiment Station** (*Kansas Sta. Cir.* 205 (1941), pp. [4]).—The available bulletins and circulars, classified under agricultural economics, agricultural production, and home economics, are listed.

**Bimonthly Bulletin**, [November 1941] (*North Dakota Sta. Bimo. Bul.*, 4 (1941), No. 2, pp. 19, figs. 7).—In addition to several articles noted elsewhere in this issue, this number contains North Dakota Farm Prices, by W. L. Ettesvold (p. 18), and Soil Science for the Layman, by W. M. Johnson (p. 19).

**Agricultura Experimental**, [September–October 1941] (*Agr. Expt. [Puerto Rico Univ. Sta.]*, 1 (1941), No. 5, pp. [8], figs. 7).—In addition to articles noted elsewhere in this issue, the number contains Algodon para la defensa [Cotton in Defense], by J. P. Rodríguez (pp. [2–3]); and Ganancia de \$24.00 por cuerda tuvieron los cosecheros de algodón "Sea Island" en la costa noroeste en 1940 [Profits of \$24 per Cuerda from Sea Island Cotton on the Northeast Coast Area in 1940], by L. M. Géigel (pp. [4–5]).

**Recent investigations in tropical and subtropical agriculture**, A. F. HILL (*Chron. Bot.*, 6 (1941), No. 19–20, pp. 441–443).—A digest of papers presented at the International Congress of Tropical and Subtropical Agriculture, held at Tripoli in March 1939.

**The natural resources of the Lesser Antilles**, W. H. HODGE (Mass. State Col.). (*Chron. Bot.*, 6 (1941), No. 19–20, pp. 448–449).—A general discussion.

**La agricultura en la Republica Argentina**, L. R. PARODI (*Chron. Bot.*, 7 (1942), No. 1, pp. 19–23).—A general outline including cereals, oil plants, fruits, sugar plants, tobacco, textiles, horticultural and forage crops, etc. (15 references).

**The Falkland Islands**, C. SKOTTSBERG (*Chron. Bot.*, 7 (1942), No. 1, pp. 23–26).—On the natural resources, with special reference to minerals and plants.

## NOTES

---

**Arkansas University and Station.**—The resignations are noted from the department of rural economics and sociology of Drs. W. H. Metzler, associate professor and associate, and E. E. Sparlin, assistant professor and assistant. Recent appointments include Arthur H. Thompson as instructor in agricultural engineering, and Runyon Deere and Aubrey Enoch as scientific assistants in the Cotton Branch and Fruit and Truck Branch Stations, respectively.

**Colorado College and Station.**—Dr. Ralph M. Weihing and Robert S. Whitney, assistant agronomists, have been granted leave of absence for military service. Otto H. Coleman, assistant agronomist, has resigned to take a similar position with the Division of Sugar Plants, U. S. D. A. Bureau of Plant Industry at Meridian, Miss. Frank J. Kapel, assistant in range management, has been granted 6 months' leave of absence as research assistant with an aircraft corporation.

**Iowa College and Station.**—A new agricultural engineering laboratory is under construction. Dr. Frank D. Blohm has been appointed assistant professor of veterinary pathology.

**Kansas College.**—Leonard B. Harden, assistant professor of agricultural economics, has resigned.

**Massachusetts Station.**—Dr. Helen S. Mitchell, research professor of home economics, who has been on leave of absence since July 1, 1941, for the purpose of assisting in the organization of the program of the U. S. Office of Defense Health and Welfare Services, has resigned in order to continue her services with that office.

**Minnesota Station.**—Dr. F. R. Immer, acting vice director since July 1941, has been appointed vice director in addition to his previous duties as professor of agronomy and plant genetics. Otto W. Swenson, agronomist and instructor at the Grand Rapids Substation, will become farm superintendent at University Farm vice L. B. Bassett, who is to retire on July 1.

A committee headed by the vice director and including a biochemist, an agronomist, and a plant pathologist has been appointed to plan and carry out research to determine the possibilities of leafy spurge as a rubber-yielding plant. Greenhouse plantings have been made to provide enough spurge latex for chemical and physical tests.

**Montana College and Station.**—Dr. Royse P. Murphy, assistant professor of plant breeding and assistant in agronomy and plant genetics in the Minnesota University and Station, has been appointed associate professor of agronomy and associate agronomist vice Dr. A. M. Schlehuber, resigned. Gestur W. Johnson, assistant in home economics research in the Colorado Station, has been appointed assistant in chemistry vice Donald R. McCormick, resigned.

**New York State Station.**—In an effort to speed up the testing of new spray and dust materials for the control of fruit diseases, three types of precision sprayers have been designed. For the most rapid testing of fungicides, particularly sulfur, glass slides are sprayed with the materials under test and the spore suspensions of the desired fungus are applied to the slides to determine

the comparative effectiveness of different sprays in killing the fungus. More reliable tests on foliage grown in the greenhouse are made with a horizontal type of sprayer which makes it possible to spray one half of a leaf, leaving the other half as a check. To approximate orchard conditions more closely, a small model orchard sprayer has been set up in the laboratory. This does not give as accurate control as the precision sprayers, but very uniform and reproducible coverage is obtained by placing the potted trees on a turntable and passing them through the spray for a definite period of time.

Dr. Oscar H. Hammer, assistant in research (entomology) at the Hudson Valley Fruit Investigations Laboratory, has resigned to conduct investigations on the control of fruit insects for a chemical company in Michigan. He has been succeeded by J. L. Brann, Jr.

**Ohio Station.**—Dr. William D. Pounden has been appointed assistant in the dairy department, and Cecil Fryman in charge of the Hamilton County Experiment Farm, the latter vice W. E. Weaver, retired.

**Pennsylvania College and Station.**—The retirement is noted of M. S. McDowell, director of agricultural extension since 1915 and associated for 8 years previously with the chemical and extension work of the institution.

**Rhode Island Station.**—L. M. Murphy, assistant pomologist, has been granted military leave of absence.

**South Carolina Station.**—Dr. G. B. Killinger, soil scientist, has been appointed associate agronomist in the Florida Station.

**South Dakota Station.**—Recent appointments to the staff include Dr. Leslie E. Johnson, associate animal husbandman; William H. Burkitt, assistant animal husbandman; Dr. Leon C. Snyder, assistant horticulturist; L. T. Smythe and Virgil H. Wintrode, assistant economists; F. M. Skelton, assistant dairy husbandman; Helen M. Ward, assistant home economist; David Williams, assistant poultry husbandman; and Howard M. Sauer, assistant rural sociologist. Three members have been granted leaves of absence for Army service: Gerald E. Korzan, assistant in agricultural economics; James C. Watson, assistant in animal husbandry; and Dr. W. E. Poley, head of the department of poultry husbandry. W. H. Peterson and Norris J. Anderson, assistant agricultural economists, are on leave of absence for graduate study, and Barbara Bailey, research assistant in home economics, and Vernon W. Noordsy, assistant poultryman, have resigned to go into commercial work.

**Vermont University and Station.**—Joseph E. Carrigan, director of extension, will succeed Dean J. L. Hills (E. S. R., 86, p. 433) on July 1 as dean of the College of Agriculture and director of the station.

**Wyoming University and Station.**—J. A. Gorman, assistant professor of animal production and assistant animal husbandman, was inducted into the Army on January 20 as First Lieutenant in the Quartermaster Corps.

**American Country Life Association.**—General operations of this association have been suspended. Its files have been stored at Purdue University, and requests for back numbers of publications may be sent to O. F. Hall at that institution. Youth Section Activities are being handled by E. L. Kirkpatrick, 744 Jackson Place, Washington, D. C. The Committee on Rural Education may be reached through its secretary, Iman Schotzman, 5835 Kimbark Ave., Chicago, Ill.

## WAR-TIME BIBLIOGRAPHICAL AIDS IN AGRICULTURAL RESEARCH

As a groundwork for further study and a means for avoidance of duplication, agricultural research workers depend at all times on bibliographical aids, but under war conditions it is particularly important that such aids should be fully mobilized and freely available. Existing agencies, such as the *Record*, more or less automatically reflect the change of emphasis in current experimentation and to the extent of their resources endeavor to render a service of immediate applicability to the new problems at hand. Additional agencies also arise to meet special needs, and still other auxiliaries which may have been conceived and developed prior to the emergency find an unexpectedly hearty welcome because of the opportuneness of their appearance.

One of the guides to publications related directly to the war has been *Agriculture in Defense*. This is a mimeographed list compiled in the Library of the U. S. Department of Agriculture. Most of the approximately 100 articles covered in each weekly issue are listed only by title, but in some cases brief annotations and quotations are given. Among the subdivisions are war and postwar planning, Government policy and program, food notes, labor, prices, fats and oils, forestry and lumber, fruit and vegetables, livestock and meat, machinery and storage and refrigeration.

Increased attention to Latin America may be noted from a number of sources. Of direct bibliographical interest is the *Inter-American Bibliographical Review*. This is a quarterly publication of the Inter-American Bibliographical and Library Association and is issued by the Educational Research Bureau at 1320 M Street NW., Washington, D. C. Its material includes annotated lists of articles related to inter-American affairs published in English and recent Latin-American publications and periodicals. In this connection it may be of interest to note that the same agency has issued a reference index to 12,000 Spanish American authors. Of somewhat similar scope is the List of Latin American Serials, which is a survey of exchanges available in United States libraries and is prepared for the American Library Association committee on library cooperation with Latin America.

While not identified with the war effort, the establishment by *Biological Abstracts* of a section of animal production and veterinary

science is a timely development. The section, which now may be obtained separately, segregates abstracts of animal breeding; physiology, pathology, and anatomy of livestock; animal husbandry, dairy husbandry, poultry, ranch, fur, and pet stock; veterinary science; veterinary parasitology and insect pests of animals; and dairy bacteriology.

Special mention may also be appropriately made in this connection of the appearance of the second edition of *Standardized Plant Names*. It is announced that this revision of the 1923 edition, prepared for the American Joint Committee on Horticultural Nomenclature, has been rendered imperative by a substitution for the American Code of the International Rules of Botanical Nomenclature. Other factors entering in have been the need to take account of the approximately 3,000 new plants, including importations, hybrids, strains, etc., which are being added annually under normal conditions to American horticulture and agriculture. There has also been a broadening of the field by the admission of terminology related to fields other than horticulture, notably agronomy, forestry, gums and latex, pharmacy, spice and condiments, range and wildlife management, and soil conservation.

In the making of this revision a large amount of cooperation from institutions, organizations, and individuals has been availed of. Among these has been the U. S. Department of Agriculture, which in 1939 set up a standing committee on plant names, headed by Dr. M. A. McCall of the Bureau of Plant Industry, "to consider and to recommend for use by the Department such plant nomenclature, both scientific and common names, as may be desirable."

Simplification of nomenclature may seem somewhat remote from the war, but, as already indicated, time-saving aids were never more essential. It is fortunate that those discussed and others of similar scope have become available.

## RECENT WORK IN AGRICULTURAL SCIENCE

---

### AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations by the Bureau of Agricultural Chemistry and Engineering] (*U. S. Dept. Agr., Bur. Agr. Chem. and Engin. Rpt., 1941, pp. 2-69*).—This report covers work on vegetable, fruit, cereal, and eggs and egg products; sugarcane and cane sugar; sugar beets and beet sugar; farm-made sirups and sorgo sugar; honey; starches; hemicelluloses; use of sweetpotatoes as feed; oil, fat, and wax investigations; proteins of agricultural food products; chemistry of enzymes and of miscellaneous plant constituents; microbiology of food products; pharmacology of possible food contaminants; effects of industrial contaminants on the composition of plants; and the chemistry of weed eradication.

Also included is the work on industrial utilization of farm products and by-products and on naval stores investigations, and special research (under Bankhead-Jones Act of June 29, 1935) on allergens of agricultural products, animal and plant viruses, preserving biological specimens related to agriculture, and on soybeans and soybean products, together with the work of the four regional research laboratories with corn, wheat, agricultural residues, cotton, sweetpotatoes, apples, vegetable wastes, potatoes, quick freezing of poultry, tobacco, milk products, and tanning materials.

[Chemical work of the U. S. Department of Agriculture] (*U. S. Dept. Agr., Sec. Agr. Rpt., 1941, pp. 227-230*).—Work of the regional research laboratories and various Department agencies is noted on dehydration and other ways of preserving foods, and research on fibers, hides, and skins.

[Chemical investigations by the Georgia Station] (*Georgia Sta. Rpt. 1941, pp. 108-112, 119-125, figs. 3*).—This report notes peach storage studies, analyses of pimientos, and food processing, including freezing lima beans, pilot refrigeration plant operations, peach peeling, and peanut processing.

An improved automatic continuous percolator, M. S. SCHECHTER and H. L. HALLER. (*U. S. D. A.*). (*Indus. and Engin. Chem., Analyt. Ed., 13 (1941), No. 7, pp. 481-482, fig. 1*).—Some improvements in an apparatus previously described (*E. S. R., 80, p. 295*) were found to be needed. A drawing of the revised set-up accompanies the note.

Magnetic stirrer for use in the cup type of moisture-transfusion apparatus, H. K. BURR and A. J. STAMM. (*U. S. D. A.*). (*Indus. and Engin. Chem., Analyt. Ed., 13 (1941), No. 9, p. 655*).—Three horizontally mounted pulleys serve as the supports for three moisture-transfusion cups (glass crystallizing dishes) slightly smaller in diameter than the pulleys. The cups may be clipped to the pulleys so as to be readily removable. Rings made by bending 18-gage sheet-iron strips 1 cm. wide into circular cylinders 3 cm. in diameter were completely covered with tinfoil on the circular surfaces, as well as on the ends, to make sealed drums. Small tinfoil vanes were sealed horizontally on the top faces of the drums. These drums weighed only 5 gm. each. They were floated on the liquid in the crystallizing dishes, after which the membranes were sealed to the top. Three electro-magnet coils, taken from old electric doorbells, were so mounted that each magnet surface just cleared the side of one of the crystallizing dishes. These electro-magnets were operated from the secondary of an ordinary doorbell transformer

(18 v.). When the pulleys were operated at about 60 r. p. m., the drums were held in a position near the electromagnets as the pulleys and crystallizing dishes rotated about their own axes. The vanes on the drums caused an efficient stirring of the air. The rotation of the crystallizing dishes with respect to the stirring drums also adequately provided a continual formation of a new liquid surface.

**A powder compactor for air-permeation experiments**, E. L. GOODEN. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 7, pp. 483-484, figs. 2).—Essentially the device consists of a sample tube fitted with a porous support for the sample and with a feed funnel having a stem of a diameter equal to that of the tube, a plunger fitting the tube but partly cut away at one side, and a plunger stem formed into shallow zigzag bends to the height to be occupied by the powder and continued as a straight handle. The powder placed in the tube above the plunger feeds gradually through the space between the cut side of the plunger and the tube wall during vertical oscillation of the plunger, while turning of the plunger about its vertical axis assists in making the feeding and tamping even and uniform.

**Observations with a photoelectric hemoglobinometer**, P. L. McLAIN and G. J. PASTORIUS (*Jour. Lab. and Clin. Med.*, 26 (1941), No. 6, pp. 1054-1057, figs. 2).—The instrument, an experimental model representing a simple form of photoelectric colorimeter consisting essentially of a single photoelectric cell, a filter, a holder for solution containers, and a light source, is described briefly as to construction and operation. A comparison of photometer readings with hemoglobin measurements by the gasometric method of Van Slyke and Neill and the blood iron method of Wong indicated that the photometric method was suitable for hemoglobin determinations. "Single readings were reliable within 0.3 to 0.7 gm. of hemoglobin per 100 cc., depending on the total hemoglobin content of the sample. Multiple readings, occupying an insignificant amount of extra time, narrowed the limits of error."

**A shaping lathe for graphite electrodes used in spectrochemical analysis**, K. R. MAJORS and T. H. HOPPER. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 647-648, figs. 2).—The essential features of the device reported upon consists of a head stock carrying a hollow housing, a shaping or trimming tool, and the concentric inner bit which forms the crater; and a guide trough and sliding carriage to support the electrode during the forming operation. The guide trough has the necessary height and alignment adjustments.

**Electrokinetics.**—XXIV, The electroviscous effect, I. XXV, The electroviscous effect, II. (Minn. Expt. Sta. et al.). (*Jour. Phys. Chem.*, 45 (1941), Nos. 5, pp. 866-876, fig. 1; 6, pp. 943-953, figs. 4; abs. in *Minnesota Sta. Rpt.* 1941, pp. 28-29, 30-31).—The two papers of this series (E. S. R., 85, p. 580) here noted deal with the electroviscous effect as exhibited, respectively, by solutions of sodium gum arabic and of calcium and sodium caseinates.

I. *In systems of sodium gum arabic*, D. R. Briggs.—The Smoluchowski equation for the electroviscous effect has been put into a form which makes possible its testing against experimental data obtained from measurements of the electrokinetic potentials ( $\xi$ ), specific conductivities ( $\lambda$ ), and relative viscosities ( $\eta_s/\eta_0$ ) on colloid-containing solutions. When the equation is written

$$\frac{1}{\eta_{sp}} = -\frac{3e^2}{8\pi^2r^2} \cdot \frac{\xi^2}{\lambda(\eta_s - \eta_0)} + \frac{1}{K\phi}$$

and the values of  $1/\eta_{sp}$  and  $\xi^2/\lambda(\eta_s - \eta_0)$  are chosen as coordinates in plotting the data, the values of  $K\phi$  and  $r$  can be obtained from the intercepts and slopes,

respectively, of the straight line obtained, provided the Smoluchowski equation is valid. Plotted in this manner, the data from sodium gum arabic, without and with the addition of small amounts of sodium chloride, fall on a straight line, and the values of  $K\phi$  obtained are proportional to the colloid concentration. This supports the validity of the equation. The slopes of the lines, however, at varying colloid concentrations, change in such a manner that the calculated value of  $r$  appears to decrease directly as the concentration of colloid increases. To this extent the equation is apparently not verified.

**II. In systems of calcium and sodium caseinates,** C. L. HANKINSON and D. R. BRIGGS.—The authors here present measurements of electrokinetic potentials ( $\zeta$ ), specific conductivities ( $\lambda$ ), and relative viscosities ( $\eta_s/\eta_0$ ) on systems of both calcium caseinate and sodium caseinate, without and with the addition of small amount of the chloride of the cation common to the colloid. These data, when calculated and plotted as variables in the linear form of the electroviscous equation, fall on a straight line. The values of  $K\phi$  calculated from the intercept are proportional to colloid concentration. This is in agreement with the results already obtained on sodium gum arabic systems. Other data concerning the protein systems and further comparisons between the protein and the gum systems are also noted.

**A Pyrex all-glass microelectrophoresis cell,** D. R. BRIGGS, (Minn. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 12 (1940), No. 11, pp. 703-705, figs. 2).—The manufacture and use of a Pyrex all-glass microelectrophoresis cell and the electrical circuits are described. This equipment was designed for measurements of the electrophoretic velocity and solid particles suspended in highly nonconductive organic liquids, but the apparatus may be used as readily for aqueous systems. Certain advantages of construction and arrangement of the cell make it relatively easy to use.

**Reversible aggregations of colloidal particles.—I, Centrifugal experiments on thixotropic iron oxide sols,** W. HELLER. (Univ. Minn.). (*Jour. Phys. Chem.*, 45 (1941), No. 8, pp. 1203-1227, figs. 11).—The author showed that when a thixotropic sol is centrifuged, it separates into an upper dilute sol phase and a lower concentrated phase, which is thixotropic. The experiments show that reversible aggregates (which can be destroyed by gentle shaking) develop in thixotropic sols. Their subsequent association to a gel structure leads to the transformation of the sols into gels. Centrifugation brings about settling of these reversible aggregates and their premature association. Besides the reversible aggregates, called "geloids" because they consist of minute elementary gels, irreversible ones are present in thixotropic systems in minor quantity. These settle swiftly in a centrifugal field, whereas the settling of the reversible aggregates is slow. In freshly shaken systems, settling of the irreversible aggregates starts immediately after centrifugation begins, whereas geloids start settling considerably later when they have again grown to a size such that settling becomes possible. The kinetics of the phase separation and the influence of various physical and chemical agencies upon this separation are discussed.

**The reaction of ethyl glycinate hydrochloride with primary, secondary, and tertiary Grignard reagents,** F. L. GREENWOOD and R. A. GORTNER. (Minn. Expt. Sta.). (*Jour. Organic Chem.*, 6 (1941), No. 3, pp. 401-409).—Ethyl glycinate hydrochloride reacted with *n*-propylmagnesium chloride to give approximately a 75-percent yield of 2-amino-1,1-di-*n*-propylethanol-1. The ester hydrochloride was also treated with isopropylmagnesium chloride and aminomethyl isopropyl ketone and 2-amino-1,1-diisopropylethanol-1 were isolated from the reaction mixture. The ester hydrochloride failed to react with *t*-butylmagnesium chloride. Converting the amino group to the amino hydrochloride failed

to protect the amino group from the Grignard reagent. All of the Grignard reagents reacted with the ester hydrochloride to yield the hydrocarbon corresponding to the Grignard reagent, and all three hydrogen atoms can be replaced if the reaction is allowed to proceed for a sufficient time.

**The origin of the humin formed by the acid hydrolysis of proteins.—IX, Hydrolysis in the presence of djenkolic and of thiazolidine-4-carboxylic acids, H. A. LILLEVIK and W. M. SANDSTROM.** (Minn. Expt. Sta.). (*Jour. Amer. Chem. Soc.*, 63 (1941), No. 4, pp. 1028-1030. fig. 1; abs. in *Minnesota Sta. Rpt.* 1941, p. 29).—In continuation of much earlier work (E. S. R., 52, p. 108), the authors showed that djenkolic and thiazolidine-4-carboxylic acids are cleaved to formaldehyde and cysteine (or cystine) after hydrolysis for 24 hr. with 20 percent hydrochloric acid, as shown by polarographic analysis, the Sullivan colorimetric analysis (E. S. R., 70, p. 444), and condensation of the derived formaldehyde with tryptophan. It has been found that a lesser amount of formaldehyde, as obtainable from these precursor compounds, is needed to bring about the maximum insoluble humin than when formaldehyde is added as trioxymethylene.

**Sulfur in proteins.—VI, Qualitative studies in the alkaline decomposition of cystine, H. V. LINDSTROM and W. M. SANDSTROM.** (Minn. Expt. Sta.). (*Jour. Biol. Chem.*, 138 (1941), No. 2, pp. 445-450).—Resuming a series earlier noted (E. S. R., 69, p. 483), the authors identified uvitic, uvitonic, and thiolactic acids for the first time as alkaline decomposition products of cystine and showed that these acids arise from the action of the alkali on the primary decomposition products, pyruvic acid, ammonia, and hydrogen sulfide.

Alanine was demonstrated as a product from a barium hydroxide decomposition. Since alanine was found to stabilize cystine somewhat in sodium and potassium hydroxide solutions but not in barium hydroxide solutions, a theory was put forth that alanine stabilizes cystine in alkaline solutions, the alanine arising from the decomposition of cystine and inhibiting the action of the cystine-labilizing factor, pyruvic acid. The result is that alanine is resynthesized and pyruvic acid (as well as any acetaldehyde derived from it) is removed by being condensed rapidly in sodium or potassium hydroxide but only slowly in barium hydroxide.

**Studies on soybean carbohydrates, M. M. MACMASTERS, S. WOODRUFF, and H. KLAAS.** (Ill. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 7, pp. 471-474).—This paper presents analytical data on sugars, galactans, and pentosans found in several edible varieties of soybeans from a very immature green vegetable stage to that of the mature seed. Total carbohydrates and total and reducing sugars tended to decrease as the beans became more mature, while galactans and pentosans tended to increase. Qualitative separation of hemicellulose fractions was attempted by methods heretofore employed with woody and herbaceous materials. The relatively large amount of protein present in soybeans interfered greatly in this procedure, but evidence was obtained that the hemicelluloses of soybeans are a mixture of galactoarabans containing galacturonic acid.

**A study of the moisture in soybeans, A. C. BECKEL and F. R. FARLE.** (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 1, pp. 40-43, figs. 9).—The authors report in some detail the behavior of several varieties of soybeans as to various oil and protein contents in four oven-drying methods, namely: Air oven at 105° and 130° C. and vacuum oven at 80° and 105°. The changes in weight were followed continuously by means of an apparatus developed for that purpose.

The dissimilation of glucose by *Chaetomium funicola* Oke.—I, Glucose carbon partition, G. SEMENIUK. (Iowa Expt. Sta.) (*Iowa State Col. Jour. Sci.*, 15 (1941), No. 3, pp. 261-268).—*C. funicola* slowly converted the glucose in Czapek-Dox solution mainly to carbon dioxide and mycelium over the entire tested period of 33 days' development. Products of the nonvolatile, nonacidic, and nonreducing class accumulated in the medium throughout this period. The maximum formation of these products occurred between the eighteenth and the twenty-sixth day of fungus development, when approximately 35 percent of the glucose carbon dissimilated in that period was converted into these products. Volatile and nonvolatile acids and volatile neutral compounds accumulated in only very small amounts. The medium gradually became alkaline with progressive development of the fungus. Ether extraction of the concentrated residual medium yielded a mixture of brownish, liquid fatty material and crystalline organic compounds possessing different melting points. Vigorous agitation of the culture medium by means of forced air did not hasten glucose dissimilation even though *C. funicola* grew throughout the medium.

The reducing properties of l-sorbose, F. K. BROOME and W. M. SANDSTROM. (Minn. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 4, pp. 234-235).—The reducing power of l-sorbose was determined by a ferricyanide method on a preparation carefully purified until its properties agreed with the best recorded data. The direct titration of the ferrocyanide with standard ceric sulfate is satisfactory in the concentration range of from 0.01 to 0.7 percent. Fructose, the only other common ketohexose, was found to have approximately 10 percent greater reducing power. These values are sufficiently similar to bear out the hypothesis that the configurations about the third and fourth carbon atoms are important in determining the reducing properties, these two ketohexoses having similar configurations on these carbon atoms and reducing properties of the same order of magnitude.

The chemistry and toxicity of selenium compounds, with special reference to the selenium problem, E. P. PAINTER. (N. Dak. Expt. Sta. and Univ. Minn.). (*Chem. Rev.*, 23 (1941), No. 2, pp. 179-213).—A critical survey of the literature through 1940 on organic selenium compounds and their toxicity, with especial reference to the nature of the form in which selenium occurs in seleniferous plants and grains. The subject matter is discussed under the four headings the selenium problem in agriculture, methods of analysis, organic compounds of selenium, and the properties of selenium in plants and their relation to known compounds of selenium and sulfur. One hundred and eighty-six references are appended.

Organic selenium compounds: Their decomposition in alkaline solutions and other properties related to the behavior of selenium compounds in cereals, E. P. PAINTER, K. W. FRANK, and R. A. GORTNER. (S. Dak. and Minn. Expt. Stas.). (*Jour. Organic Chem.*, 5 (1940), No. 6, pp. 579-589).—Organic diselenides, selenium ethers, and seleninic acids of acetic,  $\beta$ -propionic, *n*-propyl, and benzyl radicals were synthesized and their decomposition studied by hydrolyzing in alkaline solutions. Diselenides, like disulfides, decompose in alkaline solutions. Inorganic selenide and selenite formed. Selenium ethers, like sulfur ethers, were stable, but the selenide of propionic acid decomposed in alkaline plumbite to give nearly all the selenium as lead selenide. The selenium from seleninic acids of organic acids appeared to be quantitatively cleaved, while the seleninic acids of hydrocarbons were partially cleaved. Selenites and lead selenide were formed. It is probable that the mechanism of the decomposition of these compounds is the same as that of the corresponding sulfur compounds. The

relationship of the selenium compounds in plants, and synthesized compounds, in regard to their stability in different solutions and upon storage, is discussed.

**Determination of unsaturation in the terpene series,** L. M. JOSHEL, S. A. HALL, and S. PALKIN. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 7, pp. 447-449, figs. 4).—The usual halogen absorption methods, as well as those using standard potassium permanganate or standard perbenzoic acid, were found unsatisfactory for the determination of unsaturation in terpenes. Quantitative hydrogenation using either a platinum or a palladium catalyst furnished satisfactory results with a variety of terpenes, but not with the resin acids. High-pressure reduction was also shown to be a suitable quantitative method for terpenes.

**Photoelectric colorimetric technique for the dithizone system,** F. L. KOZELKA and E. F. KLUCHESKY. (Univ. Wis.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 7, pp. 484-487, figs. 3).—A technic adapted to photoelectric colorimeters for the determination of one component in a two-component system is described. The technic is especially adaptable to the dithizone system because it eliminates the necessity of removing the excess dithizone and the use of standard dithizone solutions. It simplifies considerably the procedure for routine analysis. Recoveries of  $\pm 1$   $\mu$ g. of lead are obtainable.

**A pendulum method for measuring settling velocities,** J. H. McMILLEN, L. F. STUTZMAN, and J. E. HEDRICK. (Kans. State Col.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 7, pp. 475-478, figs. 5).—The suspension was placed in a long tube and mounted so that the tube swung like a pendulum from a support just above the center of gravity of the suspension. As the suspended particles settled, the center of gravity of the system was lowered, causing the period of oscillation to shorten. The tube was also equipped with a second support just above the first one, and the periods of oscillation were measured for both supports. The data on these periods for various times of settling were then used to calculate the rate at which the center of gravity of the entire mixture was lowered, which gave a measure of the suspension's stability.

It was possible, by making certain simplifying assumptions regarding the nature of the settling process, to calculate also the rate at which the particles themselves were settling. The experimental results for the samples investigated agree reasonably well with the derived equations.

**Platinized silica gel as a catalyst in gas analysis,** K. A. KOBE and R. A. MACDONALD (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 7, pp. 457-459, fig. 1).—A platinized silica gel catalyst containing 0.125 percent of platinum was found to reduce the oxidation temperature of methane and carbon monoxide by approximately 100° C. below that obtained with a 0.075-percent catalyst. Temperatures for the complete oxidation of carbon monoxide, methane, ethylene, and acetylene and for the start of oxidation for ethane and propane are stated. Nitrous oxide may be reduced over the catalyst by a limited excess of hydrogen at 515°.

The catalyst tube can replace the copper oxide tube and explosion (or slow combustion) pipette in any commercial gas analysis apparatus. Large samples may be used without danger of explosion.

**Removal of nitrogen oxides in semimicrodetermination of carbon and hydrogen,** P. J. ELVING and W. R. McELBOY. (Purdue Univ.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 660-663, figs. 2).—The method used for the determination of carbon and hydrogen in nitrogen-containing compounds was improved by substituting for the lead dioxide in the combustion tube a sulfuric acid solution of potassium permanganate, or of some other oxidizing agent, placed between the absorption tubes used for water and for carbon

dioxide. Potassium permanganate and sulfuric acid are considerably cheaper and more convenient to use than other proposed nitrogen oxide absorbents which are similarly placed in the absorption train, and they are apparently equally efficient. If a method can be found for converting all the nitrogen in the sample to nitrogen oxides, the proposed method will suffice for the simultaneous determination of carbon, hydrogen, and nitrogen. An added advantage of the proposed method is that it permits the use of a simplified combustion tube filling whether or not compounds containing nitrogen are being analyzed. Various metals and metallic oxides were tested for their ability to decompose or absorb nitrogen oxides. Although some of the metallic oxides satisfactorily remove oxides of nitrogen, their use is excluded since unsatisfactory carbon and hydrogen values are obtained when they are present.

**Perchloric acid oxidation of organic phosphorus in lake waters**, R. J. ROBINSON (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 7, pp. 465-466).—Perchloric acid may be used in place of digestion with sulfuric and nitric acids followed by hydrochloric acid to destroy the excess nitric acid. Excess perchloric acid causes no fading of the blue molybdenum compound, and the excess of perchloric acid, therefore, does not need to be removed.

**A study of the ferric thiocyanate reaction**, C. A. PETERS and C. L. FRENCH. (Mass. State Col.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 604-607, figs. 2).—In general, the most favorable acidity is 0.01 N, larger and smaller amounts of acid giving less color. Increasing the thiocyanate overcomes the effect of higher concentrations of hydrochloric acid to lessen color intensity; also, at higher concentrations of thiocyanate less acid is needed to develop the same color intensity. Increasing the thiocyanate progressively increases the colored substance with no indication of reaching a maximum. A variation in quantity of iron, over a limited range, does not change the quantity of acid necessary for maximum color intensity. The minimum concentration of several anions which reduce the color intensity of ferric thiocyanate, within the limits of the experiments here cited, are stated in the decreasing order pyrophosphate, primary phosphate, tertiary phosphate, secondary phosphate, sulfate, chloride, and nitrate. The extraction of the red color by ether depends upon the CNS:Fe ratio, and a high ratio is necessary for iron extraction.

**Determination of sulfate in the presence of chromate**, W. B. MELDRUM, W. E. CADBURY, JR., and W. W. LUCASSE (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 7, pp. 456-457).—The authors reduce coprecipitation of chromate with the sulfate as much as possible by increasing the hydrochloric acid concentration. They then fuse the weighed precipitate of sulfate and chromate with sodium carbonate, dissolve the melt, and determine the chromate iodometrically.

**Use of bromate in volumetric analysis: Determination of arsenic and antimony using internal indicators at ordinary temperatures**, G. F. SMITH and R. L. MAY. (Univ. Ill.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 7, pp. 460-461).—The titration of trivalent arsenic and antimony in strong hydrochloric acid with potassium bromate, methyl orange, or indigo sulfonate as indicators, which requires a temperature of from 80° to 90° C., may be simplified by substituting as indicators the dyes Brilliant Ponceaux 5R, B. C. I. No. 185 (0.2 percent aqueous solution), bordeaux, B. C. I. No. 88, or naphthol blue-black, B. C. I. No. 246. These indicators permit carrying out the titration at room temperature and a wide range of HCl concentrations.

**Detection of certain metals in minerals and ores: An ammonium hypophosphite fusion method**, H. B. VAN VALKENBURGH and T. C. CRAWFORD (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 7, pp. 459-460).—When fused with ammonium hypophosphite many minerals and ores are decomposed, the result-

ing melt often being highly colored. The color of the melt directly, or after being treated with water or hydrogen peroxide, is the basis of tests for chromium, cobalt, columbium, manganese, molybdenum, tellurium, titanium, uranium, vanadium, and tungsten. Sodium and potassium hypophosphites are not suitable for this fusion because upon decomposition they form salts with relatively high melting points instead of the low melting acids that are obtained from the ammonium salt.

**Colorimetric determination of iron with kojic acid, M. L. Moss and M. G. MELLON.** (Purdue Univ.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 612-614, figs. 4).—Kojic acid (2-hydroxymethyl-5-hydroxy- $\gamma$ -pyrone) is unique as a reagent for iron in that no organic compound previously so used is a pyrone derivative. The sensitivity is sufficient to distinguish 0.05 p. p. m. of iron from a blank in 30-cm. Nessler tubes, and is adequate for quantitative determinations, especially with blue filters in a photometer. The color is relatively stable and conforms to Beer's law over a wide range. The chief limitation of the method is the necessity of controlling the acidity. A variation between pH 5.5 and 7.0 is permissible, and this range yields an orange hue suitable for visual comparisons. These limits are much wider than those for reagents such as ferron. Maximum sensitivity is obtained if the iron concentration is between 1 and 20 p. p. m. for a cell thickness of 1 cm. The color is somewhat less intense than that formed with thiocyanate or o-phenanthroline, thus permitting determinations on samples higher in iron than these other methods can accommodate without dilution. The method is not applicable to samples containing aluminum, citrate, oxalate, or pyrophosphate.

**Thiocyanate method for iron: A spectrophotometric study, J. T. Woods and M. G. MELLON.** (Purdue Univ.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 8, pp. 551-554, figs. 4).—From several hundred transmission curves the authors concluded that ammonium thiocyanate is preferable to thiocyanic acid as a color-forming reagent. Nitric acid is preferable to sulfuric or hydrochloric acid. With this acid Beer's law is followed through the pH range 1.2 to 1.5, but not in higher acidities. Many of the 57 diverse ions studied interfere. The sensitivity is increased approximately 100 percent by using a 60-percent acetone solution. This solvent also improves the stability of the color. A solution of two cobaltamine salts is an improved color standard except for slight fading after several months.

In general, the thiocyanate method is inferior to several others, especially those using o-phenanthroline,  $\alpha,\alpha'$ -bipyridyl, or mercaptoacetic acid.

**Determination of lead in biological material: A mixed color dithizone method, F. L. KOZELKA and E. F. KLUGHESKY.** (Univ. Wis.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 7, pp. 492-494).—A simplified mixed-color dithizone method is described. The treatment of the digest with sulfur dioxide reduces the iron, thereby preventing the decomposition of the dithizone, and it oxidizes the tin and hence inactivates one of the metals which combine with the dithizone under essentially the same conditions as lead. The method eliminates the necessity of removing the excess dithizone or preparing standard dithizone solutions. Consistent recoveries of  $\pm 1$   $\mu$ g. of lead are obtainable.

**Colorimetric determination of copper with ammonia: A spectrophotometric study, J. P. MEHLIG.** (Oreg. State Col.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 8, pp. 533-535, figs. 2).—The concentration of the ammonium hydroxide used for dilution must be carefully controlled because the ammonia solution absorbs light. The same concentration must be used for the standards as for the unknown solutions. A 3 M solution is recommended. The color system follows Beer's law. The color is stable in diffuse light for at least 6

weeks, and the use of a series of permanent standards is possible. The color reaction may be reproduced to a high degree of precision. Of 60 common ions, only a few, especially cobaltous, nickelous, and dichromate ions, seriously interfered with the color comparison. A considerable number of others caused precipitation or turbidity, but in the course of the determination this latter group would be removed.

**Titan yellow qualitative test for magnesium**, E. B. and C. E. OTTO. (Univ. Maine). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 1, pp. 65-66).—From a study of the influence of numerous ions and of variations in the conditions of the test the authors showed that the titan yellow test, although not specific for magnesium, is useful and efficient when properly applied. It is suitable for test tube or spot plate but not reaction paper. An improved spot plate procedure is given. A pH of about 12.5 is necessary for the production of the red color. Interference may be caused by ions which undergo a similar reaction, by ions which because of their color or that of compounds formed with hydroxide mask the magnesium-titan yellow color, or by ions which keep the pH too low. Ions which interfere, however, will be removed in the usual qualitative procedure before testing for magnesium and hence cause no trouble.

**A rapid versus a quantitative method for determining available magnesium in soils**, W. H. GAEMAN and F. G. MERKLE. (Pa. Expt. Sta.). (*Soil Sci.*, 53 (1942), No. 1, pp. 15-25, fig. 1).—Available magnesium was determined in 170 selected soil samples by a rapid and by a quantitative procedure for the purpose of comparing the accuracy of the two methods as applied to widely different soils.

The coefficient of correlation was  $0.80 \pm 0.08$ . For the 136 samples with less than 200 lb. per acre,  $r$  was  $0.87 \pm 0.02$ , and for the 34 samples with 200 lb. or more per acre,  $r$  was  $0.54 \pm 0.09$ . It was shown that the rapid method is fairly reliable in dividing soils into various levels of magnesium content and is sufficiently accurate to meet the needs for which rapid-test data are intended. In the hands of a dependable and experienced worker, it can be relied upon to divide soils into at least the four groups—low to very low, medium, high, and very high. The use of this method seems to be well within the range of chemical accuracy required to coincide with present knowledge as to availability, uptake, and need for magnesium.

**A wet combustion method for determining total carbon in soils**, N. A. CLARK and C. L. OGG. (Iowa State Col.). (*Soil Sci.*, 53 (1942), No. 1, pp. 27-35, fig. 1).—In the method here described, the total carbon in soils and in pure organic compounds can be determined in from 20 to 25 min. with a high degree of accuracy, avoiding the varying correction factor necessary in methods of the type devised by Schollenberger (*E. S. R.*, 58, p. 113). Oxidation of the carbon is accomplished by  $K_2Cr_2O_7$  in a mixture of  $H_2SO_4$  and  $H_3PO_4$ . Speed of oxidation is increased by addition of  $H_2O_2$ . The  $CO_2$  set free is measured by collecting it in an evacuated absorption flask containing  $Ba(OH)_2$  and by titrating the excess  $Ba(OH)_2$  with HCl. A glycerine solution replaces mercury as the confining liquid for the  $CO_2$ . Potassium iodide dissolved in the glycerine solution prevents the apparent increase in  $CO_2$  when chlorides are present. Results are low, however, if the chloride content is greater than 1 percent. Carbonates are removed by boiling a solution of 5 percent  $H_2SO_4$  with 5 percent  $FeSO_4$ , apparently without loss of organic carbon.

**Rapid estimation of base-exchange properties of soil**, A. MEHLICH. (N. C. Expt. Sta.). (*Soil Sci.*, 53 (1942), No. 1, pp. 1-14, figs. 3).—The author reports improvements in the barium hydroxide triethanolamine acetate method already described (*E. S. R.*, 83, p. 300). Barium chloride and triethanolamine neutralized

to pH 8.2 with HCl are now substituted for the hydroxide and acetate, respectively, to correct inaccurate titration end points caused by the buffer action of acetates at low pH values.

Ammonium nitrogen and nitrate nitrogen were separately determined by the methods devised at the Connecticut [New Haven] Experiment Station (E. S. R., 77, p. 302). The exchangeable magnesium was determined by the titan yellow method in an electrophotometer, and exchangeable calcium and potassium as the oxalate and cobaltinitrite, respectively.

**A rapid method for determining soil moisture, J. S. PAPADAKIS** (*Soil Sci.*, 51 (1941), No. 4, pp. 279-281).—Place 50 gm. of soil in a flask marked at about 100 cc. Add tap water, shaking at the same time in order to eliminate soil air. Make up to the volume, and weigh. Subtract from this weight that of the flask made up to the same volume with water alone. The oven-dry weight of the soil is the difference multiplied by a factor determined once for each kind of soil by oven drying a sample and dividing the oven-dry weight by the afore-mentioned difference. The factor varied from 1.563 to 1.667 for 17 soils tested; it is about 2.8 for wheat grains, 3 for maize grains, 2.73 for green wheat plants, 1.623 for kaolin, 1.639 for chalk, 1.612 for sand, and 1.618 for gravel.

**Methods for determining phosphate in soil extracts, I. A. BLACK** (*Soil Sci.*, 51 (1941), No. 4, pp. 289-298).—Organic matter was destroyed by permanganate and the iron precipitated as ferrocyanide. Iron and manganese could be completely precipitated by ferrocyanide at pH values between 1 and 2, a degree of acidity sufficient to prevent coprecipitation of any of the phosphate. Excess of ferrocyanide was removed by a sufficient addition of a 10-percent solution of manganous sulfate. A form of the original molybdenum blue method of Denigès (E. S. R., 44, p. 611) was then followed. When large quantities of titanium were present a further modified procedure involving isolation of a phosphomolybdate precipitate and re-solution of this in ammonia before color development became necessary. The titanium caused low phosphate figures in the simpler procedure.

**Spectrochemical analysis of trace elements in fertilizers: Boron, manganese, and copper, E. H. MELVIN and R. T. O'CONNOR** (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 8, pp. 520-524, figs. 4).—Using the low-voltage D. C. arc and a method involving a step sector and internal standard, the authors developed a procedure for the simultaneous determination of boron, manganese, and copper in mixed fertilizers with an accuracy of about  $\pm 5$  percent. Unavoidable background was found the greatest single source of inaccuracy. Preparation of base material to correspond to the average composition of fertilizers served to avoid error due to the effect of one ion on the excitation of another. The spectrochemical procedure can be used to supplement the chemical analysis of fertilizers for primary nutrients by providing a rapid method for determining the concentration of the essential trace elements.

**Spectrochemical analysis of trace elements in fertilizers: Zinc, R. T. O'CONNOR** (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 597-600, figs. 2).—The author devised a method for the spectrochemical determination of zinc in mixed fertilizers and applied it to the analysis of 44 representative mixed fertilizers of known chemical composition. The method is capable of determining zinc within the limits of 0.0002 percent (2 p. p. m.) to approximately 1 percent with an accuracy within  $\pm 5$  percent, thus equaling available methods for the determination of boron, manganese, and copper. The method involves the use of plates which have been treated with a special sensitized coating. The accuracy obtained shows that these plates are sufficiently consistent to permit quantitative determinations without appreciable sacrifice of

accuracy. Comparison of the values obtained by the spectrochemical method with those obtained by chemical analysis show that, in general, the chemical values are lower than the spectrochemical values, a discrepancy previously noted in similar comparisons.

**Determination of hydroxide in basic copper sulfates used as fungicides,** H. BOIS. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 24 (1941), No. 8, pp. 766-767).—This is an adaptation of the methyl orange titration method.

**Reducing power of starches and dextrins,** F. F. FARLEY and R. M. HIXON. (Iowa Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 616-617, figs. 2).—A rapid ferricyanide method for determining the reducing power of starches and dextrins in which the reduced iron is measured directly by a ceric sulfate titration is presented. For starches hydrolyzed by hot or cold acid or oxidized by alkaline hypochlorite, and for raw starches and dextrins, the reducing power values by this method parallel those determined by a more time-consuming procedure. Many other modified starches, such as the "chlorinated" and "thin-boiling" types, were studied.

**Determination of levulose in the presence of dextrose and sucrose: A ferricyanide method,** H. C. BECKER and D. T. ENGLIS. (Univ. Ill.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 1, pp. 15-18, figs. 2).—The reagent used contained 50 gm. of potassium ferricyanide, 225 gm. of disodium phosphate dodecahydrate, and 150 gm. of anhydrous sodium carbonate per liter. The oxidation was made at 50° C. for 60 min. Dextrose was found to exert a small but definite reducing action, and a factor is introduced to correct for its presence. Sucrose had very little effect on the determination, and large quantities did not interfere appreciably. When the levulose present was 20 percent or more of the total reducing sugar, an average accuracy of 0.5 percent was obtained. The error increased rapidly as the ratio of levulose to total reducing sugars decreased below this value.

**Role of velocity gradient in determining the cuprammonium fluidity of cellulose,** C. M. CONRAD. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 8, pp. 526-533, figs. 7).—In a study of methods of expressing the results of moderately to highly anomalous solutions, such as 0.5-percent cuprammonium solutions of undeteriorated cotton cellulose, the velocity gradient at which the measurement is made was found to be an important factor. The most promising procedure for anomalous solutions consists in obtaining fluidity or viscosity readings at several velocity gradients and then interpolating the results logarithmically to some common mean velocity gradient. Methods for varying the mean velocity gradient are suggested. A mean velocity gradient of 500 sec.<sup>-1</sup> is recommended as convenient of attainment in ordinary capillary viscometers and probably representative of gradients for which results of anomalous solutions have been recorded. The adoption of a common mean velocity gradient for expression of the results of anomalous solutions will not only eliminate instrument errors but will provide a unique value for any given substance. Methods are suggested for relating this to the molecular weight.

**The chemistry of menhaden oil: Component fatty acids,** W. H. BALDWIN and W. B. LANHAM, JR. (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 615-616).—Methyl ester fractionation and related procedures were applied to the analysis of an oil regarded as of current importance because it is the most abundant marine oil produced on our own Atlantic coast.

**Determination of peroxide values for rancidity in fish oils,** M. E. STANSEY (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 627-631, figs. 2).—The author points out that, inasmuch as rancidity has the two stages (1) peroxide formation and (2) formation of the compounds giving the rancid quality from

the peroxides, the quantity of peroxide present can be proportional to the degree of rancidity only so long as the peroxides are formed from the fresh oil at a rate greater than that of their decomposition to the rancidity compounds. He shows that the empiricism of this determination can be decreased, and the reaction made more nearly quantitative and less dependent upon experimental conditions, by the addition of strong mineral acids. Several other modifications in the conventional procedures are also suggested to improve precision.

**Estimation of gossypol in crude cottonseed oil**, J. O. HALVERSON and F. H. SMITH. (N. C. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 1, pp. 46-48).—Precipitation as dianilnogossypol dipyrindine is expedited by increased temperature, by the addition of gossypol in an ether-extracted oil prepared from cottonseed meats, and by constant agitation which precipitates the gossypol in a good crystalline condition for rapid filtration and washing without appreciable loss due to dissolving. Solubility is prevented by the use of pyridine in the wash solution. The gossypol compound is prevented from adhering to the glass container by the elimination of practically all water. Recovery of added gossypol and the reproducibility of results are good.

**Application of the refractometer to determination of the solids in milk products**, V. D. LUDINGRON (*Milk Plant Mo.*, 30 (1941), No. 12, pp. 32-34, 64-65, figs. 5).—Experiments were conducted with normal and condensed skim milk, normal milk and cream, sugared milk and cream (60 percent sucrose added), and washed sugared cream. Results are presented graphically. It was impossible to obtain satisfactory refractive index readings on the unaltered milk or cream because of the scattering of the light by the fat globules. Clear readings could be obtained on the sugared milk or cream, but total solids could be estimated with an accuracy of only about 0.9 percent, or 0.5 percent in the case of washed cream, which is not considered sufficiently precise for commercial use. Total solids in normal or condensed skim milk could be determined with a precision of about 0.2 percent.

**Composition of the ash of dry skim milk and its relation to neutralization**, F. HILLIE (*Jour. Assoc. Off. Agr. Chem.*, 24 (1941), No. 3, pp. 744-751, fig. 1).—Data are reported showing that the alkalinity of the water-soluble ash does not give a true measure of the sodium and potassium normally present in the ash. Part of the sodium added to milk as sodium lactate appears in the water-insoluble ash. The addition of calcium lactate caused an unsuspected increase in the alkalinity of the water-soluble ash. The alkalinity of the water-soluble ash, therefore, measures neither the total sodium and potassium present in milk ash itself nor the basic sodium or calcium compounds present in milk as a result of neutralization. The increase in total alkalinity above normal is, however, a good measure of the amount of such neutralizing compounds used.

**Rapid method for determination of manganese in feeds**, J. W. COOK. (Wash. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 1, pp. 48-50).—Essentially the sample is digested with nitric and perchloric acids. The insoluble residue is filtered off. The filtrate is diluted and oxidized with sodium periodate, and the permanganate formed is determined by colorimetric comparison with a standard solution of potassium permanganate of approximately the same concentration.

**Determining the maturity of frozen peas: A rapid objective method**, F. A. LEE. (N. Y. State Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 1, pp. 38-39).—The method proposed depends upon the determination of the specific gravity of thawed peas by means of the difference between the weight of the sample in air and the weight in a liquid, in this case a mixture

of xylene and carbon tetrachloride, the specific gravity of which is 1.000. Xylene alone can be used, but the calculations are less simple. The results showed practically the same degrees of correlation with the organoleptic tests as did those of the determination of alcohol-insoluble solids. The new method is less time consuming than are other procedures of like dependability. The following tentative standards are suggested: Fancy, sp. gr. 1.084 and lower; and standard, sp. gr. 1.085 to 1.094. Samples having a specific gravity of 1.095 and higher should be considered substandard.

**A clinical method for the determination of nicotinic acid in blood and urine.** E. STORTZ (*Jour. Lab. and Clin. Med.*, 26 (1941), No. 6, pp. 1042-1046, figs. 2).—The method described is a composite of several tested methods reported in the literature. It employs an acid hydrolysis of a tungstic acid filtrate, as suggested by Pearson (*E. S. R.*, 82, p. 86), using as a coupling amine *p*-aminophenol as in the Bandier and Hald method (*E. S. R.*, 82, p. 586) in an acid phosphate solution. Color development is measured either in the spectrophotometer or photoelectric colorimeter. The technic is described in detail for blood, and the necessary adaptation to urine is noted. Data from blood analyses, including the recovery of added nicotinic acid, "demonstrate that with the procedure described (1) a perfectly straight line relation was obtained between the log of the transmission at  $\lambda=400$  m $\mu$ , and the amount of nicotinic acid; (2) that in the development of the color the reaction is 95 percent complete in 40 min., and constant from 55 to 95 min. standing in the dark; (3) that in duplicate analyses of a single specimen of blood, results are reproducible within 6 percent; and (4) that in recovery experiments where the nicotinic acid (in normal saline) is added directly to the blood, never less than a 92-percent recovery was obtained in the range 3.0 to 15.0  $\mu$ g. of nicotinic acid."

**Quantitative determination of dissolved oxygen: Ascorbic acid oxidase method.** P. F. SHARP, D. B. HAND, and E. S. GUTHRIE. (Cornell Univ.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 598-597, figs. 2).—The authors found that the dissolved oxygen content of several fluids containing organic matter can be determined quantitatively by adding reduced ascorbic acid followed by ascorbic acid oxidase. The decrease in ascorbic acid as determined by titration indicates the dissolved oxygen content. Special oxygen-analysis tubes were designed to protect the liquid from air and avoid transference of the liquid during the determination. The method gave results in good agreement, in water analysis, with those of the Winkler method. The probable error was found to be from 0.1 to 0.2 p. p. m. It was found that one analyst can easily make 30 determinations in a half day if sufficient conveniently arranged equipment is available.

**The spectroscopic detection of vitamin E in the tissues of the rat.** T. MOORE and K. R. RAJAGOPAL (*Biochem. Jour.*, 34 (1940), No. 3, pp. 335-342, fig. 1).—The estimation of the vitamin was complicated by possible loss due to destruction by extraction treatments, particularly treatment with alkali for digestion and saponification, and by the interference of other substances not removed if the saponification procedure was omitted. By the method used (involving digestion and saponification) vitamin E was detected in the depot fat, but not in other tissues, of rats which had received much wheat germ oil over long periods. When large doses of *dl*- $\alpha$ -tocopherol or its acid were given to rats over short periods no evidence of storage of the vitamin in the tissues could be obtained. In some tissues, even from rats not receiving vitamin E, unidentified substances with an absorption band near the maximum for esterified tocopherol were present.

"In a few experiments the spectroscopic data were compared with results by the colorimetric method of Emmerie and Engel.<sup>1</sup> In the fat deposits, in qualitative agreement with the spectroscopic results, the vitamin was only detected in significant amounts in rats which had received wheat germ. In liver the amounts of vitamin E present according to the color test showed little variation with dietary history. Comparison with the spectroscopic data suggested that in liver substances other than tocopherol may have contributed to the color reaction."

**Studies of Florida and California oranges in regard to the relationship of frost damage to juice content**, L. M. BEACHAM (*Jour. Assoc. Off. Agr. Chem.*, 24 (1941), No. 3, pp. 788-793, fig. 1).—As a result of the studies conducted on Florida and California oranges it appears that a comparison between the juice content of the sound fruit in a given lot of oranges and the juice content of all the fruit present in the lot may be used for determining objectively the extent to which the lot has been injured by freezing.

**Boiling-point elevation of sucrose solutions**, C. J. TRESSLER, W. I. ZIMMERMAN, and C. O. WILLITS. (N. Y. State Expt. Sta.). (*Jour. Phys. Chem.*, 45 (1941), No. 8, pp. 1242-1245, fig. 1).—The authors found the boiling-point rise of 3.9° C., accepted by the maple sirup industry as showing a concentration of 11 lb. of sucrose to the gallon, not to agree with some of the recorded figures for the effect of this solute on the boiling point of water. Careful measurements showed that the values obtained for the boiling-point elevation of sucrose solutions varied considerably according to the method used in the determination. For the type of apparatus used the values presented are somewhat lower than those of other investigators, the boiling-point elevation for "standard" sirup being 3.8° C. (6.84° F.). In the actual preparation of maple sirup, deviations from this standard value may be expected, due for the most part to the fact that the thermometer is customarily read while it is dipping into the superheated boiling solution and also to the presence of certain amounts of invert sugar and substances other than sugar.

**The use of Iowa clays for the clarification of sorgo sirup**, W. G. GAESSLER, J. D. REID, and F. L. CUTBERT. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 15 (1941), No. 3, pp. 287-299).—Certain Iowa clays may be used to clarify sorgo juice for the production of sorgo sirup on the farm. Such sirup is equal to commercial products or better with regard to taste, clarity, and color. The process and a practical method of testing clays for their clarifying power is described. An exhaustive examination of two clays of very similar appearance, but of very different effect in the clarification of sorgo juice, showed that the principal difference was that the effective clarifying agent contained the clay mineral montmorillonite. Examination of a number of clays indicated that particle size was also an important factor in the practical use of the clay for clarification, since the clay must settle fairly rapidly after clarification. Clays suitable for this use are fairly widely distributed in Iowa. The loss of sirup in the clay clarification was about 6 percent. The saving in time and labor and the improved quality of the product amply compensate for this loss, however.

**The fructosan content of some grasses adapted to Iowa.—A preliminary survey**, A. G. NORMAN, C. P. WILSIE, and W. G. GAESSLER. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 15 (1941), No. 3, pp. 301-305).—The authors determined the fructose polysaccharides in some of the more important grass species adapted to Iowa conditions in order to ascertain whether any of these might serve as a source of fructose. In almost all samples the content was of the order of from 2 to 4 percent, which would not be sufficiently high for this purpose.

<sup>1</sup> Rec. Trav. Chim. Pays-Bas, 58 (1939), No. 7-8, pp. 895-902.

The largest quantity found, 7.6 percent, was in Sudan grass at the blooming stage.

**Levulose from chicory, dahlias, and artichokes**, E. S. HABER, W. G. GAESSLER, and R. M. HIXON. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 16 (1942), No. 2, pp. 291-297).—From results secured in tests for 2 yr., chicory appeared to be easier and cheaper to produce from the agronomic standpoint than are the other two plants named. The moisture content, percentages of levulose, glucose, and nitrogen, and the glucose-levulose ratio as found in a considerable number of samples of each of the three crops are tabulated.

**Anaerobic decomposition of wheat straw by thermophiles and the quantity of gas produced**, R. P. STRAKA, G. H. NELSON, and M. LEVINE. (U. S. D. A. coop. Iowa State Col.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 3, pp. 129-144, figs. 8).—Experiments on production of fuel gases (E. S. R., 81, p. 167), pulp, and fertilizer material from straw are described. Wheat straw produced 404 cc. of gas per gram of volatile solids when the straw was finely ground, 392 cc. when the straw was chopped to one-fourth of an inch, the corresponding figures for cornstalks being 543 and 401 cc., respectively. The gas produced contained between 55 and 60 percent methane and between 2 and 2.5 percent hydrogen, the greater part of the remainder being carbon dioxide. Percentage decomposition of cellulose and pentosans was high, no indication of selective fermentation being noted. There was also appreciable break-down of lignin, but this appeared the most resistant of the three types of component named. The formation of some lignonitrogenous complexes was indicated.

**Effect of metal containers on the anaerobic fermentation of cornstalk flour by thermophiles**, R. P. STRAKA and G. H. NELSON. (U. S. D. A. coop. Iowa State Col.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 1, pp. 19-31, figs. 5).—The fermentations in the stainless-steel container compared favorably with those in the glass control. The quantities of gas produced in these two containers were fairly close throughout five runs. The break-down of the various constituents, although it varied more widely than did the gas produced, was approximately of the same magnitude for the two containers. The cellulose and the pentosans were broken down the most readily; the lignin was the most resistant. Less gas was generally produced from the sheet-iron than from the glass container throughout five runs, but the relative quantities of gas produced from the sheet-iron container varied considerably from run to run. Less gas was produced in the sheet-iron container than in the glass, but the break-down of the various constituents was approximately of the same magnitude for both containers. Practically no gas was produced from the copper container throughout four runs. Decreasing quantities of gas were obtained from the galvanized-iron container, and a fifth run produced practically no gas. Greater quantities of the various constituents were broken down than could be accounted for by the gas produced throughout the runs in both the copper and the galvanized-iron containers.

**Relations between wheat malt dosage, flour diastatic activity, and gassing power**, F. C. HILDEBRAND and W. F. GEDDES. (Minn. Expt. Sta. et al.). (*Cereal Chem.*, 17 (1940), No. 5, pp. 626-635, figs. 3).—In adding to a common base flour varying levels of malted wheat flours which differed widely in amylase activity, gas production was found to vary directly as the logarithm of the malt-flour dosage, whereas the relationship between dosage and diastatic activity was best expressed by a quadratic equation. Estimation of malt-flour activity is most conveniently and simply made by plotting cubic centimeters of CO<sub>2</sub> produced by blends against the logarithm of dosage and the quantity of malt flour required to produce the selected level of gas production read from the straight

line thus obtained. The relation between diastatic activity and gassing power was curvilinear, although the substrate was essentially the same throughout.

**Activated carbon from certain agricultural wastes**, T. R. McELHINNEY, B. M. BECKER, and P. B. JACOBS. (U. S. D. A. coop. Iowa State Col.). (*Iowa State Col. Jour. Sci.*, 16 (1942), No. 2, pp. 227-239, figs. 3).—Carbons comparable with commercial carbons in adsorptive capacity were prepared from oat hulls, corncobs, pecan shells, and cornstalk pressboard. Figures for a carbon from straw show about three-fourths and for a carbon from rice hulls about one-half the capacity of the commercial carbons. If economically feasible, manufacture of activated carbons represents a potential outlet for utilizing large quantities of these agricultural waste materials.

**Microbiology of paper containers for fluid products**, E. WHEATON (*Inst. Food. Technol. Proc.*, 1 (1940), pp. 213-226, figs. 2).—Bacteriological methods for determining the sanitary quality of paper stock and finished containers and desirable bacterial standards for each are discussed. The significance of determining the presence of coliform organisms is stressed. A discussion by R. S. Breed (pp. 223-226) makes a plea for as much simplification of bacteriological methods in examining paper stock and paper containers as is consistent with reliable results.

**Economic losses due to the activities of microorganisms**, J. R. SANBORN and R. A. GILLOTTE. (N. Y. State Expt. Sta.). (*Paper Trade Jour.*, 112 (1941), No. 21, pp. 33-37).—The pernicious effects of micro-organisms in paper mill systems which result in slime, offensive odors, decreased production, inferior quality, and increased maintenance costs are most efficiently controlled by preventive measures, data on which are briefly presented. Thorough washups, sterilization of cleaned surfaces and equipment, and use of bacteriologically satisfactory water supplies are general precautions to follow, with specific germicides applied at points most favorable to microbial development.

**The spore germination of bacteria commonly found in paper and paper products**, [R. S.] BREED [*Tech. Assoc. Pulp and Paper Indus.*], *Tech. Assoc. Papers*, 23. ser., No. 1 (1940), pp. 72-73).—A discussion of the significance of spore-forming bacteria in pulp, paper, and paperboard products.

**Accuracy and significance of bacterial counts from paper and paperboard**, R. S. BREED and J. R. SANBORN. (N. Y. State Expt. Sta.). (*Paper Trade Jour.*, 113 (1941), No. 1, pp. 24-29, figs. 2).—Methodology, permitting a more accurate estimation of the bacterial numbers in paper and paperboard, is discussed at length.

**Production of naval stores** (U. S. Dept. Agr., *Misc. Pub.* 476 (1942), pp. 10, figs. 5).—This is a brief general outline of the industry, defining and explaining the term "naval stores" and briefly describing the collection and processing of the crude gum and the types of turpentine and rosinous products obtained by gum distillation, steam, sulfate, and destructive-distillation processes and listing the principal uses of turpentine and the rosins so obtained.

## AGRICULTURAL METEOROLOGY

**Meteorology** (In *Bibliography of the Virgin Islands of the United States*, edited by C. F. REID ET AL. New York: H. W. Wilson Co., 1941, pp. 131-132).—Twenty references are given.

**Meteorological observations**, [1941], C. I. GUNNESS ET AL. (*Massachusetts Sta. Met. Ser. Buls.* 625-636 (1941), pp. 4 each).—These are the usual summaries of observations for each month at Amherst, Mass., with brief notes on the more significant features.

The December number contains an annual summary for 1941, which shows that the mean pressure for the year was 29.997 in.; the mean temperature 48.5° F., as compared with the normal of 47.4°, highest 94° June 27, lowest —9° January 30; total precipitation 33.93 in., as compared with the normal of 43.7 in.; snowfall 42.5 in., as compared with the normal of 47.78 in.; mean cloudiness 49 percent, bright sunshine 68.2 percent; last frost in spring May 13, first in fall September 30; last snow April 17, first December 13.

**American Geophysical Union endorses the median as best expression of normal precipitation**, H. T. GISBORNE (U. S. D. A.). (*Jour. Forestry*, 39 (1941), No. 12, p. 1027).

**Trends in Kansas rainfall and temperature** (*Kans. State Bd. Agr. Bien. Rpt.*, 32 (1939-40), pp. 137-167, figs. 8).—The following papers are included in this symposium: What the Trends Are, by G. S. KNAPP (pp. 137-148); Their Significance in Crop Production, by R. I. THROCKMORTON (pp. 148-158) (*Kans. Expt. Sta.*); and Their Effect on Water Supplies, by M. H. DAVISON (pp. 158-167).

**Measurements of the fall-velocities of water-drops and raindrops**, J. O. LAWS (U. S. Dept. Agr., Soil Conserv. Serv., 1941, SCS-TP-45, pp. [3]+33, figs. 8).

**Big waters on little streams**, A. S. FRY (*Agr. Engin.*, 22 (1941), No. 12, pp. 424-426, figs. 5).—Results of local thunderstorms and local effects of storms of widespread hurricane type in high Appalachian valleys in North Carolina and eastern Tennessee are described. A thunderstorm of the summer of 1938 over Webb Mountain near Gatlinburg, Tenn., a storm of the same type occurring in late August of 1940 near Asheville, N. C., and a storm of hurricane origin which caused damage in the middle of the same month are chosen for detailed discussion. Scouring of cultivated lands bordering the normally small creeks and brooks along their higher parts and heavy illuviation of silt, rock, and other debris over the bottom lands were the principal forms of agricultural damage.

**Stream flow records of Pennsylvania, 1940** (*Pa. Dept. Forests and Waters, Stream Flow, Recs.*, 1940, pp. 207).—Brief discussions of stream gaging, precipitation, and ground water precede the actual records which take up the bulk of the volume.

**Temperature and life**, O. RAHN (*In Temperature—Its Measurement and Control in Science and Industry*. New York: Reinhold Pub. Corp., 1941, pp. 409-419, figs. 5).—This paper, presented at a symposium held in New York City November 1939, under the auspices of the American Institute of Physics with the cooperation of the National Bureau of Standards, National Research Council, and other organizations, is an analytical review (19 references) and general discussion, with particular reference to the laws of thermodynamics as applied to living organisms.

**On solar-constant and atmospheric temperature changes**, H. ARCTOWSKI (*Smithsn. Misc. Collect.*, 101 (1941), No. 5, pp. VI+62, figs. 33).

**Mathematical analysis of the significant factors in the hygrometric forecasting equation for Florida minimum temperatures**, J. W. MILLIGAN (*Amer. Met. Soc. Bul.*, 22 (1941), No. 10, pp. 385-389, fig. 1).—Most previous empirical formulas developed to aid in forecasting minimum temperatures have used either the elements of temperature or hygrometric relationships. The present approach to the problem (1) attempts to use the 1:30 p. m. observational data, and (2) uses the maximum soil depth temperature at the 6-in. level as one of the elements in constructing the formula, based on the assumption that the air temperature will vary directly with that of the soil and the amount of water vapor in the air. In this formula the dew point temperature and the soil temperature at 6 in. are considered interrelated factors in determining the minimum temperature on

the ensuing morning. Using the formula developed for determining the probable minimum for each morning over a period of time, it was found that the average error would have been 2.4° F.

**The influence of Lake Erie on local snows in western New York,** L. W. SHERIDAN (*Amer. Met. Soc. Bul.*, 22 (1941), No. 10, pp. 393-395).—This study of the conditions accompanying numerous local snowstorms was made with the idea that the results might aid in predicting their occurrence.

**Armistice Day freeze sets record damage,** T. J. TALBERT. (Univ. Mo.). (*Amer. Fruit Grower*, 61 (1941), No. 11, p. 8).—A brief account of damage to Missouri orchards, among which 8-to-14-year-old apple trees suffered most.

**Experimental data on the freezing of plants at the Lakeland Meteorological Laboratory,** L. G. PARDUE, JR. (*Amer. Met. Soc. Bul.*, 22 (1941), No. 10, pp. 383-385, fig. 1).—This is a preliminary report on experiments with potted tomato and pepper plants and weather instruments placed at 2-, 5-, 14-, 24-, 34-, and 43-ft. levels in a steel tower set in the lowest point of a "frost pocket" of several acres extent to obtain data on critical temperatures of dormant plants under field conditions. The percentage damage to these plants ranged from 0 at minimum temperatures of 32° and 31° F. to 100 percent at 27°.

**Our climate: Useful information regarding the climate between the Rocky Mountains and the Atlantic coast, with special reference to Maryland and Delaware,** J. R. WEEKS (*Baltimore: Md. State Weather Serv.*, 1941, 6 ed., pp. 66, figs. 44).—This edition of the publication previously noted (*E. S. R.*, 69, p. 177) is said to contain the first "degree day chart" (p. 18) for any State. The degree day is a unit that was developed by engineers to determine the amount of fuel required at any place for heating purposes during the cold season.

**Why phenology?** M. A. HUBERMAN. (U. S. D. A.). (*Jour. Forestry*, 39 (1941), No. 12, pp. 1007-1013).—The literature of phenology is summarized, and recent efforts are classified into three groups, viz, construction of calendars and charts without regard to meteorological factors, correlation of plant and animal activities with those factors, and application of the principles of bioclimatics based on geographic, climatic, topographic, and biologic factors. The methods of phenology are briefly described, some of the factors needed in organizing such studies are suggested, and, finally, because of the tremendous possibilities in the application of bioclimatics to numerous human and agricultural problems, it is urged that a national effort be made to develop a sound program of phenological studies as a basis for such application.

## SOILS—FERTILIZERS

[**Soil and fertilizer investigations of the Bureau of Plant Industry**] (*U. S. Dept. Agr., Bur. Plant Indus. Rpt.*, 1941, pp. 12-13, 28-31).—Fertilizer research is reported on the following: The production of phosphate fertilizer and hydrogen for ammonia by the substitution of steam for air in blast-furnace methods for treating phosphate rock, the development of a method of granulation of potassium chloride, and the status of the use of mixed and high analysis fertilizers, all by R. O. E. Davis.

Soil chemistry investigations are reported as follows: The boron content of different soils throughout the United States, a method for the determination of fluorine in soils, and the possibility of the use of hickory leaves as an indicator plant to determine the availability of certain trace elements, all by H. G. Byers.

Soil microbiology investigations are reported on the inoculation of winter legumes and the effect of certain minor elements on nitrogen fixation, by C. Thom.

Data on the soil surveys are reported by C. E. Kellogg.

[**Soil investigations by the Georgia Station**] (*Georgia Sta. Rpt. 1941*, pp. 28–52, 55–59, 100–102, 110–112, 148–153, figs 4).—Topics discussed are the acidity of Georgia soils, equivalent acidity or basicity of some common sources of nitrogen, sources of nitrogen for cotton (including pot tests on the availability of organic nitrogen), the use of limestone in mixed fertilizers, rates of potash for cotton in acid and neutral fertilizers, the use of broadcast limestone on cotton soils, fillers and supplements for cotton fertilizers, some results from the use of calcic limestone and various sources of nitrogen on a very acid Cecil sandy loam, the residual effect of nitrogen, effect of rainfall on movement of nitrates in the soil, evidence of the value of sodium in cotton fertilizers, sources of phosphorus, chemical soil tests, soil tests on pastures, and the work of the Southern Piedmont Soil and Water Conservation Experiment Station, Watkinsville, Ga.

**Preliminary color standards and color names for soils**, T. D. RICE, D. NICKERSON, A. M. O'NEAL, and J. THORP (*U. S. Dept. Agr., Misc. Pub. 425 (1941)*, pp. 12, pls. 8, figs. 6).—Descriptive designations of 56 colors covering the range of soil colors were chosen from among the Inter-Society Color Council and National Bureau of Standards color names (noted below). They are arranged on cards pivoted at one corner and provided with openings beside each color patch to permit determining the color most nearly matching that of a given soil. The accompanying text briefly discusses the principles of the set of color names to which reference has been made and of the literal-numerical designation of colors by means of the color solid.

**Central notations for ISCC-NBS color names**, D. NICKERSON and S. M. NEWHALL (*U. S. D. A. et al.*). (*Jour. Opt. Soc. Amer.*, 31 (1941), No. 9, pp. 587–591, fig. 1).—The authors present a condensed description of the verbal method of color designation now accepted as that of the Inter-Society Color Council and the National Bureau of Standards, and tabulates the Munsell notations of the central colors of the ranges covered by each of the respective designations. The objective aimed at was a system of color designation “sufficiently standardized to be acceptable and usable by science; sufficiently broad to be used by science, art, and industry; and sufficiently commonplace to be understood, at least in a general way, by the whole public.”

**The modern conception of soil and its relation to plant growth**, C. O. ROST (*Greenkeeper's Rptr.*, 7 (1939), No. 4, pp. 5, 6, 43; *abs. in Minnesota Sta. Rpt. 1941*, pp. 46–47).—The paper presents a general discussion of the modern concepts of soil formation in relation to climatic factors and the effect of these upon plant growth.

**The muck soils of Michigan, their management and uses**, P. M. HARMER (*Michigan Sta. Spec. Bul. 314 (1941)*, pp. [1]+128, figs. 76).—This publication presents a comprehensive account of the origin, distribution, classification, management practices, and cultural treatments for the production of various crops on muck soils. The muck soil area in Michigan is considered to be at least 4,000,000 acres in extent. Many farms throughout the State have been found to have areas of muck soil. The author points out that muck farming in Michigan is in its infancy, and that the main use of muck at the present time is for the growth of special crops. The development of new areas is likely to be in connection with the production of general crops.

Muck soils are classified on the basis of the reaction of the surface soil into the three following groups: (1) Low-lime mucks (pH 4.5 or less), (2) high-lime mucks (pH 7.0 to 4.6), and (3) alkaline mucks (pH 7.1 or higher). The need of Michigan muck soils for lime is considered, with a discussion of the need for liming in connection with the production of various crops. The value of

sulfur and of manganese sulfate on alkaline muck for securing satisfactory production is given for several crops based on 15 yr. of experimental results.

Nutritional disorders in muck crops, such as cracked stem of celery, girdle of table beets, and boron deficiency of sugar beets, are reported as being directly due to lack of available boron in Michigan muck soils. Application of 25 lb. per acre of boron is suggested as generally being sufficient to correct these deficiency diseases. In some cases, however, 100 lb. per acre of borax mixed in the fertilizer and well worked into the soil may be used safely. The response to copper sulfate was found to vary with different crops. Applications of salt have been found beneficial for certain crops. The author points out that from 500 to 1,000 lb. per acre of salt in addition to the regular fertilization can be recommended for newly reclaimed muck on which celery is to be grown. An annual application of from 250 to 500 lb. per acre is suggested as being sufficient on older celery fields.

The limitations of the moisture supply of muck soils are discussed in considerable detail. Recommendations are made on systems of drainage, water table level, ditches, dams, and tile locations. The harmful effects of burning muck land during clearing operations are emphasized. Extremes in temperatures of muck soils are considered in relation to frost injury, moisture supply, lakes, air drainage, location of heaters, decomposition, and several other important factors related to crop production. General problems on the use of fertilizers for muck crops are reported in detail, with recommendations as to the use of fertilizers for specific crops.

**The relative productivity of some humid subsoils, C. O. ROST. (Minn. Expt. Sta.).** (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 281-287, figs. 6; abs. in *Minnesota Sta. Rpt. 1941*, pp. 31-32).—The yield of oats on 14 soil profiles fell very rapidly from the surface downward. A nitrogen fertilizer usually remedied the unproductivity as effectively as did nitrogen and phosphate or nitrogen, phosphate, and potassium. Similar experiments with red clover and with sweet-clover are reported, the  $\frac{1}{8}$ - and  $\frac{1}{16}$ -ft. layers giving better yields than did the surface soil, whereas the lower layers showed decreased yields, usually remediable by phosphates or phosphates and potassium salts. On six fields with soil removed to depths varying from 5 to 25 ft. inoculated alfalfa grew satisfactorily without fertilizer treatment, although on only one field was the fertilizer entirely without effect. On the remaining five there was a slight effect.

**Pasture production as affected by type and chemical composition of the soil, N. O. PRICE, W. B. ELLETT, and H. H. HILL (Virginia Sta. Tech. Bul. 78 (1941), pp. 14).**—From analyses of soils under good and under poor sods, it is concluded that a soil should have the following percentages and milliequivalent amounts of plant nutrients present in order to produce a good pasture: Total nitrogen 0.200 percent or more, total carbon 2.50 percent or more, total phosphoric acid 0.200 percent or more, available phosphoric acid 50 lb. per acre or more, available calcium 1,000 lb. per acre or more, exchange capacity 15.0 m. e. or more, and base saturation 60.0 percent or more. The chemical analyses of the soils from the Appalachian region showed that they contain higher percentages of nitrogen, total carbon, and phosphoric acid, and are less acid than the soils from the Coastal Plain and Piedmont Plateau. The potash content of the soils was found to be present in the exchangeable form in larger quantities in those soils which produced good pastures than in those producing poor pastures. It is believed that poor pasture growth may be attributed to soil acidity, the lack of nitrogen, organic matter, phosphoric acid, and lime.

**Some soil changes resulting from drainage, H. B. ROE. (Minn. Expt. Sta.).** (*Soil Sci. Soc. Amer. Proc.*, 4 (1939), pp. 402-409, figs. 8; abs. in *Min-*

nesota Sta. Rpt. 1941, p. 44).—Studies of open-ditch drainage effects on Minnesota swamp forests show large reductions of harmful acidity and much stimulation of desirable bacterial action and of timber growth during the life of the trees. Good permeability was shown to be developed, through from 13 to 20 yr. of tile drainage, in originally tight silt and clay loam and marl soils in Minnesota and North Dakota. Total subsidence of cultivated peat in Minnesota is shown to be closely proportional to depth of drainage on an experimental tract on which the water level was controlled at various successive depths.

**Biological aspects of soil fertility**, W. NEILSON-JONES (*Jour. Agr. Sci. [England]*, 31 (1941), No. 4, pp. 379–411, pls. 3).—A detailed account of experimental studies of the causes of infertility in a heath soil at Wareham Forest is presented.

**Some factors affecting the nitrate content of an orchard soil**, O. A. BRADF and G. H. DRICKSON (*Sci. Agr.*, 22 (1941), No. 1, pp. 61–67, figs. 3).—Nitrate nitrogen and moisture determinations under various conditions of cultivation in an apple orchard are presented. The authors report a marked difference in the nitrate nitrogen content under different systems of cultivation. Under minimum cultivation, where seeding took place on May 15, and regular cultivation, which was seeded on July 15, there were found to be no appreciable differences in soil moisture. Cultivating the soil during May, June, and early July as compared with scraping the soil did not consistently increase or decrease the nitrate nitrogen or moisture supply.

**Retention by the soil of the nitrogen of several amino acids**, J. P. CONRAD (Univ. Calif.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 1, pp. 48–58, figs. 3).—Since protein material added to the soil is largely made up of amino acids and also since amino acids are intermediate products in the break-down of protein material, the author points out the importance of a knowledge of the break-down of amino acids in the soil.

Preheating the soil to inactivate any enzymes or other thermolabile catalysts had only a slight effect upon the ability of the soil to remove amino acids from percolating solutions. Adsorption isotherms of a number of the more soluble amino acids with preheated Yolo fine sandy loam soil showed that the dicarboxylic monoamino acids, aspartic and glutamic, were most weakly adsorbed, the monocarboxylic monoamino acids, glycine, alanine, leucine, and norleucine, were somewhat more strongly adsorbed, and the monocarboxylic amino acids with one or more nitrogen-containing radicals in addition to the  $\alpha$ -amino radical, such as lysine, histidine, and arginine, were most strongly adsorbed—even more strongly so than the  $\text{NH}_4$  ion of  $\text{NH}_4\text{Cl}$ . Increased adsorption of amino acids was indicated by lengthening the hydrocarbon chain in the amino acids or transferring the  $\text{NH}_2$  radical farther out on the chain away from the carboxyl group. Replacing a hydrogen on the terminal carbon atom of the chain with a phenyl group was found to decrease adsorption, while an OH substitution increases the adsorption some and an SH substitution increases it somewhat more.

**Influence of orchard soil management upon the infiltration of water and some related physical characteristics of the soil**, L. Y. LI, R. D. ANTHONY, and F. G. MERKLE (Pa. Expt. Sta.) (*Soil Sci.*, 53 (1942), No. 1, pp. 65–74, figs. 11).—Cultivation in the fall and spring with an annual cover crop of rye sown in the fall and millet in the spring permitted soil deterioration, as evidenced by a reduction in the organic content, the granule stability, and the probable permeability. A more compact, easily dispersed surface layer resulted, giving rise to poorer infiltration and greater erosion and run-off. Alfalfa sod harrowed only in the spring resulted in higher organic content, better structure, increased infiltration, and decreased run-off and erosion. A permanent bluegrass sod harrowed each spring gave the highest organic content and the greatest

structural stability and permeability in the surface 3-in. layer, resulting in excellent infiltration and almost no run-off and erosion. The cumulative effects of these treatments from 1926 to 1940 resulted in a better moisture status in the entire soil mantle where perennial cover crops were used. There was shown to be a close correlation between changes in the physical properties brought about by variations in treatment and the actual measurements of moisture infiltration, run-off, and moisture content in the profile.

**Air and soil temperatures in a California date garden, D. E. BLISS, D. C. MOORE, and C. E. BREAM.** (Calif. Citrus Expt. Sta.). (*Soil Sci.*, 53 (1942), No. 1, pp. 55-64, figs. 4).—The temperatures of the air and of the soil at 1- and 3-ft. depths were recorded continuously by thermographs, and weekly mean temperatures were calculated from the thermograph charts by means of a planimeter. Temperatures of soil at depths of 4, 6, 7.5, and 8 ft. were determined weekly with standard thermometers. Wide seasonal variations in weekly mean air temperatures were found. During the summer months the temperatures of the air were considerably higher than those of the soil at a depth of 1 ft. The large palms which surrounded the instruments had a tempering effect on the air temperatures within the garden, but the mean weekly air temperatures were almost identical with those at a nearby meteorological station located in the open. Overturns in the temperature of the soil at different depths occurred regularly in the fall and spring of each year. The yearly range of air temperatures was considerably greater than that of soil at a depth of 1 ft.; the yearly range of soil temperatures diminished with increasing depth of soil.

**Report of the Chief of the Soil Conservation Service, 1941, H. H. BENNETT** (*U. S. Dept. Agr., Soil Conserv. Serv. Rpt., 1941, pp. II+75*).—This report emphasizes the role of the activities of the Soil Conservation Service during the past year in connection with the national defense effort. The defense activities have been summarized as follows: (1) Acquiring lands needed by the Army and Navy for camps, proving grounds, and other military purposes; (2) making lands available to the Army for defense purposes; (3) preparing aerial maps, drawings, blueprints, and other reproductions for defense purposes; (4) processing photographs for defense information purposes; (5) training personnel; and (6) providing various kinds of assistance in response to particular requests from defense agencies. The progress of the year is indicated by the increase in soil conservation districts from 314 at the beginning of the year to 548 at the end of the year—from an area of 190,163,351 to 332,088,660 acres. The number of districts cooperating with the Department of Agriculture almost doubled—from 224 to 439—in the same 12 mo. The specific progress in the various areas is presented by a review of the work in the several soil conservation regions of the United States. Progress on surveying and mapping, nurseries and range lands, wildlife, engineering structures and operations, stubble mulch, crops and cropping practices, pasture improvement, and several other activities related to the development of sound conservation practices is summarized. The importance of the research activities in the development of better soil conservation practices is emphasized, and some of their findings are briefly set forth.

[**Soil conservation and land use studies**] (*U. S. Dept. Agr., Sec. Agr. Rpt., 1941, pp. 176-182*).—This report takes up the great costs incurred through soil losses, the preparation of land-use-capability maps, and tillage by conservational methods. Control of floods by land treatments is also dealt with, an appraisal of benefits is made, and the national defense aspect is discussed.

**Water conservation on the Great Plains, F. C. FENTON.** (Kans. State Col.). (*Agr. Engin.*, 22 (1941), No. 2, pp. 45-46, 48, figs. 5).—Conservation of rain-

fall in an area in which the subsoils are dry and plant growth must depend upon the moisture content of the top 4 or 5 ft. of soil is discussed. Basin listing is highly effective, and in some sections of the Great Plains it is an established tillage practice. It is subject to the objection that the basin-forming attachment, added to an ordinary lister, increases draft by about 25 percent, and that for weed-killing tillage either the dams must be broken out or the ridges must be split and new furrows and dams made. On the other hand, a high degree of effectiveness is indicated by such examples as that of a basin-listed field at the Fort Hays Substation which held all of a rainfall of 2.5 in. in 30 min. on a 4-percent slope, while ordinary listing held less than one-half of this rainfall. At the Colby Substation basin listing resulted in 20-in. penetration as against 10-in. penetration on an unlisted field. The value of terracing and contour farming, strip cropping, and pasture furrows on contour are also noted. The value of storage ponds is emphasized, and the construction of many is noted. It is pointed out, however, that evaporation rates (in 1934, 70.5 in. at Garden City and 66 in. at Hays) are such as to require deep ponds for holding water through dry periods. A rule of current application is that of a depth equal to twice the annual evaporation loss.

**Soil conservation in Puerto Rico and the Virgin Islands of the United States: A handbook** (U. S. Dept. Agr., Soil Conserv. Serv., 1941, Region 2, pp. 141, figs. 39).—A comprehensive handbook of possible methods that may be employed in conserving the soils of Puerto Rico and the Virgin Islands.

**Soil erosion in China**, T. M. TIEH (*Geog. Rev.*, 31 (1941), No. 4, pp. 570-590, figs. 17).—The subject is discussed as to climate, soils, and vegetative cover, and the extent of soil erosion and its control.

**Dispersion studies on Gezira soil**, T. N. JEWITT (*Jour. Agr. Sci. [England]*, 31 (1941), No. 4, pp. 466-478, figs. 5).—The relation of initial moisture content to the degree of dispersion on shaking of the heavy clay Gezira soil is given. A minimum dispersibility was found at about 7 percent of initial moisture content. The relation between dispersion and water content is discussed in connection with possible effects in field practice.

**A private land rehabilitation and soil conservation program**, G. B. DE-WEESSE (*Agr. Engin.*, 22 (1941), No. 9, pp. 327-328).—The author describes measures of the usual type taken by a life insurance company to control sand and water erosion, to conserve moisture, and to improve fertility on farms securing agricultural loans. A number of instances of marked increase in the operator's returns from the farm resulting from such land improvements are noted. The company cooperates in the establishment of conservation districts.

**Application of the erosion equation to strip crop planning**, R. W. GERDEL and R. E. ALLEN. (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 2, pp. 59-61, 64, figs. 5).—An erosion equation by which the expected soil loss from any given cultivated strip in a strip-cropped field may be calculated for a large number of soil types in the Ohio Valley region is given in the form  $X = C.S^m$ , in which  $X$  represents soil loss in tons per acre from any given cultivated strip,  $C$  a constant or variation for soil group or soil type based upon erodibility,  $S$  is slope of the watershed in percentage, and  $m$  is an exponent which varies by length of watershed. Plotting the values for  $m$  against length of watershed produced a tangent curve with the center of moment about the values  $m = 1.91$ ; length = 250 ft. The equation for this curve is

$$m = 1.91 + 0.61 \left[ \arctan \left( \frac{L - 250}{100} \right) \right].$$

making a determination of  $m$  simply a matter of the insertion of the length of the watershed. Use of this equation and selection of arbitrary maximum soil

losses permits the determination of placement of diversion ditches on long slopes which are to be strip cropped. It is believed probable that this erosion equation, with only slight modification, can be applied to a considerable area of the country. For practical use, suitable charts or tables may be prepared from the basic equation.

**The design of plot experiments for measurement of run-off and erosion,** A. E. BRANDT. (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 12, pp. 429-432, 436).—In this factorially arranged control plot experiment, the main effects of the three variables are measured with the same precision as though the entire experiment had been devoted to each, and the possible interactions between them are measured with full precision. "If a research worker should attempt to answer all of these questions by letting but one factor vary at a time he would be lost in a maze of experiments." The principles involved in the design of such an experiment and the successive steps of its development are discussed in some detail.

**Surface run-off and erosion from permanent pastures in southwest Virginia as influenced by applications of triple superphosphate,** W. H. DICKERSON, JR., and H. T. ROGERS (*Virginia Sta. Tech. Bul.* 77 (1941), pp. 26, figs. 13).—The investigations reported cover data on soil and water losses from representative unimproved permanent pastures in southwest Virginia and the effect of pasture improvement through the use of triple superphosphate on soil and water losses. Rainfall characteristics, type and density of vegetative cover, and various soil properties were investigated to evaluate the effects produced. Soil and water losses are reported for several different locations under different degrees of slope for the Dunmore and Westmoreland soils. Soil loss from pasture plats was small, although the improvement in vegetation was accompanied by a significant reduction in the amount of soil removed by run-off. There was less erosion from the fertilized than from the untreated areas. Run-off from phosphated sods contained twice as much phosphorus as that from untreated areas. Changes in vegetation which were brought about by phosphating had no effect on water losses. It is pointed out that 7 of the 12 fertilized plats gave less run-off than the adjacent untreated plats, but that 5 other fertilized areas yielded more run-off than corresponding unfertilized areas. Areas with relatively good vegetative cover were found to lose between 10 and 20 percent of the rainfall as run-off during seasons which were followed by periods of insufficient moisture for producing good pasturage. Degree of slope of land and amount of run-off showed no definite relationship. There was no evidence of excessive soil loss on slopes up to 40 or 50 percent where a fair density of vegetative cover was maintained on the two soil types under study.

**The effect of mulching and methods of cultivation on run-off and erosion from Muskingum silt loam,** H. L. BOEST and R. WOODBURN. (U. S. D. A. and Ohio Expt. Sta.). (*Agr. Engin.*, 23 (1942), No. 1, pp. 19-22, figs. 2).—It was found that approximately the same degree of erosion control was afforded by mulches supported 1 in. above a sealed plat as on the surface. Elimination of raindrop impact, with its destructive effect on the soil surface, rather than the reduction of overland flow velocity appeared, therefore, to be the major contribution of the mulch. Soil concentration in the run-off increased sixfold when supported mulch was quickly removed during a run.

The effect of cultivation on erosion from a bare surface was measured by preparing plats at their moisture levels—rather damp, dry, and optimum for fine cultivation. The soil prepared at optimum moisture content sealed earlier than the others and suffered both the greatest run-off and the highest average soil loss. The dusty plats also had high run-off and soil loss. The average

run-off from the three plats, cultivated damp and left cloddy, was only 25 percent, and erosion was about one-fifth of that from the plats cultivated at optimum moisture content.

**Dynamics of water erosion on land-surfaces**, L. SCHIFF and R. E. YODER (U. S. D. A. and Ohio Expt. Sta.). (*Amer. Geophys. Union Trans.*, 22 (1941), pt. 2, pp. 287-298, figs. 3).—This paper covers a discussion of the factors involved in the surface movements of water on a watershed, the forces exerted by these water movements, the physical processes of erosion resulting from the forces, and the resistance of soil and vegetation to the movements and forces. Results and field observations from several workers are presented to emphasize certain important factors.

**Crops and dams protect a watershed**, E. WOLFE. (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 2, pp. 62-64, figs. 4).—A conservation and flood-control project in the McGregor watershed of 2,250 acres in northeastern Iowa, bordering the Mississippi River, is reported upon. The town is subject to frequent flood damage, and gully erosion on farms in the watershed has become serious, the cultivated land having lost about 60 percent of its topsoil, leaving a mixture of topsoil and subsoil which is easily eroded and has not the water-holding capacity of the original surface layer. Soil-saving crops and detention dams have been made the primary defensive measures. Some further work desirable to enhance the protection of the watershed is discussed.

**A study of factors affecting the stability of soil aggregates**, C. O. ROST and C. A. ROWLES. (Minn. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 421-433, figs. 5; abs. in *Minnesota Sta. Rpt.* 1941, pp. 32-33).—It was found that the dispersion and erosion ratios qualitatively separated soils differing markedly in erodibility into two groups. The erosion ratio served the better as an index for classifying the soils. Cultivation of the forest soils made them more susceptible to erosion than they were in their natural condition by increasing the amount of silt and clay which would disperse in water. Cultivation was found to have produced little change in dispersion in prairie soils. Under Minnesota conditions the results indicate that cultivated soils with dispersion and erosion ratios of less than 19 may be expected to be resistant to erosion and that those with dispersion ratios greater than 19 and erosion ratios greater than 30 will be susceptible to erosion. In uncultivated soils the separation is not as clear, but it would appear that if an uncultivated soil had an erosion ratio of more than 20 it would be susceptible to erosion when cultivated. A number of other observations relating to aggregation and erodibility are recorded.

**Laboratory experiments on evaporation from fallow soil**, H. L. PENMAN (*Jour. Agr. Sci. [England]*, 31 (1941), No. 4, pp. 454-465, figs. 3).—Evaporation from freely drained soils is considered in relation to the following conditions: (1) Isothermal conditions, in which, apart from surface cooling produced by evaporation, the soil is kept at air temperature; (2) evaporation under simulated summer field conditions, in which the soil surface is maintained at a higher temperature than the air for part of the day; and (3) the effect of dissolved salt in the soil water under both isothermal and nonisothermal conditions.

**Leaf analysis and plant nutrition**, G. W. CHAPMAN (*Soil. Sci.*, 52 (1941), No. 1, pp. 63-81, fig. 1).—After drying of the leaves selected for analysis the midribs were removed and the material was ground to pass a 40-mesh screen. Nitrogen was determined by a micromethod. Ashing for potassium and phosphate determinations was done in stainless steel dishes at barely red heat. Phosphate was determined by a molybdate colorimetric method and potassium by a rapid cobaltinitrite method.

From the results of a series of field experiments, the leaf composition and growth rate of seedling rubber are shown to be correlated. In mature rubber, similar relations exist. Latex yield is shown to be correlated especially with leaf nitrogen, and under certain conditions both are depressed by phosphatic fertilization. The effect of phosphates on the penetration of ammonia nitrogen into the soil is shown to be very marked. This is held to support the theory that the depression of nitrogen absorption by phosphatic fertilization is primarily a soil phenomenon.

**Applying fertilizer in liquid form, V. A. TIEDJENS.** (N. J. Expt. Stas.). (*Agr. Engin.*, 22 (1941), No. 12, pp. 440, 442).—Fertilizers in solution are likely to be more quickly available than when in solid form, especially when soil moisture is inadequate, and less wasteful, especially with respect to phosphates, of which more than the actual plant requirement is usually applied because of the low solubility of the phosphate in dry fertilizers; local excess concentrations and consequent burning can be avoided more readily with dissolved than with solid fertilizers; and uniform application of small quantities of the materials of poor physical characteristics (as stickiness) is easier. On the other hand, dissolved fertilizer salts can not contain much calcium and magnesium and will render the soil acid unless pulverized limestone is freely used; and excess must be avoided as with fertilizer applied in the solid form. Examples of striking economies coupled with markedly increased yields are noted.

**The effect of certain nitrogenous fertilizers on the chemical and vegetative composition and yield of pasture plants, J. F. EHEART and W. B. ELLETT** (*Virginia Sta. Tech. Bul.* 75 (1941), pp. 44, figs. 6).—In 9 years' tests on hay and grass plats with sodium nitrate, ammonium sulfate, and urea as sources of nitrogen, 200 lb. (one-half in April, one-half in July) of the nitrate nitrogen gave a greater increase in total quantity of grass dry matter and protein and in protein percentage than did the other two nitrogen sources. The results obtained in the experiments with ammonium sulfate and urea were insignificant. In hay, all three sources gave large increases, that from the urea being somewhat the greatest. Sodium nitrate gave the largest increase in ether extract and in crude fiber at an early cutting. Sodium nitrate and ammonium sulfate increased total digestible nutrient content more than did urea. All three sources of nitrogen decreased the percentage of clover and increased that of bluegrass. From a practical viewpoint, however, it was concluded that no significant improvement in composition or increase in yield of pasture vegetation was obtained from 50 lb. of nitrogen per acre from any of the three sources, and that the increases obtained from the larger dosages were not sufficient to pay their cost.

**Delta fertilizer studies emphasize need for nitrogen, R. KUYKENDALL** (*Miss. Farm Res.* [*Mississippi Sta.*], 5 (1942) No. 1, pp. 1, 8).—Effects of nitrogenous fertilizer on the cotton crops when applied for some years from various sources and on various soil types are tabulated, and some of the general tendencies are indicated.

**The determination of the total fixed nitrogen content of power plant flue gases, O. R. SWEENEY, F. E. CAMPBELL, and B. JONES.** (*Iowa State Col.*). (*Iowa State Col. Jour. Sci.*, 16 (1942), No. 2, pp. 207-210).—Pointing out that if all the fixed nitrogen in the coal burned annually could be recovered as ammonium sulfate it would amount to 32 million tons, or as sodium nitrate 40.5 million tons, the authors report analyses of flue gases from two boiler-heating furnaces, any nitrogen oxides in the gas samples having been reduced and the total combined nitrogen determined as ammonia. When the heating plants were operating at the higher temperatures the combined nitrogen of the flue gases decreased as the gases passed through the stack. This did not occur at the lower operating tem-

peratures. In no instance did the combined nitrogen exceed 0.1085 percent of the total available in the coal.

**The use of radioactive elements for soil and fertilizer studies**, W. J. HENDERSON and U. S. JONES. (Purdue Univ.). (*Soil Sci.*, 51 (1941), No. 4, pp. 283-288, figs. 4).—The fixation of phosphorus by Cecil clay, Bedford silt loam, Newton sandy loam, and Crosby silt loam was investigated by the use of the radioactive isotope. When  $\text{Ca}(\text{H}_2\text{PO}_4)_2$  containing radioactivated phosphorus was applied to the surface of the soil and washed down with water equivalent to a precipitation of  $2\frac{1}{2}$  in. the penetration of the phosphorus ranged from  $1\frac{1}{4}$  in. for Cecil clay to about 4 in. for Crosby silt loam. The addition of KCl caused the radioactive phosphorus to penetrate more deeply, but  $(\text{NH}_4)_2\text{SO}_4$  had no immediate effect. The radioactive technic was used to study the movement of potassium in Bedford silt loam. It was found that not more than 5 percent of the KCl applied penetrated beyond  $1\frac{5}{8}$  in. with a water treatment equivalent to  $2\frac{1}{2}$  in. of rainfall. The radioactive technic appeared to offer a valuable method for studying the behavior of ions in soils.

**Phosphate applied in narrow bands for better results**, R. COLEMAN (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 1, p. 7).—Placing the phosphate 2.5 in. to the side and 2 in. below the seed either in narrow bands or by hill dropping gave much better results for cotton than did any less concentrated placement in experiments, 1939-41. A badly eroded Atwood sandy loam was used in the 1939 test, and Paden silt loam in those of 1940 and 1941.

**Evidence in support of a new concept as to the end product of superphosphate in limed soils**, W. H. MACINTIRE and B. W. HATCHER. (Tenn. Expt. Sta. et al.). (*Soil Sci.*, 53 (1942), No. 1, pp. 43-54).—The conclusions detailed are very similar to those already noted in Tennessee Station Bulletin 176 (E. S. R., 85, p. 593). Supporting evidence from experiments with calcium fluoride introduced in quantities equivalent to the usual calcium silicate slag treatments is added. These increments of fluorides did not repress the uptake of  $\text{P}_2\text{O}_5$  supplied as dicalcium phosphate, but they repressed substantially the uptake from corresponding incorporations of tricalcium phosphate. It is concluded that any superphosphate not "fixed" and not used by the plant in a prelimed soil will suffer ultimate reversion to the fluorophosphate that characterizes raw rock. "Although the formation of this ultimate phosphatic compound in mixtures outside the soil has been demonstrated and indicated by plant cultures as occurrent within limed and phosphated soils, the extent to which the phenomenon may become of practical importance is to be established."

**Phosphorus fixation by soil separates and fractions**, A. T. PERKINS, C. E. WAGONER, and H. H. KING. (Kans. Expt. Sta.). (*Soil Sci.*, 53 (1942), No. 1, pp. 37-41).—Phosphate fixation was studied in separates and fractions of a Wabash soil ranging from fine sand to clay and obtained by sedimentation and bromoform flotation. Both the chemical composition of the soil minerals and the phosphate fixation were found related to particle size. As the particle size decreased, the  $\text{SiO}_2/\text{R}_2\text{O}_3$  ratio decreased and phosphate fixation decreased on a surface area basis but increased on a weight basis. These changes were gradual, until at a diameter of 0.006 mm. there was an abrupt change in the characteristics of the soil particles.

**Phosphorus fixation in relation to the iron and aluminum of the soil**, W. H. METZGER. (Kans. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 33 (1941), No. 12, pp. 1093-1099, fig. 1).—This article presents further evidence indicating that the relatively easily extractable iron and aluminum play an important role in phosphorus fixation. Based upon results from a previous paper (E. S. R., 84, p. 301), as well as on the results of the current investigation, the author concludes

that the phosphorus-fixing capacity under field conditions of acid soils of the Prairie group, and probably other groups of acid soils as well, can be very largely accounted for by precipitation phenomena, while fixation at particle surfaces in a replaceable form is of slight practical significance.

**Determination and behavior of ferrous iron in soils, V. IGNATIEFF** (*Soil Sci.*, 51 (1941), No. 4, pp. 249-263).—Extraction of ferrous iron without reduction of ferric iron to the ferrous state was shown to be accomplished by the use of 3 percent aluminum chloride solution. Of the ferrous iron present in a glei soil, this reagent extracted 80 percent in the first, 12 percent in the second, and 4 percent in the third extraction. Two more extractions removed 2 percent each. Determination of the extracted iron was made colorimetrically by means of the red dipyriddy complex. The determination had to be completed in the field. Large percentages of change in ferrous iron content took place from the time of sampling to that of a second determination in the laboratory 48 hr. later. Most samples lost ferrous iron by oxidation, but a very moist peat showed reduction of ferric to ferrous iron.

By the use of this method it was found that well-drained, healthy soils investigated contained very small quantities of ferrous iron. In some samples the presence of the divalent iron was not detected. Under waterlogged conditions large quantities of ferrous iron were produced rapidly, after an initial lag of 2 or 3 days. This is mainly a biological process. The soil ferrous iron is not readily brought into solution by water, but by the use of salts the ferrous iron can be displaced from the soil. Aluminum chloride proved to be the most efficacious for this purpose. This would indicate that ferrous iron enters into the base-exchange complex of soil. Under anaerobic conditions soil water could bring into solution quantities of ferrous iron, but much larger amounts of the divalent iron were held by the soil base-exchange complex. The Eh values indicate that the activity of the reducing agents present in waterlogged soil is greater than the reductive activity of ferrous iron. Ferrous iron in soil becomes readily oxidized if aeration of the soil is improved. Ferrous iron is formed when soil is steam sterilized, and some of this divalent iron persists in the soil for a considerable length of time. Sunlight facilitates the reduction of iron in some soils and soil extracts. There is a possibility that iron acts as a catalyst, and sunlight as a source of energy in the oxidation processes in soils.

**Inspection and analysis of commercial fertilizers, B. D. CLOANINGER** (*South Carolina Sta. Bul.* 336 (1941), pp. 177, figs. 4).—The 1940-41 inspection data are presented, with the customary analyses.

## AGRICULTURAL BOTANY

**Standardized plant names** (*Harrisburg, Pa.: J. Horace McFarland Co.*, 1942, 2. ed., rev. and enl., pp. XVI+675).—This revised edition (E. S. R., 53, p. 122) is discussed editorially on page 722.

**Abstracts of the papers presented before the Pacific section of the Botanical Society of America, Seattle, Washington, June 18 to 21, 1941** (*Amer. Jour. Bot.*, 28 (1941), No. 8, pp. 726-731).—The following are of interest to agricultural botany: Cytological Studies on the Carotene in the Root of *Daucus carota*, by T. E. Weier (p. 726) (Univ. Calif.); An Hereditary Variegation in Tomatoes Associated With Sterility, by J. W. and M. M. Lesley (p. 727) (Calif. Citrus Expt. Sta.); Natural and Experimental Polyploidy in *Solanum douglasii* Dunal and Its Relatives, by E. F. Paddock (p. 727) (Univ. Calif.); Anatomy of the Lima Bean, by R. S. Snell and L. H. Pollard (pp. 727-728) (Utah State Agr. Col.); Physiological Effects of Ethylene Chlorohydrin on Germination of Potato

Tubers, by H. D. Michener (p. 728); Development of the Vascular Network in the Node of *Ricinus communis*, by M. E. Reynolds (p. 728) (Univ. Calif.); Influence of Certain Desert Shrubs on the Occurrence of Annual Plants, by F. W. Went (p. 729); and Germination of California Native Seeds, by C. B. Wolf (p. 729).

Entering a new epoch, N. I. VAVILOV (*Chron. Bot.*, 6 (1941), No. 19-20, pp. 433-437).—This is a reprint from the chapter entitled The New Systematics of Cultivated Plants from the book previously noted (E. S. R., 83, p. 595).

The economic importance of seaweeds, L. B. MOORE (*New Zeal. Dept. Sci. and Indus. Res. Bul.* 85 (1941), pp. 40, figs. 19).—Following a general introductory section, the subject matter is taken up under uses of seaweeds (for manure, food, as sources of potash, iodine, agar, etc.), and New Zealand seaweeds of potential economic importance, with a key to the brown algae of that region. A glossary and 31 references are included.

Three new species of *Muhlenbergia*, C. O. GOODING (*Jour. Wash. Acad. Sci.*, 31 (1941), No. 12, pp. 504-506).

Species Batorum: The genus *Rubus* in North America.—IV, Verotriviales, L. H. BAILEY (*Gentes Herbarum*, 5 (1941), No. 4, pp. 199-228, figs. 14).—Technical descriptions are presented of a number of species of *Rubus* occurring in North America north of Mexico (E. S. R., 86, p. 301).

Effects of certain micro-ecological factors on the germinability and early development of *Eurotia lanata*, J. W. HILTON (*Northwest Sci.*, 15 (1941), No. 4, pp. 86-92, figs. 3).—Many desert ranges of the United States are rapidly becoming denuded of their usable forage plants. Of considerable import among them is *E. lanata*, the stability of which is seriously threatened in many areas. An understanding of the basic function of the factors influencing germination is essential to eventual restoration of this valuable forage plant. Toward this end studies are briefly reported on such factors as imbibition, effect of storage on seed, dormancy, temperature extremes and optimums, salt effects, early root development, and effects of bracts and pericarp on germinability.

Bibliography of the botany of New York State, 1751-1940, I, H. D. HOUSE (*N. Y. State Mus. Bul.* 328 (1942), pp. 174).

A checklist of plants in the Washington-Baltimore area, F. J. HERMANN (*Washington, D. C.: Conf. Dist. Flora*, 1941, pp. [1]+114).—This check list, containing about 2,170 species, varieties, and forms, is intended as an aid in the preparation of a new flora of this area to replace the now out-of-print flora previously noted (E. S. R., 42, p. 223).

Nuevas especies de leguminosas sudamericanas [New species of South American legumes], A. BURKART (*Darwiniana*, 5 (1941), pp. 57-73, figs. 5).

Rasgos principales de fitogeografía argentina [Principal features of Argentine phytogeography], J. FRENGUELLI (*Rev. Mus. La Plata. n. ser.*, 3 (1941), *Bot.*, No. 13, pp. 65-181, pls. 58, figs. 3, map 1).—A monograph with six-page bibliography.

Comportamiento fenológico, de las plantas perennes cultivadas en la región de la Ciudad de Buenos Aires.—Observaciones del año 1940 [Phenological behavior of perennial plants cultivated in the vicinity of Buenos Aires.—Observations of 1940], A. L. DE FINA and E. C. CLOS (*Darwiniana*, 5 (1941), pp. 279-298, figs. 2; *Eng. abs.*, pp. 296-298).—About 450 species in not less than 104 families of perennials are said to be grown in this region, most of them introduced. Data on the dates of leaf fall, flowering, and fruit maturity are presented.

La vegetación de la provincia de Santa Fe (R. A.), A. E. RAGONESE (*Darwiniana*, 5 (1941), pp. 369-416, pls. 12, figs. 3).—This presents the results of

an ecological study of the Argentine Province of Santa Fe, with check list of species by plant families.

**Recursos naturales del reino vegetal en Bolivia** [Natural plant resources of Bolivia], M. CÁRDENAS (*Chron. Bot.*, 6 (1941), No. 17-18, pp. 404-406).—A brief summary.

**Aspecto general de la vegetación de Bolivia** [General aspects of Bolivian vegetation], M. CÁRDENAS (*Chron. Bot.*, 6 (1941), No. 19-20, pp. 452-454).

**Über zwei terpenführende Lauraceen Nordbrasilien** [Two terpene-yielding species of the Lauraceae in northern Brazil], P. VON LUETZBURG (*Angew. Bot.*, 22 (1940), No. 3, pp. 191-200, figs. 2).—On *Ocotea barcellensis* and *Aniba roseoedora*.

**The natural resources of Costa Rica**, A. F. SKUTCH (*Chron. Bot.*, 6 (1941), No. 17-18, pp. 399-402).—A brief summary, with special reference to agricultural crops, timber, and fiber and medicinal plants.

**The vegetation of Ecuador**, a brief review, H. K. SVENSON (*Chron. Bot.*, 6 (1941), No. 19-20, pp. 446-448, fig. 1).

**Plant resources of Guatemala**, W. POPENOE (*Chron. Bot.*, 7 (1942), No. 1, pp. 16-19).

**The vegetation of the Guianas**, a brief review, A. C. SMITH (*Chron. Bot.*, 6 (1941), No. 19-20, pp. 449-452, fig. 1).

**The vegetation of Honduras**, a brief review, T. G. YUNCKER (*Chron. Bot.*, 7 (1942), No. 1, pp. 26-27).

**The vegetation of the Lesser Antilles**, a brief review, W. H. HODGE. (Mass. State Col.). (*Chron. Bot.*, 6 (1941), No. 17-18, pp. 402-404, figs. 2).

**The phytogeography of Peru**, L. WILLIAMS (*Chron. Bot.*, 6 (1941), No. 17-18, pp. 406-410, fig. 1).—A brief conspectus of the vegetation of the coast, Sierra, and eastern slopes, with a summary of botanical explorations in Peru.

**La vegetación del Uruguay** [The vegetation of Uruguay], B. ROSENGUETT GURVICH (*Chron. Bot.*, 6 (1941), No. 17-18, pp. 410-411).—A brief summary of the ecological zones and their constituents.

**Recursos vegetales del Uruguay** [The plant resources of Uruguay], A. BOERGER (*Chron. Bot.*, 7 (1942), No. 1, pp. 27-29).

**Medical mycology in Latin America**, C. W. EMMONS (*Chron. Bot.*, 7 (1942), No. 1, pp. 15-16).—A review with partial bibliography.

**New or little known Ascomycetes collected in São Paulo in 1936**, A. E. JENKINS, H. P. KRUG, and E. K. CASH. (U. S. D. A. et al.). (*Mycologia*, 33 (1941), No. 4, pp. 390-404, figs. 3).

**Uredinales of New Guinea, IV**, G. B. CUMMINS. (Ind. Expt. Sta.). (*Mycologia*, 33 (1941), No. 4, pp. 380-389, figs. 14).—This installment (E. S. R., 85, p. 315) contains much new taxonomy among the genera of rust fungi.

**A study of root-nodule bacteria of certain leguminous plants**, S. S. POSADAS (*Philippine Agr.*, 30 (1941), No. 3, pp. 215-226, fig. 1).—Strains of *Rhizobium leguminosarum* from *Crotalaria juncea*, *C. usaramoensis*, *Pueraria javanica*, *Tephrosia candida*, and *T. noctiflora* were isolated, and their morphology, cultural characters, and physiology were studied and compared.

**Mutability of nodule bacteria**, N. A. KRASSILNIKOV (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S.*, n. ser., 31 (1941), No. 1, pp. 75-76).—After a prolonged culture in filtrates of *Rhizobium trifolii*, the nodule bacteria of vetch, pea, alfalfa, and bean acquired the ability to infect clover and to form nodules on its roots. Fermentative, but not cultural or morphological, changes were also significantly affected in this way.

**Liebig and the organic nutrition of plants**, H. R. KRAYBILL. (Ind. Expt. Sta.). (*Amer. Fert.*, 94 (1941), No. 8, pp. 5-7, 24, 26).—A fuller account of the historical paper previously noted (E. S. R., 84, p. 448).

**Simultaneous formation of a  $\beta$ -gentiobioside and a  $\beta$ -glucoside in gladiolus corms treated with chemicals**, L. P. MILLER (*Contrib. Boyce Thompson Inst.*, 12 (1941), No. 2, pp. 163-166).—"Condensation of ethylene chlorohydrin with *D*-glucose to form the  $\beta$ -glucoside and formation of the  $\beta$ -gentiobioside from absorbed *o*-chlorophenol took place in gladiolus corms even when the chemical treatments were carried out under conditions involving the simultaneous production of the two glycosides. No evidence was obtained for the formation of either  $\beta$ -2-chloroethyl-gentiobioside or  $\beta$ -*o*-chlorophenyl-*D*-glucoside."

**Fate of chloral hydrate absorbed by growing plants of *Lagenaria leucantha***, L. P. MILLER (*Contrib. Boyce Thompson Inst.*, 12 (1941), No. 2, pp. 167-169).—*L. leucantha* plants were shown to form  $\beta$ -2,2,2-trichloroethyl-*D*-glucoside when grown in a medium containing chloral hydrate.

**Atropine transference from stock (*Datura stramonium*) to scion (*Solanum lycopersicum*)**, S. J. KRAJEVOJ and I. NECHAEV (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 31 (1941), No. 1, pp. 69-71, figs. 2).—Atropine was found to pass from jimson weed stock to tomato scion.

**Succinic acid as a metabolite in plant tissues**, G. W. PUCHER and H. B. VICKERY. (Conn. [New Haven] Expt. Sta.). (*Plant Physiol.*, 16 (1941), No. 4, pp. 771-783, fig. 1).—"Succinic acid is shown to be present in a number of normal plant tissues, although the proportion found was in all cases considerably less than 1 percent of the dry weight. As compared with malic, oxalic, or citric acid, it is a minor acid constituent. A study was made of the behavior of succinic acid during the development of the tobacco plant. The extensive changes in amount and in concentration that this substance undergoes indicate that it may be regarded as one of the more active metabolites of the tissues. . . . The observations show that one more of the acids concerned in this scheme of reactions is widely distributed in plants, and that the changes in amount present, at different stages of growth of the tobacco plant, are such as to suggest that succinic acid is involved in the reactions that take place within the cells. This behavior is to be anticipated if some such cyclic series of chemical reactions does indeed lie at the basis of one of the fundamental physiological functions of plant cells."

**Transformation of sugars in excised barley shoots**, R. M. MCCREADY and W. Z. HASSID. (Univ. Calif.). (*Plant Physiol.*, 16 (1941), No. 3, pp. 599-610, figs. 2).—"Sucrose can be synthesized in barley plants when any one of glucose, fructose, mannose, galactose, maltose, or lactose is supplied. The plants thus apparently possess mechanisms to convert monosaccharides into glucose or fructose and to hydrolyze disaccharides into their monosaccharides, which are then used for sucrose synthesis. Sucrose synthesis from monosaccharides can take place in etiolated plants in darkness, showing the process to be independent of light and chlorophyll. Arabinose, xylose, mannitol, and sorbitol, and gluconic and pyruvic acids were not utilized by the plant for sucrose formation. After respiring for 24 hr. the sucrose in excised barley shoots gradually diminished, apparently due to hydrolysis, but the reducing sugars remained at about a constant level throughout that period. It was only after the sucrose was entirely depleted that a diminution in the reducing sugars could be detected. It was also shown that an excess of reducing sugars induces synthesis of sucrose, whereas an excess of sucrose favors the reverse process of hydrolysis. Sucrose synthesis did not occur without the presence of  $O_2$ , indicating this process to be aerobic. There are 14 references.

**Further growth experiments with fluorescent dyes**, J. SELLEI (*Growth*, 5 (1941), No. 1, pp. 27-52, figs. 11).—As previously shown,<sup>2</sup> plant growth can be

<sup>2</sup> *Growth*, 4 (1940), No. 2, pp. 145-156, figs. 6.

increased by various dyes. The effect of fluorescent dyes was found to depend mainly on the amounts and concentration. Highly diluted and applied under proper conditions of soil, weather, light, and planting and in proper concentrations, they stimulated plant growth, making roots, foliage, flowers, and crop sturdier and more abundant. In most cases, treated plants were also improved in quality. Highly diluted fluorescent dyes can also show favorable results when used together with other plant stimulants. Concentrated dyes inhibited growth without toxic effects, since the dwarfed plants bore flowers and fruit. Methods were worked out to determine the optimum dye concentration under different plant growth conditions.

Current approaches to the plant hormone problem, G. S. AVERY, JR. (*Collect. Net*, 16 (1941), No. 3, pp. 45, 47-50).

Ein neues Verfahren der Wuchsstoffstimulation [A new method of stimulation by growth substances], H. U. AMLONG and G. NAUNDORF (*Ber. Deut. Bot. Gesell.*, 59 (1941), No. 1, pp. 32-44, pl. 1, fig. 1).—When roots of *Vicia faba* were immersed for 3-24 hr. in 0.001 M solutions of K- $\alpha$ -naphthylacetate or K- $\beta$ -indolylacetate and then left for further growth in sawdust, they showed after 10 days a considerable increase in lateral roots over the untreated controls. For K- $\alpha$ -naphthylacetate a 6-hr. immersion proved to be optimum. By immersing the roots of young plants in growth substance solutions, increased yields were obtained in field tests with tobacco and six members of the cabbage family, and increases in the number of blooms on pansies reached as high as 65 percent. Of ascorbic acid and the two above substances tested, the first acted most positively, in every case giving an increased yield, whereas the other substances—and especially the K- $\alpha$ -naphthylacetate (probably due to the higher dosage)—occasionally caused inhibitions. The combination K- $\alpha$ -naphthylacetate+ascorbic acid was less active than either constituent alone. On the contrary, the mixture 1/2000 M ascorbic acid+1/2000 M K- $\beta$ -indolylacetate+1/5000 M vitamin B<sub>1</sub> far surpassed all other substances tested.

Estudios de fisiologia vegetal.—I, Accion de la insulina sobre la celula vegetal [Plant physiological studies.—I, The action of insulin on plant cells], F. VILLAGRAN PRADO (*An. Inst. Biol. [Univ. Nac. Mex.]*, 12 (1941), No. 1, pp. 43-48; *Eng. abs.*, p. 48).—Insulin solutions are reported to have caused marked activation of the germination process in seeds of bean and wheat, an increase in the development of the bacteria and yeasts from "aguamiel" (from which pulque is made), and to have been responsible for the absence of flowers on otherwise normal bean plants from treated seeds.

Chemical stimulation of ovule development and its possible relation to parthenogenesis, J. VAN OVERBEEK, M. E. CONKLIN, and A. F. BLAKESLEE (*Amer. Jour. Bot.*, 28 (1941), No. 8, pp. 647-656, figs. 7).—"A 0.1-percent solution or emulsion of the ammonium salt of naphthaleneacetic acid injected into the young ovaries of 4n *Melandrium* induces parthenocarpic fruits with well-enlarged placentae and ovules of increased size which develop seed coats and nucellus, but no embryo. Applied to the outside of the ovary or peduncle, the emulsion induces ovary but not ovule development. Naphthaleneacetic acid or indolebutyric acid injected into the ovaries of *Datura stramonium* induces parthenocarpic fruits with greatly enlarged ovules which develop seed coats and often contain a pseudoembryo consisting of several hundred cells. The pseudoembryo originates by proliferation from the inner layer of the integument (endothelium) surrounding the embryo sac. Attempts have so far failed to stimulate division of the egg cell or to increase ovule growth beyond the stage induced by auxin through additional injections of many physiologically active substances. A working hypothesis of the mechanism of the development of fruit, seed, and embryo

is proposed which involves (1) stimulation of development of ovaries, placentae, and ovules, and (2) stimulation of division of polar nucleus and egg cell with or without previous fertilization."

**Some chemical differences between artificially produced parthenocarpic fruits and normal seeded fruits of tomato, B. E. JANES** (*Amer. Jour. Bot.*, 28 (1941), No. 8, pp. 639-646, figs. 2).—The fruits studied were produced by indolebutyric and indoleacetic acids and by use of pollen of *Lycopersicon peruvianum*, size of fruit varying with production method. The titratable acidity in both parthenocarpic and seeded fruits was the same during all stages of development except for a short time during ripening, when the acid in the seeded fruits was somewhat higher. There were, however, marked differences in the distribution of the acid in different parts of the two kinds of fruit. The percentage of starch in the parthenocarpic fruit was greater at all developmental stages except for ripeness, when both kinds of fruit were very low in starch. Early in development the percentage of sugar was nearly the same in all parts of the fruit. As they matured it increased in the parthenocarpic faster than in the seeded ones, and in the red ripe fruit each region of the parthenocarpic had more sugar than corresponding regions of the seeded fruit. The differences in starch and sugar were reflected in the dry weight and soluble solids. The method used in stimulating parthenocarpic fruit had little or no influence on the chemical variations between them and the seeded fruit. From the fact that the differences observed were almost entirely in the locules, it seems evident that the developing seed profoundly influences the chemical composition of the fruit.

**Conditions affecting the acceleration of protoplasmic streaming by auxin, B. M. SWEENEY** (*Amer. Jour. Bot.*, 28 (1941), No. 8, pp. 700-702, figs. 3).—The experimental conditions resulting in acceleration as noted by Thimann and the author (*E. S. R.*, 78, p. 760) were compared with those failing to do so, as noted by Olson and Du Buy (*E. S. R.*, 84, p. 162). In oat coleoptile sections infiltrated with water or with 1 percent fructose no acceleration could be noted with any concentration of indole-3-acetic acid, but if not infiltrated or if infiltrated with air the rate of streaming was increased by auxin at 0.01-1 mg./l., as previously reported. Air-infiltrated sections showed more marked acceleration than unfiltered sections. Use by Olson and Du Buy of infiltrated sections may have been the principal factor accounting for their failure to observe accelerations of protoplasmic streaming with auxin.

**Über die Verhinderung des Etiollements [Prevention of etiolation], E. BÜNNING** (*Ber. Deut. Bot. Gesell.*, 59 (1941), No. 1, pp. 2-9).—In young auxin-treated *Sinapis alba* seedlings, the short as well as the long wavelengths of light are able to inhibit etiolation. A photoinactivation by auxin is the decisive factor here, apparently being brought about by absorption of radiation in the carotenoids and especially in the chlorophyll. Later it is only the short wavelengths which are active, apparently through the release of stimulatory processes leading to an arrest of growth in length. This kind of formative action is induced by absorption of radiation in the carotenoids.

**Factors affecting root formation of Phaseolus vulgaris, K. V. THIMANN and E. F. POUTASSE** (*Plant Physiol.*, 16 (1941), No. 3, pp. 585-598, figs. 3).—Studying the rooting of isolated leaves, the survival of such cuttings was greatly improved by the presence of a portion of the stem and varied roughly with the amount attached. The material was extremely sensitive to auxin, over 0.025 mg. indoleacetic acid causing injury, but auxin treatment in nearly all tests considerably increased the number of roots formed. Rooting was slightly depressed by a complete nutrient solution or by the Ca or Mg salts composing it,

was strongly promoted by  $\text{KNO}_3$ , and even high dilutions of  $(\text{NH}_4)_2\text{SO}_4$  were inhibitory. The growth and maintenance of roots already formed was improved by the complete solution. Of the organic N sources studied, adenine proved most effective, greatly increasing both the percentage of cuttings which rooted and the number of roots formed. Asparagine, guanine, choline, and uracil were also effective to a lesser extent in about that order, and yeast nucleic acid and nicotinic acid showed slight but variable effects. It is concluded that the N nutrition of the isolated leaf is highly important in determining both its survival and its root formation.

**Formation of auxin in yeast cultures**, T. W. ROBINSON and T. J. B. SMITH (Univ. Ill. et al.). (*Jour. Gen. Physiol.*, 24 (1941), No. 6, pp. 765-769, figs. 2).—Auxin production by bakers' yeast cells was found to resemble the formation observed in other organisms, such as *Rhizopus* and *Rhizobium*, which also form auxins in their culture media. The yield increased with sucrose concentration, and decreased with peptone concentration and with increase in rate of cell multiplication. Below pH 5 the total yield was directly proportional to the H-ion concentration. Thus it was proposed that certain growth conditions favor the breakage of the link between auxin and its protein carrier and consequently accelerate the rate of excretion of auxin into the growth medium.

**Production of solutes in growing epidermal cells**, W. A. BECK (*Plant Physiol.*, 16 (1941), No. 3, pp. 637-642, fig. 1).—A method was devised and is here described for determining the amount of solute produced in growing cells. When the enlargement of growing epidermal cells and the amount of solute produced therein are determined and correlated for etiolated sunflower seedlings, it is found that the amount of solute produced is proportional to the growth of the cells. It is concluded that the production of solute facilitates the growth process in general and the growth of the wall by intussusception in particular, but that it cannot legitimately be regarded as the prime cause of growth by cell enlargement. There are 14 references.

**Selective absorption of cations by higher plants**, R. COLLANDER (*Plant Physiol.*, 16 (1941), No. 4, pp. 691-720, figs. 3).—Some 20 phanerogamous plants differing in ecological type were cultured for about 2 mo. in complete nutrient solutions containing several cations in equivalent amounts, when their cation composition was determined by spectral analysis. The cations most closely studied were Na, K, Rb, Mg, Ca, Sr, and Mn. The differences among the plant species cultured in a given solution proved very unequal with regard to the different cations, but the cause of these variations is unknown. The differences observed were for the most part truly specific in character, single species being constantly found relatively rich in certain cations and other species just as constantly so for other cations. With one exception, all halophytes were very rich in Na; three species (buckwheat, corn, and sunflower) were distinguished by their unusually large exclusion of Na; all chenopodiaceous plants (as well as buckwheat) were remarkably rich in Mg; Ca and Sr were absorbed in greatest amounts by sunflower, buckwheat, and white mustard; and oats, corn, and spinach absorbed the last two cations in least amounts. All plants absorbed Rb and Cs almost as rapidly as K, and Sr almost as readily as Ca. On the other hand, all the other cations studied exhibited no mutual correlation in absorption rates. The specific differences among the absorption characteristics of different species were so great that it is impossible to arrange the absorption of cations in any certain order that would be valid for all plants investigated, but the following data are valid for the majority: K, Rb, and Cs are, in general, the cations most copiously accumulated. The next place is in most cases occupied either by Ca and Sr or, about as frequently, by Mg, Li, Na, and Mn. K and Rb ions

and Ca and Sr ions depress the absorption of each other more than do any other cations studied in this respect. It is also notable that Rb or Sr, in the presence of excess K or Ca, respectively, do not obey the general rule that the absorption ratio of a given ion increases when its concentration in the medium decreases. On the contrary, the absorption ratios of Rb and Sr remain constant if only the total concentration of K+Rb, respective to Ca+Sr, is held constant. These findings are explained by assuming that the ions K and Rb, and Ca and Sr, behave in the salt absorption of plants somewhat as identical ions or as two isotopes of the same element. The very complex nature of the selective salt absorption of higher plants is stressed.

**The effect on barley seedlings of some interrelations of cations and anions in a three-salt nutrient solution, W. R. MULLISON.** (Purdue Univ.). (*Plant Physiol.*, 16 (1941), No. 4, pp. 813-820, figs. 2).—Plants of the nutrient triangle in which the anions were varied were as a whole better than where the cations were varied. Variations in the nutrient solutions had their greatest effect on growth of the plant tops, root growth being much more uniform except in the absence of K, where a marked decrease in their size and weight followed. With nitrates absent, or when a high phosphate-low nitrate relationship existed, a marked P toxicity became apparent. K deficiency symptoms appeared extremely early, before signs of deficiency or toxicity of any other element, and a severe dieback of the seedling leaves resulted. A high Mg concentration in conjunction with an absence of Ca resulted in the death of the terminal meristem and caused some stunting and chlorosis.

**Use of nitric acid in control of pH and nitrate levels in nutrient solution, F. M. EATON.** (U. S. D. A.). (*Plant Physiol.*, 16 (1941), No. 4, pp. 834-836).—The author calls attention to the advantage of using HNO<sub>3</sub> for maintaining at one and the same time both H-ion concentrations and nitrate levels.

**Die bedeutung der Chloridernährung für die Pflanze, insbesondere für Gemüse [The significance of chloride nutrition for plants, especially vegetables], W. SCHUPHAN** (*Forschungsdienst*, 11 (1941), No. 2, pp. 161-176).—A review, with 107 references.

**On the occurrence of selenium in plants, H. G. BYERS.** (U. S. D. A.). (*Chron. Bot.*, 7 (1942), No. 1, pp. 4-6).

**Water uptake and root growth as influenced by inequalities in the concentration of the substrate, F. M. EATON.** (U. S. D. A.). (*Plant Physiol.*, 16 (1941), No. 3, pp. 545-564, figs. 5).—When corn and tomato plants were grown with their roots divided between two or more solutions of unequal concentration they developed more roots and took up more water in the dilute solution, and correlative findings indicated that osmotic pressures rather than specific ion effects were primarily involved. Roots divided between distilled water and concentrated nutrient made more growth in the latter, but almost twice as much water was withdrawn from the distilled water during the first 3 days of the test, though this was later reversed. "The investigations were undertaken as a means of appraising the effects of the variability in the concentration of the soil solution often found within the root zone of plants growing on irrigated lands. When soils are permeable and extensively leached this variability may be slight, but under other circumstances it may be great. An example is presented of the situation found in a permeable but lightly irrigated orchard soil wherein 15- to 60-fold variations in the concentrations of sulfate and chloride, respectively, were found within the root zone of single trees." There are 18 references.

**Bound water in plant sap and some effects of temperature and nutrition thereon, R. C. CHANDLER.** (Univ. Calif.). (*Plant Physiol.*, 16 (1941), No. 4,

pp. 785-798, figs. 4).—Using sap expressed from hardened and unhardened plants of a hardy wheat variety, the cryoscopic method, and two types of reference substances, and interpreting the behavior of the biological solution on the basis of a similar study on artificial colloidal and noncolloidal solutions, it appeared that "bound" water in plant sap is a reflection of all the components of the sap and of the reference substance where such is used. It is a hypothetical amount of water estimated to account for the difference in value of a property of water in complex solution and its value in simple solution. Water in sap seems to have the normal properties of water in any complex solution. Changes in the thermodynamic activity of water in sap as plants harden may be accounted for most satisfactorily by the quantitative and qualitative changes in solutes as a result of physiological response to environment.

**Variation and correlation of stomatal frequency and transpiration rate in *Phaseolus vulgaris*, H. B. SMITH** (*Amer. Jour. Bot.*, 28 (1941), No. 8, pp. 722-725, fig. 1).—In the bean leaf blades stomatal frequency was highest near the apex and lowest near the midrib, and in different leaves it was apparently higher at the upper than at the lower levels of a plant. Variations were much greater between leaves at different levels than between the parts of a single leaf blade, but the leaves at different levels did not differ in transpiration rate any more than did the parts of a single blade. For comparing plants as to transpiration rate, any comparably exposed and full-grown leaflet of the young plants was used. For comparing them in stomatal frequency, the lower right portion of the plumular leaf was the representative sample used. A positive correlation of  $0.431 \pm 0.062$  between stomatal frequency and transpiration rate was found.

**Respiration of leguminous root nodules, G. F. ASPREY and G. BOND** (*Nature* [London], 147 (1941), No. 3735, p. 675).

**A highly simplified thermionic control of temperature, R. H. WALLACE and R. J. BUSHNELL** (Univ. Conn.). (*Plant Physiol.*, 16 (1941), No. 3, pp. 647-650, figs. 2).—The scheme described and illustrated is a further adaptation of thyratron methods.

**Synthetic ability of plants as affected by vernalization, I. N. KONOVALOV and T. M. POPOVA** (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., ser.*, 31 (1941), No. 1, pp. 58-60, figs. 3).—From studies of the accumulation of organic matter, formation of protein per unit time in leaves, and the enzyme activity of the plants, it is considered probable that the acceleration of leaf growth and changes in enzyme activity furnish the main basis for the increased productivity following vernalization.

**Flowering in *Digitalis purpurea* initiated by low temperature and light, J. M. ARTHUR and E. K. HAVILL** (*Contrib. Boyce Thompson Inst.*, 12 (1941), No. 2, pp. 111-117, fig. 1).—*D. purpurea* plants given a cold treatment of about 4 mo. (June-October) at 41° F. flowered rapidly when returned to a long day and higher temperature in a greenhouse. The best method found for preserving a slow growth and an excellent appearance of the plants during the long storage treatment was to remove them to a slatted shade in sunlight for 2 days and nights each week. Plants left out-of-doors in cold frames until December 18, then returned to a long day and higher temperature in the greenhouse, flowered after 2½ mo., whereas about 1 mo. of lighting was required after the more carefully regulated cold room treatment at 41°. It is proposed that this flowering response in plants brought about by low temperature be called "thermoperiodism."

**The effects of heat and ultraviolet light on certain physiological properties of yeast, T. F. ANDERSON and B. M. DUGGAR** (Univ. Wis.). (*Amer. Phil. Soc. Proc.*, 84 (1941), No. 5, pp. 661-688, figs. 6).—Wavelengths shorter than 2,200 a. u. reduced immediately the rate of respiration and caused the cells to

stain with methylene blue. Irradiation with  $\lambda 2,650$  caused little reduction in respiratory rate, but prevented the normal increase of respiration in the nutrient. Exposure to  $50^{\circ}$  C. rapidly reduced the respiratory rate, but brought only a gradually increasing tendency of the cells to stain with methylene blue. All these treatments rapidly reduced the colony-forming ability of the cells. When heat and radiation were combined, the latter sensitized both the colony-forming ability and the staining resistance to subsequent heat treatment. On the other hand, the respiratory rate was independent of the order of heat and radiation treatments. These and further results are consistent with the view that wavelengths shorter than 2,200 a. u. and heat act directly on the respiratory and stain-resisting mechanisms. In preventing the normal increase in respiration,  $\lambda 2,650$  inactivates nucleoproteins responsible for producing one or more links in the enzyme chain. That irradiation with  $\lambda 2,650$  sensitizes the cells to killing by heat suggests that some nucleoproteins may be injured by irradiation without destroying patterns for forming additional cellular constituents. However, patterns so weakened are readily destroyed by heat. There are 35 references.

**An inexpensive integrating light recorder**, V. G. SPRAGUE and E. M. WILLIAMS. (U. S. D. A. coop. Pa. State Col.). (*Plant Physiol.*, 16 (1941), No. 3, pp. 629-635, figs. 3).—Though it may not be possible to control the incident light available to experimental plants at various times, interpretations of the results obtained might be facilitated if the total amount of light which the plant had received were known. To overcome the difficulties encountered with recording instruments previously used and to reduce the cost of equipment, an integrating light recorder was constructed from a few electrical parts obtainable from a radio dealer. It is described, and its applications and advantages are discussed.

**Treating seed with light**: Experiments in Denmark provide some very interesting conclusions on the possible viability of seed, C. JENSEN (*Seed World*, 49 (1941), No. 9, pp. 20-21, fig. 1).—A preliminary report.

**Photoperiodism**, R. H. ROBERTS. (Univ. Wis.). (*Chron. Bot.*, 6 (1941), No. 19-20, pp. 437-438).—A brief review of recent trends in studies of photoperiodism, and suggestions as to lines for future investigation.

**The effect of high concentrations of carbon dioxide on the glutamine and asparagine metabolism of the sugar beet**, J. M. FIFE and W. C. FERGUSON. (U. S. D. A.). (*Plant Physiol.*, 16 (1941), No. 4, pp. 677-690, fig. 1).—Asparagine-amide N and  $\text{NH}_3$  increased in beet leaf extracts when heated to  $80^{\circ}$  C., filtered, and allowed to stand, while the glutamine-amide N decreased. No significant change in the N fractions occurred when the aliquots were allowed to stand for 48 hr., provided the H-ion concentration was increased from pH 5.9 to 4.5. A large increase in  $\text{NH}_3$  resulted when the beet leaf blades were exposed to 20 and 40 percent  $\text{CO}_2$ . This increase in  $\text{NH}_3$  could be accounted for by the decrease in asparagine-amide and glutamine-amide N. When exposed to 80 and 100 percent  $\text{CO}_2$  there was a significant increase in soluble N, a large increase in  $\text{NH}_3$  and asparagine-amide N, and a decrease in glutamine-amide N. When whole leaves were treated with 20 percent  $\text{CO}_2$  and the petioles only were analyzed, there was an increase in  $\text{NH}_3$  and asparagine-amide N and a decrease in glutamine-N. The asparagine-amide N appeared to be distributed nearly evenly between the petioles and blades, whereas the glutamine-amide N was concentrated in the petioles. The degree of N fertilization of beets apparently has an important bearing on their glutamine and asparagine metabolism while under the influence of high  $\text{CO}_2$  concentrations. The leaves of heavily fertilized plants responded to a 20-percent  $\text{CO}_2$  treatment by a decrease in glutamine-amide N, whereas leaves of unfertilized plants responded with an increase in glutamine-amide N. Complex soluble substances (probably peptides) were hydrolyzed in the

plant while under the influence of high CO<sub>2</sub> concentrations, yielding asparagine-amide N and under certain conditions glutamine-amide N.

**Automatic conductivity measurements of CO<sub>2</sub>,** D. G. CLARK, J. SHAFFER, JR., and O. F. CURTIS. (Cornell Univ.). (*Plant Physiol.*, 16 (1941), No. 3, pp. 643-646, figs. 2).—A conductivity system for measuring photosynthesis, by which readings are automatically recorded as frequently as desired, is described. The apparatus should be easily adjustable to give a wide choice of frequencies of readings ranging from 1-2 min. up to 1 hr. or more and should be adaptable to many different experiments.

**Device for measuring the rate of photosynthesis in plants,** A. A. NICHIFOROVICH and N. G. VASSILIEVA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 31 (1941), No. 1, pp. 65-68, figs. 2).

**Photosynthesis with radioactive carbon, and the distribution of the intermediate products in the plant cell,** A. W. FRENKEL (Univ. Calif.). (*Plant Physiol.*, 16 (1941), No. 3, pp. 654-655).—A note on experiments concerning the distribution of the initial photosynthetic products within *Nitella* cells, radioactive C being used as a tracer.

**Photosynthesis in plants at high altitudes,** O. V. ZALENSKY (*Comp. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 31 (1941), No. 1, pp. 61-64, fig. 1).—From the data obtained it is assumed that under the prevailing conditions in the eastern Pamirs at heights of about 6,000 m. CO<sub>2</sub> assimilation by the higher plants is impossible even during the warmest season, except for a few days and then only within a very short time. This makes the continued existence of these plants impossible at such altitudes even in a congenial edaphic environment.

**Some aspects of the phyllotaxy of tobacco,** H. A. ALLARD. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 1, pp. 49-55, fig. 1).—Studying a number of commercial American varieties of tobacco, *Nicotiana rustica*, *N. gossei*, and *N. glauca*, several normal leaf arrangements were found expressed by the fractions 1/3, 2/5, 3/8 and 5/13. The 3/8 and 5/13 phyllotaxies are the usual arrangements in tobacco, the 1/3 arrangement being found only in suckers where the main stem is 2/5. Disturbance of normal growth by cutting or topping usually resulted in a lower order of phyllotaxy than that of the main stem. Spiral arrangement may be clockwise or counterclockwise and seems to be a much more stable individual character than the fractional phyllotaxy. It probably never reverses itself except from abnormal torsions.

**The variations in form of mycorrhizal short-roots of *Pinus virginiana* Mill. associated with certain soil series,** A. P. KILLEY (*Landenberg, Pa.: Landenberg Lab.*, 1941, pp. 10).

**Histogenesis in the roots of *Holcus sorghum* L.,** H.-H. CHI (*Iowa State Col. Jour. Sci.*, 16 (1942), No. 2, pp. 189-205, pls. 4).—A study of the germination and root development of sorghum is presented.

**A sieve tube translocation model,** R. E. GIBTON. (Purdue Univ.). (*Plant Physiol.*, 16 (1941), No. 4, pp. 831-833, fig. 1).—A simple demonstration model is described and illustrated.

**The comparative anatomy of the secondary xylem of five American species of *Celtis*,** M. J. COX. (Univ. Ill.). (*Amer. Midland Nat.*, 25 (1941), No. 2, pp. 348-357, figs. 6).

**Systematic anatomy of woods of the "Burseraceae,"** I. E. WEBBER (*Lilloa*, 6 (1941), No. 2, pp. 441-466, pls. 4; *Span. abs.*, p. 441).—The wood anatomy is presented of this group comprising 15-16 genera and about 50 species of tropical woody plants, most of which are large trees, and comparisons are made with 4 other families believed to be of common extraction because of similarities in structure.

Recent work on the types of embryo-sacs in angiosperms—a critical review, P. MAHESHWARI (*Jour. Indian Bot. Soc.*, 20 (1941), No. 5-6, pp. 229-261, figs. 3).—A review with nine pages of references.

The embryogeny and seedling morphology of "*Juglans regia*" L., C. G. NAST (*Lilloa*, 6 (1941), No. 1, pp. 163-205, pls. 17, figs. 6; *Span. abs.*, p. 163).

Embryoless dill seeds, F. FLEMION and E. WATERBURY (*Contrib. Boyce Thompson Inst.*, 12 (1941), No. 2, pp. 157-161, fig. 1).—In 12 lots of dill seeds, most of those failing to germinate proved to be without embryos though the endosperm was present. The occurrence of these embryoless seeds is frequent and accounts for the great variation in the germinative capacity found in the different lots.

Nouvelles observations cytologiques sur le manioc cultivé [New cytologic observations on cultivated manihot], P. BOITEAU (*Chron. Bot.*, 6 (1941), No. 17-18, p. 388).

A technique for the electron microscopic examination of encapsulated bacteria, E. A. KREGEL, J. W. APPLING, B. F. SHEMA, and G. R. SEARS (*Science*, 94 (1941), No. 2451, p. 592).

Studies on the myxobacteria, J. M. BEEBE. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 15 (1941), No. 3, pp. 307-337, pls. 4, figs. 6).—An improved method of isolating myxobacteria from soils and dungs, and *Chondroccoccus blasticus* n. sp., are described. The distribution of species of this group in Iowa soils around Ames is shown to be fairly general as regards the families Myxococcaceae and Polyangiaceae. Species of *Myxococcus* were by far the most common, though other genera were represented. Members of the families Sorangiaceae or Archangiaceae were not observed. The biotic relationship of the myxobacteria with the true bacteria is discussed, and it is suggested that it is one of parasitism rather than strict symbiosis or association. Cells of the true bacteria are necessary for the best growth and normal fruiting of some of the myxobacteria, the host cells being destroyed by an extracellular lytic enzyme. Myxobacterial growth rates and fruiting body production increased proportionately with the concentrations of killed bacterial cells up to about 50 mg. per 100 cc. of medium, being less marked above that point. A possible preference for gram-negative, nonsporiferous, nonchromogenic bacteria is noted.

Notes on the CO<sub>2</sub>-requirement of bacteria, O. RAHN. (Cornell Univ.). (*Growth*, 5 (1941), No. 1, pp. 113-118).—"Bacteria need carbon dioxide not only during the lag phase for purposes of rejuvenation but also during the period of active growth. Their metabolism at this stage of development is so great that the need of CO<sub>2</sub> can be proved only when very few cells are inoculated. With those bacterial species which produce CO<sub>2</sub> as a metabolic product, the need of CO<sub>2</sub> does not become evident if large numbers of cells are tested. In this case growth and multiplication are greatly retarded but not completely prevented. Species which do not produce CO<sub>2</sub> in their metabolism react more promptly to the removal of CO<sub>2</sub>. Even large inocula and young cells cannot overcome the absence of CO<sub>2</sub>."

Note on the utilization of carbon dioxide by heterotrophic bacteria, H. D. SLADE, H. G. WOOD, A. O. NIER, A. HEMINGWAY, and C. H. WERKMAN. (Iowa Expt. Sta. coop. Univ. Minn.). (*Iowa State Col. Jour. Sci.*, 15 (1941), No. 3, pp. 339-341).—*Staphylococcus candidus*, *Acrobacter aerogenes*, *Streptococcus paracitrovorus*, and two species of *Clostridium* were used in this study.

Cellulose decomposition by the saprophytic chytrids, A. J. WHIFFEN. (Univ. N. C.). (*Jour. Elisha Mitchell Sci. Soc.*, 57 (1941), No. 2, pp. 321-330, pl. 1, fig. 1).—By an isolation technic described and with a medium containing

mineral salts,  $\text{NH}_4\text{NO}_3$ , and cellulose, the cellulose-decomposing ability was demonstrated for seven species of fungi of the Chytridiaceae.

**Association between nitrogen-fixing and cellulose-decomposing micro-organisms**, H. L. JENSEN and R. J. SWABY (*Nature [London]*, 147 (1941), No. 3718, pp. 147-148).—From experiments briefly reported it appears that N fixation on the basis of cellulose requires either a recurrent exclusion of  $\text{O}_2$  or the cooperation of at least one anaerobic component in the microbial association. Therefore, the most favorable conditions for N gains by cooperation between N-fixing and cellulose-decomposing bacteria would seem to exist in heaps of decomposing plant material and in soils frequently subject to waterlogging rather than in well-aerated agricultural soils.

**The effect of bacterial contaminations upon the subsequent growth of fungi in the same medium**, C. L. PORTER. (Purdue Univ.). (*Ind. Acad. Sci. Proc.*, 49 (1939), pp. 75-76).—A bacterium closely related to *Bacillus subtilis* was found capable of producing products in potato dextrose agar sharply inhibitory to *Fusarium moniliforme* and *Diplodia zeae* and stable at 250° F. for 30 min. Since media contaminated by certain bacteria were found incapable of supporting normal development of some fungi, it is deemed unsafe to use sterile media previously contaminated by bacteria in any critical studies. Fungus-bacterial combinations are abnormal in probably every instance.

## GENETICS

**Regional differentiation in plant species**, J. CLAUSEN, D. D. KECK, and W. M. HIESEY (*Amer. Nat.*, 75 (1941), No. 758, pp. 231-250, figs. 7).—A discussion of the general relations between plant and climate, a closer study of climatic or regional races of *Potentilla glandulosa* and *Achillea millefolium*, and a summary survey of various other plant species led to the conclusion that the genetic-physiologic differentiation of a plant group is correlated with the climatic zones it occupies. This follows from the fact that the same kinds of environments are occupied by races having similar patterns of reaction, even though belonging to unrelated genera or families. It also appears that it is the genes rather than the chromosome number which determine the climatic adaptation. From the standpoint of environal fitness it is evident that the ecologically important unit is not the species but the regional climatic race (ecotype). The evolutionary and ecological ramifications of the survey are discussed in detail. Though there is no evidence that environment directly produces fundamental hereditary species changes, major environal alterations do "provide new habitats and refuges for the products of nature's continual experimentation among all the plant species that populate a given area."

**Production artificielle de mutations par irradiations**, Y. JEAN (*Bonne Terre*, 22 (1941), No. 7-12, pp. 171-186, figs. 4).

**Hybrid vigor and weight of germs in the seeds of maize**, J. H. KEMPTON and J. W. McLANE. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 2, pp. 65-80, fig. 1).—Studies of hybrid and selfed seed, endosperms, and embryos of corn confirmed results reported by Sprague (*U. S. R.*, 77, p. 82). Hybrid vigor in corn is often, although not invariably, reflected in the dry weight of resting embryos. Seed groupings based on texture and color of endosperm but with uniform genic backgrounds disclosed differences in germ weights. The increased weight of embryo relative to increased weight of endosperm offered equivocal evidence on the hypothesis that hybrid vigor results from the interaction of dominant factors favorable for growth.

**Intergeneric hybridization of cereals and other grasses, D. C. SMITH.** (U. S. D. A. coop. Wash. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 64 (1942), No. 1, pp. 33-47, pls. 2).—Attempts were made to hybridize wheat (*Triticum aestivum*) with grasses, including 15 species of *Agropyron*, 7 of *Elymus*, 2 of *Festuca*, *Lolium perenne*, and *Secale montanum* as pollen parents. Hybrid plants were obtained only in *T. aestivum* × *A. elongatum*, *T. aestivum* × *A. intermedium*, and *T. aestivum* × *A. trichophorum*. When varieties of rye (*S. cereale*) were studied in combinations with 9 species of *Agropyron*, 7 of *Elymus*, and *Bromus inermis*, *Hordeum bulbosum*, and *S. montanum*, the following were successful: *S. cereale* × *A. repens*, *S. cereale* × *A. sibiricum*, *S. cereale* × *A. trichophorum*, and *S. cereale* × *S. montanum*. Five species of *Agropyron*, 2 of *Bromus*, 9 of *Elymus*, and 4 of *Hordeum*, and *F. idahoensis* and *S. montanum* were used as male parents in crosses with *H. vulgare*, but no hybrids were obtained. Limited efforts to hybridize cultivated oats (*Avena sativa* and *A. byzantina*) with other grasses, particularly *Arrhenatherum elatius*, were unsuccessful. Hybrid plants studied were sterile in all crosses except those derived from *S. cereale* × *S. montanum*. Within wheat or rye, female parental varieties were not equal in compatibility as shown by hybrid seed development.

**Hybridization, cytology, and polyploidy of Gossypium, J. O. BEASLEY.** (Tex. Expt. Sta.). (*Chron. Bot.*, 6 (1941), No. 17-18, pp. 394-395).

**Inheritance of smooth and pitted bolls in Pima cotton, E. G. SMITH.** (U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 64 (1942), No. 2, pp. 101-103, fig. 1).—Pitted ( $B^p$ ) and smooth ( $B^s$ ) bolls in Pima cotton (*Gossypium barbadense*) behaved as allelic characters. The inheritance, as indicated by segregation in  $F_2$  and backcross populations, was monohybrid without indication of dominance. Success in analyzing the inheritance of smooth and pitted boll surface might be attributed to similar genetic backgrounds in the two strains used, i. e. P Hope and ordinary Pima.

**Inheritance of cluster habit and its linkage relation with anthocyanin pigmentation in upland cotton, J. W. NEELY.** (U. S. D. A. coop. Miss. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 64 (1942), No. 2, pp. 105-117, fig. 1).—In crosses between cotton strains characterized respectively by red plant, noncluster habit ( $R_1^{ro} R_1^{ro} Cl Cl$ ) and green plant, cluster habit ( $r_1^{ro} r_1^{ro} cl cl$ ), the  $F_1$  differed slightly from the noncluster parent, but the noncluster characteristic was dominant, or practically so. In  $F_2$  and backcross generations the ratios of noncluster to cluster obtained verified the previous conclusion that the characteristic is controlled by one genetic-factor pair. The  $R_1^{ro}$  and  $Cl$  genes were found to belong to the same linkage group, and the percentage of recombinations was not far from 18.5.

**Experimentally produced haploids in Nicotiana tabacum by means of X-rays, N. P. BADENHUIZEN** (*Natuurw. Tijdschr. Nederland. Indië*, 101 (1941), No. 8, pp. 240-242, figs. 4).

**A colchicine-induced tetraploid cabbage, E. H. NEWCOMER.** (Univ. N. C.). (*Amer. Nat.*, 75 (1941), No. 761, p. 620).—A brief account is presented upon the origination of a tetraploid self-fertile cabbage by the treatment of Ferry Hollander seedlings with a 0.2-percent solution of colchicine. The flowers and the pollen grains of the tetraploid were larger than those of normal diploid plants. One of the treated plants was a mixoploid with chromosome numbers of  $2n$  and  $4n$  in the same inflorescence.

**Cytological studies in Lactuca, T. W. WHITAKER and R. C. THOMPSON.** (U. S. D. A.). (*Bul. Torrey Bot. Club*, 68 (1941), No. 6, pp. 383-394, figs. 9).—Observations on the principal details of meiosis in nine  $F_1$  hybrids produced from a series of interspecific crosses in *Lactuca* are presented. Three of the crosses

were between species with 9 pairs, four between species with 9 and 17 pairs, and two between species with 17 pairs of chromosomes. An analysis of pairing behavior and irregularities indicated that the 9-chromosome species consist of at least two distinct compatibility groups. The 17-chromosome group was found very homogeneous and probably was descended from a single amphidiploid or may have resulted from a single occurrence of amphidiploidy. A closely related paper was recently noted (E. S. R., 86, p. 176).

**Inheritance of a leaf variegation in beans,** W. J. ZAUMEYER. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 2, pp. 119-127, fig. 1).—A type of variegation that appears both on the primary and trifoliate leaves of certain varieties of beans is described and discussed as to inheritance when affected varieties are crossed with varieties of normal green color. That the variegation is not a virus manifestation was indicated by a failure to infect susceptible varieties by the usual methods. The occurrence of a high percentage of lethals among the variegated plants in the progeny of crosses between susceptible and normal varieties is believed to indicate that such were true-breeding recessives. The survivors were probably carrying some of the inhibiting factors, possibly in the heterozygous condition. This type of heritable variegation has been found of importance in Wisconsin Refugee and, to a lesser extent, in Idaho Refugee, both of which had Corbett Refugee as one parent. For the most part the data on heritability supported the two-factor Mendelian hypothesis. The  $F_1$  plants of reciprocal crosses were normal green, and a ratio of 15 green plants to 1 variegated was observed in the  $F_2$  generation. The fact that the variegated recessive progenies, except in a few cases, did not breed true in the  $F_3$  generation is thought due to the presence of one or more inhibiting factors that suppressed the variegation factor.

**Inheritance of factors influencing sucrose percentage in *Beta vulgaris*,** J. O. CULBERTSON. (U. S. D. A. coop. Minn. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 3, pp. 153-172).—The inheritance of sucrose factors was studied in crosses between inbred lines of beets differing in percentage of sucrose. The average sucrose percentage of  $F_1$  and  $F_2$  approximated the mean of the parents.  $F_3$  progenies and progenies of selfed backcrosses were obtained that did not vary more than the parental inbreds and were as high in mean sucrose percentage as the high-sucrose parent. It appeared that relatively homozygous lines of desirable sucrose percentage could be obtained with comparative ease. Ability to store sucrose was inherited in a quantitative manner and depended upon the interaction of several factors. The correlation between the sucrose percentage of mother beets selected from segregating populations and the means of their inbred progenies was highly significant.

**Simple and complex periclinal tetraploidy in peaches induced by colchicine,** H. DERMEN. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), p. 141).—Tetraploid tissues were observed in peach seedlings following treatment of the newly germinated seed with colchicine. Enlarged pollen grains suggested that the tissues from which they developed were polyploid. An examination of sections of tips of growing stems showed in one case that the epidermis was tetraploid and the inner tissues diploid. In another plant, on one side the epidermis and all the cortex, except a small area next to the stele and pith, were tetraploid. On the other side, the epidermis was diploid and all the inner tissues were tetraploid.

**Inheritance of earliness of flowering in the sweet pea,** T. M. LITTLE and J. H. KANTOR (*Jour. Hered.*, 32 (1941), No. 11, pp. 379-383, fig. 1).—Based on the results of numerous crosses carried forward through several progeny generations, it is concluded that the early-flowering character in the sweet pea, *Lathyrus*

*odoratus*, is recessive to late flowering, and the difference is due to a single pair of alleles.

**Megagametophyte development in a triploid tulip**, J. M. BELLows, JR., and R. BAMFORD. (Md. Expt. Sta.). (*Bot. Gaz.*, 102 (1941), No. 4, pp. 699-711, figs. 43).—Studies of the Inglescombe Yellow tulip, a variety with 36 chromosomes in the somatic cells of the early nucellar layer and in the surrounding cells of the ovule and ovary, showed that the megagametophyte is of the *Fritillaria* type and that four divisions are necessary to form the mature gametophyte. Trivalents, bivalents, and univalents were observed during the meiotic prophase of the first division. The occurrence of lagging chromosomes and micronuclei was infrequent. There was an unequal separation of the chromosomes in both the meiotic and subsequent divisions.

**Abstracts of papers presented at the 1941 meetings of the Genetics Society of America: Cold Spring Harbor, New York, August 27-29, 1941; Dallas, Texas, December 29-31, 1941** (*Genetics*, 27 (1942), No. 1, pp. 129-176; also in *Genet. Soc. Amer. Rec.*, 10 (1941), pp. 129-176).—Abstracts of the following papers of interest to animal geneticists (*E. S. R.*, 85, p. 746) are included: Two Modifiers of Self (*S*) and White-Spotting (*s*) in Guinea Pigs, by M. R. Baker and H. L. Ibsen (p. 130) (Kans. State Col.); The Physiology and Inheritance of the Hemophilia-like Abnormality in Swine, by R. Bogart, M. E. Muhrer, and A. G. Hogan (p. 133) (Mo. Expt. Sta. coop. U. S. D. A.); Inheritance of Shape of Vaginal Orifice in the Mouse, by E. B. and H. B. Chase (p. 136) (Univ. Ill.); A Mutation Toward Normal Eyes in the Anophthalmic Strain of Mice, by H. B. Chase (p. 136) (Univ. Ill.); The Production of Somatic Mutations in the Pigeon With X-rays, by L. J. Cole and H. E. Finley (p. 138) (Univ. Wis.); Translocations in *Sciara*: Their Effect on Chromosome Behavior and Sex Determination, by H. V. Crouse (pp. 138-139) (Univ. Mo.); Genic Effects on Serum Proteins, by R. W. Cumley, M. R. Irwin, and L. J. Cole (p. 139) (Univ. Wis.); Genetic Problems of the Grouse Locust *Tettigidea parvipennis* Harris, by C. M. Good, Jr., and R. K. Nabours (p. 143) (Kans. Sta.); Dominant and Recessive Responses of the *Sd* Factor in Natural and Domesticated Fish Populations (p. 144), and A Third Primary Factor, *Sd*, for Melanomas in Hybrid Fishes (pp. 144-145), both by M. Gordon; On the Physiological Basis of Inherited Disease Resistance, by J. W. Gowen (p. 145) (Iowa State Col.); A Sexually Dimorphic Factor in the Pigeon, by W. F. Hollander (p. 146); Gene Interaction in *Peromyscus*, by R. R. Huestis (pp. 146-147); Heredity in Rat Caries, by H. R. Hunt, C. A. Hoppert, and W. G. Erwin (p. 147) (Mich. State Col.); On the Linkage Relations and Manifestation of Polydactyly in the Fowl, by F. B. Hutt and C. D. Mueller (pp. 147-148) (Cornell Univ.); Suggestive Evidence for Duplicate Action of Genes, by M. R. Irwin and R. W. Cumley (p. 148) (Univ. Wis.); Modifiers of the Sex-Linked Gene for Barred Feathers and Sex Identification in Newly Hatched Chickens, by R. G. Jaap (p. 149) (Okla. Sta.); A Cytological Study of the Embryonic Livers (16-18 Days) of Normal and Flexed-Tailed (Anemic) Mice, by R. J. Kamenoff (p. 150); The Taming Effect of Coat Color Genes in the Norway Rat, by C. E. Keeler and H. D. King (p. 151); Screw-Tail, a New Mouse Mutation, by T. Laanes and E. C. MacDowell (pp. 151-152); Genetic Selection for Low Fecundity in the Fowl, by W. F. Lamoreux, F. B. Hutt, and G. O. Hall (p. 152) (Cornell Univ.); A New Mutation of Fowl Affecting the Axial Skeleton, Especially in the Tail Region, by W. Landauer (pp. 152-153) ([Conn.] Storrs Sta.); A Genetic Study of the Pattern of the Vena Cava Inferior in the Rabbit, by C. W. McNutt and P. B. Sawin (p. 156); Preparation of a Nucleohistone From Mammalian Organs, and Direct Demonstration of Its Nuclear Origin, by A. W.

Pollister and A. E. Mirsky (pp. 160-161); Inheritance of an Eye Anomaly in the Albino Rat, by J. H. Quissenberry [Quisenberry] and S. O. Brown (pp. 162-163) (Tex. A. and M. Col.); Genetic Hermaphroditism in a Strain of Pigeons, by O. Riddle, H. H. Dunham, and J. P. Schooley (p. 165); Increased Viability of Homozygous Yellow Mouse Embryos in New Uterine Environments, by G. G. Robertson (pp. 166-167); Suppression of a Dominant Character, Polydactylism, in the Domestic Fowl, by P. D. Sturkie (p. 172) (Ala. Sta.); and A Case of Inherited Partial Sterility and Embryonic Mortality in the Rat, by E. Waletzky and R. Owen (p. 173) (Univ. N. C. and Wis.).

Some factors affecting fertility in swine, R. W. PHILLIPS and J. H. ZELLER. (U. S. D. A.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 439-442).—Among 1,354 sow-breeding seasons in several breeds, more than one-fifth failed to conceive. The difference, at least in part, was related to breed. Conception failed to occur in 13.9 percent of the Duroc-Jerseys and 36.9 percent of the Tamworths. Among all the sows bred it was calculated that only 27.1 percent of the ova developed into weanling pigs. The level of fertility in boars of different breeds was variable, as indicated by services per pregnancy, size of litter, percentage of offspring weaned, and proportion of abnormal pigs.

Tests for linkage in the guinea pig, S. WRIGHT (*Genetics*, 26 (1941), No. 6, pp. 650-669).—Continuing the study of linkage relations in the guinea pig (E. S. R., 60, p. 630), there was only one case of probable linkage between genes *R* and *Px* found in 21,867 recombination crosses exhibiting 10 characters from suitable backcrosses. "Genes *R* and *Px* gave recombination percentages of  $41.10 \pm 4.14$  percent in coupling data in females,  $39.29 \pm 9.45$  percent in repulsion data in ♀s,  $42.75 \pm 3.01$  percent in coupling data in ♂s,  $42.50 \pm 5.59$  percent in repulsion data in ♂s, and in the grand total  $42.08 \pm 2.17$  percent recombination or 3.65 times the standard error on the hypothesis of independence." It appeared that one of the three or four major factors responsible for normal polydactyly was probably linked with the agouti gene. No cases of partial or total sex linkage were found.

Linkage studies of the rat (*Rattus norvegicus*), V. W. E. CASTLE and H. D. KING. (Univ. Calif. et al.). (*Natl. Acad. Sci. Proc.*, 27 (1941), No. 8, pp. 394-398).—Loci in the albino chromosome (E. S. R., 85, p. 747) were established from the characteristics of 523 progeny of gray nonwaltzers of the constitution  $\frac{CpW}{cPw}$  mated to homozygous triple recessives and from studies by Grüneberg (E. S. R., 83, p. 181) as 0, 3.3, 3.8, 23.3, and 58.6 for the genes lethal (*l*), albino (*c*), red-eyed yellow (*r*), pink-eyed yellow (*p*), and waltzing (*w*), respectively. The loci of the genes in chromosome II were ascertained as curly (*Cu*), 0; anemia—a lethal (*an*), 2; and brown (*b*), 45. These loci were established from characteristics of the 1,370 progeny of triple heterozygotes of the genetic formula  $\frac{Cu\ an\ b}{++B}$  mated with animals homozygous for brown but heterozygous for anemia because of its lethal effect.

A case of spontaneous intersexuality in the rat, M. W. BURRELL, R. R. GREENE, and A. C. IVY (*Anat. Rec.*, 81 (1941), No. 1, pp. 99-117, pls. 2, fig. 1).—The anatomy of a spontaneously occurring intersexual rat is described. The animal possessed an ovary on the left side and a subperineal ovotestis on the right side. The secondary sex organs of both sexes were present.

Autosomal and sex chromosomal translocations and viability in *Apotettix eurycephalus* Hancock, R. K. NABOURS, F. M. STEBBINS, and W. R. B. ROBERTSON. (Kans. Expt. Sta. et al.). (*Jour. Expt. Zool.*, 88 (1941), No. 2, pp. 239-261, pl. 1, fig. 1).—Translocations of unequal portions of two autosomes and of chro-

matin and centromere from one autosome to the *X* chromosome in this species were induced by X-ray treatment. In the latter case an autosomal dominant color pattern was changed to a sex-linked character. Excesses of chromatin were deleterious to the viability of both sexes, but  $\delta$ s were less drastically affected than  $\phi$ s. The cytological observations were correlated with the genetical results.

**Genetic studies on *Chorthippus longicornis***, M. CREIGHTON and W. R. B. ROBERTSON (*Jour. Hered.*, 32 (1941), No. 10, pp. 338-341, fig. 1).—Four characteristic color patterns of *C. longicornis* were found due to a multiple allelic series designated as  $s^+$ ,  $s^V$ ,  $s^L$ ,  $s^R$ . Pattern of the British form of the same species are described.

**Polydactyl feet of two strains of chicks**, M. T. HARMAN and F. NELSON. (Kans. State Col.). (*Amer. Nat.*, 75 (1941), No. 761, pp. 540-549, figs. 10).—Anatomical differences and similarities between the two types of polydactyly in fowls noted by Warren (E. S. R., 85, p. 36) are presented.

**The "early lethal" action of the homozygous creeper factor in the chick**, J. M. CAIRNS (*Jour. Expt. Zool.*, 88 (1941), No. 3, pp. 481-503, pls. 2, fig. 1).—Study of embryos from the creeper stock of Landauer (E. S. R., 83, p. 475) showed the early lethal effect of the creeper factor to be localized in the circulatory system. Blocking of the vitelline artery of normals produced the same anastomosis of dorsal aorta-cardinal vein. The blood pressure increased in these vessels and caused a swollen condition. Intermediate stages cause phocomelic embryos which survived the fourth day of incubation. There still remains the uncertainty as to whether the circulatory disturbance precedes or follows the growth disturbance.

**Reciprocal crosses between the guinea and the domestic fowl**, R. D. OWEN. (Wis. Expt. Sta.). (*Jour. Expt. Zool.*, 88 (1941), No. 2, pp. 187-217, pls. 2).—There were produced 16 fertile eggs by mating roosters with guinea hens and 36 fertile eggs by mating guinea cocks with hens by the artificial insemination methods of Burrows and Quinn (E. S. R., 81, p. 773). Mortality of these embryos was very heavy. None of the guinea  $\delta \times$  chicken  $\phi$  embryos hatched, and of the 11 embryos from chicken  $\delta \times$  guinea  $\phi$  permitted to go through incubation only 1 hatched. In the former cross, about half of the embryos died in the primitive streak stage and about half died after the circulatory system had developed in a normal fashion. Embryonic death was not so complete a barrier in the cock  $\times$  guinea hen cross since dead embryos were found on the fourth day and from the fifteenth day of incubation to pipping of the egg. Evidently the two species are naturally kept separate by morphological and psychological barriers in addition to the low viability of the hybrids. Inadequate knowledge of the sex ratio of the guinea  $\delta \times$  hen hybrids because of the early mortality did not allow an analysis of differences in the mortality of the sexes. The ratio of seven  $\delta$ s to three  $\phi$ s in the reciprocal cross is considered to approximate equality. There were found to be abnormalities of the head region of the guinea  $\delta \times$  chicken  $\phi$  hybrids and structural abnormalities of the adult testis of the reciprocal cross which indicate a developmental imbalance.

**Bioassay of the growth hormone of the anterior pituitary**, W. MARX, M. E. SIMPSON, and H. M. EVANS. (Univ. Calif.). (*Endocrinology*, 30 (1942), No. 1, pp. 1-10, figs. 4).—Standard methods with hypophysectomized immature and normal  $\phi$ s 5 to 6 mo. of age served for study of the effects on body weight of different doses injected daily for 10- to 20-day periods. The relation between the logarithm of the daily dose and the body weight gain was expressed by a straight line, the slope characteristic of growth hormone preparations. Either type of test animal could be used, but each had limitations.

**The gonad-stimulating potency of the pituitary of hypothyroid young male rats,** K. F. STEIN and M. LISLE (*Endocrinology*, 30 (1942), No. 1, pp. 16-24).—The gonad-stimulating potency of the pituitaries of young ♂ rats were reduced at from 21 to 50 days after thyroidectomy. Histological study showed a decrease in the number and size of the eosinophiles with a corresponding increase in the number of chromophobes and basophiles. Observations were made on young thyroidectomized ♂s and the effects of their pituitary glands on ♀ litter mates. There were increases in weights of the ovaries and uterine tubes as compared with uninjected controls.

**Clinical observations on the use of equine gonadotropin in the mare and cow,** H. S. CAMERON. (Univ. Calif.). (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 778, pp. 60-62).—Of 9 mares and 46 cows which were treated with equine gonadotropin in an attempt to induce oestrus where the cycle was dormant, all of the mares responded within 10 days, whereas 25 cows failed to respond.

**Semen studies in the bull,** R. W. DOUGHERTY and H. P. EWALT. (Oreg. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 2 (1941) No. 5, pp. 419-426, figs. 7).—The chemical and physical characteristics are given of 645 semen samples from 103 bulls, together with reports of success in the artificial fertilization of cows. Refrigeration and chemical inactivation in the first few hours prevented the pH changes associated with lowered motility and viability. The ascorbic acid content of the semen samples varied from 0.22 to 8.15 mg. per 100 cc., but the relation to motility and viability, although suggested, was irregular.

**Phospholipids as a source of energy for motility of bull spermatozoa,** H. A. LARDY and P. H. PHILLIPS. (Wis. Expt. Sta.). (*Amer. Jour. Physiol.*, 134 (1941), No. 3, pp. 542-548, figs. 3).—Oxygen consumption of bull spermatozoa, as determined by methods employed in previous studies (E. S. R., 86, p. 316), was not appreciably increased by lecithin additions to a medium containing glucose. This is in agreement with previous conclusions (E. S. R., 85, p. 749) that the intracellular reserves of the spermatozoa are phospholipoid in nature.

**The rate at which spermatogenesis occurs in the rabbit,** S. A. ASDELL and G. W. SALISBURY. (Cornell Univ.). (*Anat. Rec.*, 80 (1941), No. 2, pp. 145-153, pl. 1).—When the testes were transferred from the scrotum of the rabbit, a short interval in the abdomen produced damage requiring a much longer time to repair. The rate of recovery after return to the scrotum was roughly proportional to its stay in the abdomen, although there was an unaccountable lag in the recovery of those that had been in the abdominal cavity for a long period. Those that were in the abdominal cavity for 4 or 5 days did not produce spermatozoa, even after 49 days, on being replaced in the scrotum. These results on sperm production in the rabbit are contrasted with that in the bull, ram, and boar.

**The viability of spermatozoa in the abdominal epididymis and the failure of motile sperms to fertilize ova,** S. A. ASDELL and G. W. SALISBURY. (Cornell Univ.). (*Amer. Jour. Physiol.*, 132 (1941), No. 3, pp. 791-795).—Anchoring the testes of mature rabbits to the ventral abdominal wall caused spermatogenesis to cease in 24 hr. Destruction of the fertility occurred in 8 days, and among 29 matings by ♂s with testes in the abdominal cavity for 9 or 10 days no matings were fertile. Although some motility was observed in one case up to 14 days, all of the 12 showed immotile sperm after 15 days in the abdomen. Motile but nonfertile sperm failed to survive to ovulation in ♀s after mating.

**Development of the testes and combs of White Leghorn and New Hampshire cockerels,** J. E. PARKER, F. F. MCKENZIE, and H. L. KEMPSTER. (Mo. Expt. Sta. coop. U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 1, pp. 35-44, figs. 3).—

The testicular weight of White Leghorn and New Hampshire cockerels increased at the same rate to 12 weeks of age, but at from 12 to 24 weeks the testes of the New Hampshires doubled their weight while White Leghorn testes increased sevenfold. However, from 24 to 30 weeks the testes of the New Hampshires increased almost five times in weight. Although the comb weights were about the same in the two breeds at hatching, at 4 weeks of age the Leghorn combs were more than twice as large and at 24 weeks were more than three times the size of the New Hampshire combs. At from 12 to 24 weeks the combs of the New Hampshires were about proportional to the body growth, but in the Leghorns the comb weights increased nearly twice as rapidly as body weights. From a histological standpoint there was remarkable similarity in the development of the two breeds. Mature spermatozoa were in the testes of two 12-week-old Leghorn and three New Hampshire cockerels. The diameter of the seminiferous tubules increased after 8 weeks, but final growth was somewhat later in the heavier breed. As to fertility, one 16-week-old White Leghorn cockerel fertilized one of the two ♀s with which he was mated. At 24 weeks of age, White Leghorn cockerels were generally successful in fertilization, but none of the New Hampshire cockerels were capable of fertilization until 24 weeks of age. The study was based on the comb, testis, and body weights in histological examination of the testes of 24 White Leghorn and 26 New Hampshire cockerels up to 475 days of age.

**Gonadotropic hormone in AP of male and female rabbits during growth,** A. J. BERGMAN and C. W. TURNER. (Mo. Expt. Sta.). (*Endocrinology*, 30 (1942), No. 1, pp. 11-15, figs. 4).—Because of the sensitivity of chicks in gonad weight increase studies to light and temperature variations, special care had to be exercised in the use of the chick for determinations of age changes in amount of gonadotropic hormone in the pituitaries of rabbits (I. S. R., 86, p. 670). In the ♂ rabbit the amount of the hormone per 100 gm. of body weight or per gland increased very rapidly until a body weight of about 2,500 gm. was attained. Testis weight increased over this period but continued to increase for a longer period. In ♀ rabbits the gonadotropic hormone in the pituitary increased rapidly at weights of from 500 to 1,500 gm. Ovarian weights increased slowly in animals weighing up to 3,000 gm. The gonadotropic hormone content of the ♂ anterior pituitary was about 70 percent greater than that of the ♀.

**Effect of sex hormones, separately and combined, on the proliferation and hydration of combs and cloacae of male chicks,** I. L. KOSIN and S. S. MUNRO (*Endocrinology*, 30 (1942), No. 1, pp. 102-106, figs. 2).—A "puffing" reaction was induced in the cloacal region of baby chicks by daily injection of testosterone propionate or oestradiol dipropionate. Comb growth was markedly stimulated by the androgen, but was little affected by the oestrogen. There was no synergistic or antagonistic effect of the two hormones administered together.

**Effects of estrogen on androgenic stimulation of the prostate and seminal vesicle of the rat,** R. R. GREENE and D. M. THOMSON (*Endocrinology*, 30 (1942), No. 1, pp. 85-89).—Daily treatments for 21 days with 50γ of testosterone propionate restored the prostate weight of castrate ♂s to about 200 gm., which nearly equaled that of uncastrated animals. Oestrogen alone caused some increase in the size of the prostates and a marked increase in seminal vesicles, but when administered with the testosterone its effectiveness was reduced.

**Pubertal increase in responsiveness to androgen in the male rat,** C. W. HOOKER (*Endocrinology*, 30 (1942), No. 1, pp. 77-84, figs. 6).—Rats castrated at birth exhibited their greatest responsiveness of the prostates to testosterone at the age of from 40 to 60 days. Larger doses of testosterone were required at

younger ages to show recognizable response in the accessory organs. Groups of rats castrated at birth were treated with different amounts of the testosterone at ages ranging from 10 to 120 days, and the weights and character of the prostates were determined at autopsy 6 days after injection.

**Difference in response of mice of different strains to human pregnancy urine**, K. P. HUMMEL (*Endocrinology*, 30 (1942), No. 1, pp. 74-76).—Tests of response of immature and adult ♀s of different strains to the Ascheim-Zondek test showed marked differences in the number of follicles produced. Differences in the response of immature and adult ♀s to an extract of the pregnancy urine suggested variations in the endocrine balances found in the strains.

**Factors underlying the failure of cyclic mating behavior in the albino rat**, J. L. BOLING, R. J. BLANDAU, B. RUNDLETT, and W. C. YOUNG (*Anat. Rec.*, 80 (1941), No. 2, pp. 155-171, pl. 1).—Study of 21 rats in which the occurrence of oestrus was irregular or absent led to the conclusion that the basic factor was a low threshold of sensitivity to oestrogen. The ovaries of about half of these animals were normal histologically, but they did not necessarily remain so, as indicated by the second ovary removed at a later date than the first. The different responses of the spayed ♀s to variable doses of oestrogen and progesterone served as the measure of oestrogen sensitivity. Deficiency of hypophyseal stimulation is considered responsible for the cases of abnormal follicle development and luteinization.

**The effects of lactation on the implantation of ova of a concurrent pregnancy in the rat**, R. H. KREHBIEL (Univ. Ill.). (*Anat. Rec.*, 81 (1941), No. 1, pp. 43-65, pl. 1).—No marked differences were found in the weights up to 20 days and the mortality of young rats suckled by nonpregnant animals or mothers in the second to the ninth pregnancy. The implantation time determined by successive laparotomies was  $16 \pm 1$  days prior to parturition. Delays in implantation dates occurred between 6 and 20 days after mating, but the extent of these delays did not appear to be dependent upon the number of young born or suckled during the first 4 to 5 days. A suckled litter of six or more may induce a delay in implantation, but each animal and pregnancy exhibited its reaction to each degree of mammary gland activity. Successive pregnancies tended to reduce the effects of lactation. The relative size of the dam and litter may determine the length of the latent period. Unilateral ovariectomy in mated dams prevented attachment of the ova when performed prior to implantation but had no effect on pregnancies that had progressed further.

**The production of deciduomata in the pregnant lactating rat**, R. H. KREHBIEL (Univ. Ill.). (*Anat. Rec.*, 81 (1941), No. 1, pp. 67-77, figs. 4).—Further studies<sup>3</sup> on the responses of the endometrium of unilaterally ovariectomized pregnant rats to electrical or needle stab stimuli showed fundamental differences in the decidual and deciduomal reactions produced.

**Influence of adrenal and sex hormones on the differentiation of melanophores in the chick**, H. L. HAMILTON (*Jour. Expt. Zool.*, 88 (1941), No. 2, pp. 275-305, pls. 2, figs. 2).—Studies of the effect of hormones on melanophore development in tissue cultures of skin ectoderm from New Hampshire Reds, Rhode Island Reds, and Barred Plymouth Rocks showed that testosterone, oestrone, and sesame oil increased the number of black melanophores from red breeds, whereas oestradiol and olive oil decreased them. Oestradiol, testosterone, and desoxycorticosterone inhibited the differentiation of black melanophores in explants from Barred Plymouth Rock embryos. Evidently the hormones may act as inhibitors or catalysts on the rate of melanin synthesis within the cell.

<sup>3</sup> *Anat. Rec.*, 73 (1939), No. 3, Sup. 2, pp. 32-33.

**Pregnancy diagnosis in swine by a chemical test.** S. Y. ROTH, D. T. MAYER, and R. BOGART. (Mo. Expt. Sta. and U. S. D. A.). (*Amer. Jour. Vet. Res.*, 2 (1941), No. 5, pp. 436-438, figs. 2).—A modified Cuboni test<sup>4</sup> is recommended for ascertaining pregnancy in the sow only between the twenty-first and thirty-second days of gestation. Therefore, breeding records must be available.

**Does a stimulation of the germinative epithelium of immature male rats occur after treatment with gonadotropic hormones, augmentative substance, androgens, and vitamin E?** B. ZONDEK, A. BRZEZINSKI, and F. SULMAN (*Endocrinology*, 30 (1942), No. 1, pp. 25-31).—Spermatogenesis was not produced in 20-day-old ♂ rats treated for 10 days with pregnancy urine prolan or gonadotropins from pregnant mare blood, anterior pituitary, menopause urine, and ♂ urine when fed a vitamin E-rich ration. Augmentation with cock serum also gave no acceleration of spermatogenesis. Some acceleration in spermatogenesis was induced by testosterone in combination with anterior pituitary gonadotropin and cock serum or ♂ urine gonadotropin and cock serum, but there was no sperm formation. The two combinations led to formation of sperm heads in 30-day-old rats. Evidently spermatogenesis in mammals is a more complex process than ovogenesis.

## FIELD CROPS

[Field crops research in the Bureau of Plant Industry]. (Partly coop. State expt. stas. et al.). (*U. S. Dept. Agr., Bur. Plant Indus. Rpt.*, 1941, pp. 2-5, 6-9, 10-11, 13-15, 15-16, 20, 21-22, 22-23, 23-24, 32, 33-34, 35-36).—Significant accomplishments and progress results are reported from breeding work with corn, wheat, oats, barley, seed and fiber flax, cotton, red and white clover, lespedeza, soybeans, peanuts, Kentucky bluegrass, orchard grass, bentgrass, potatoes, sugarcane, and sugar beets. Examples of the improvement work include U. S. Hybrid 13 corn, outstanding in productivity; hardy winter barleys and oats and spring oats, also disease-resistant; disease-resistant seed flax of improved seed and oil quality developed; dual-purpose grain and forage sorghums; a strain of alfalfa resistant to bacterial wilt; edible varieties of soybeans ranging from 75 to 165 days from planting to maturity, differing markedly in flavor and cooking quality, and either immune or highly resistant to attack of Mexican bean beetle; improved turf grasses, including bentgrasses, bluegrass, and fescue selections; potatoes resistant to leafhopper injury and a method of producing virus-free seed potatoes; U. S. 22 sugar beet variety improved in curly top resistance replacing older sugar beet varieties, and the leaf spot-resistant sugar beet variety U. S. 200×215 sugar beet for eastern districts; and sugarcane varieties potentially improved in disease resistance, cold tolerance, and other respects, and new sugarcane promising because of yield and other characteristics as apparent resistance to deterioration and loss of sugar when windrowed. Cultural experiments have demonstrated the superiority of September seedings of winter wheat in the Great Plains over earlier seeding as to foot rot damage; improvement of rice yields by rotation with pasture grasses and legumes; reduction in yield of rice due to turning under of rice straw more than overcome by addition of ammonium sulfate to the straw; importance of sucker stalks in grain sorghum production, as shown in variety-spacing tests; establishment of crested wheatgrass by seeding in the fall directly into weeds or stubble indicating an economical way to reclaim abandoned farm lands; Russian wild-rye (*Elymus junceus*) as potentially valuable for dry-farming areas of the

<sup>4</sup> Klt. Wehnschr., 13 (1934), No. 8, pp. 302-303.

northern Great Plains to supplement or to be used in a mixture with crested wheatgrass; merits of early planting of sugar beets in northern Great Plains; and manure and superphosphate in aiding establishment of kudzu. Other research dealt with crop production under irrigation; quality of irrigation and drainage waters; livestock and forage production contributing to stability of agriculture in the Great Plains; fertilizer and spacing studies on potatoes; cotton investigations, including use of X-ray in study and breeding of cotton, isolation of a strain of green lint cotton that has a wax content of from 15 to 17 percent (about 30 times as much wax as the ordinary white or cream-colored lint cottons of commerce), superior strains of cotton produced by in-breeding, cotton improvement in one-variety communities, influence of field and storage conditions on cottonseed vitality and composition, and promotion of sea-island cotton production in Florida and Georgia; production of abaci (Manila hemp) in the American Tropics; fiber flax studies; a detailed study of flue curing of tobacco from a biochemical viewpoint, temperature and humidity requirements, and modifications in conditions for different types and grades of leaf; control of bindweed by improved tillage methods; and sagebrush and shrub control in range improvement.

[Field crops research by the Georgia Station]. (Partly coop. U. S. D. A., Ga. Coastal Plain and Fla. Expt. Stas., et al.). (*Georgia Sta. Rpt. 1941*, pp. 15-24, 28, 52-55, 59-68, 78-89, 99-100, 102-105, 129, 130, 131, 135-137, 138-140, 144-148, figs. 10).—Investigations reported with field crops (E. S. R., 84, p. 33) at the station and Mountain Substation and outlying fields included breeding work with wheat, oats, cotton, peanuts, and potatoes; genetic studies with cotton; variety tests with corn, cotton, oats, wheat, soybeans, peanuts, cowpeas, sorgho for sirup, potatoes, sweetpotatoes, and winter legumes; comparative yields of corn and small grains; fertilizer experiments with cotton, corn, oats, sorgho, peanuts, soybeans, and pastures; a cotton variety-wilt-phosphorus study; cotton after cowpeas plowed under at different dates, after vetch, after sericea lespedeza, and after a general rotation, variously supplemented with fertilizers; delinting cottonseed on small experimental cotton gins; treatments for peanut seed; planting tests with soybeans and sweetpotatoes; green manure and size of seed tests and certification work with potatoes; variety, seeding, fertilizer, and harvesting tests with fiber and seed flax, and microscopical studies of flax fibers; pasture research, dealing with fertilizers and limestone for Bermuda-lespedeza pasture production, sources of P. single v. split applications of N for Bermuda grass and Bermuda grass plant studies, and seeding of Alyceclover in grain stubble following various methods of land preparation, and also in permanent pastures; and controlling weeds in small grains with Sinox spray.

[Farm crops research in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 4 (1941), No. 12, pp. 1-4, 5-6, 7-8, fig. 1; 5 (1942), No. 1, pp. 1, 2-3, fig. 1).—Reports of current progress are given in the following articles:

No. 12.—Corn Hybrids and Varieties Evaluated in Yield Tests at 7 Locations in State, by W. H. Freeman (pp. 1-3), and Delta Trials Result in High Corn Yields by Better Hybrids and Adapted Varieties, by P. W. Gull (p. 8). This number also contains brief reports by C. Dorman on agronomic work at sub-stations, including variety tests with cotton, corn and hybrids, oats, wheat, barley, sugarcane (coop. U. S. D. A.), potatoes, soybeans, and miscellaneous forage crops; a trial of Alyceclover; cultural (including planting tests) with cotton, corn, oats, Sudan grass, and lespedeza; fertilizer experiments with cotton, corn, oats, lespedeza, pasture, and summer and winter legumes; other pasture studies; yields of different crops after oats and cotton after various green manures v.

commercial nitrogen; soil improvement crops for corn and cotton; interplanting of corn with legumes; and crop rotations.

No. 1.—Cotton Varieties—Standard, New, and Improved—Tested at Five Locations in State (p. 1); Yields of Cotton Varieties in Tests by Hill Stations, by J. F. O'Kelly (p. 2); and Delta Yields of Standard, New Cotton Varieties, by H. A. York (p. 3).

Crop rotation studies, H. Y. CHEN and A. C. ARNY (*Minnesota Sta. Tech. Bul.* 149 (1941), pp. [1]+46).—Yields of crops grown continuously and in rotations, 1910–39, on Field T at University Farm (E. S. R., 38, p. 825) were compared, and a study made of the influence of rainfall and temperature on crop yields in these cropping systems.

Corn yields in rotations including clover-timothy hay crops usually significantly exceeded those of cropping systems omitting mixed hay crops. Corn in the corn-oat rotation averaged 3.55 bu. more than continuous corn. Yields of corn from the 3-, 4-, and 5-yr. rotations all containing mixed hay crops and manured were not significantly different. Manure in addition to rotations further increased yields. Effects of rotation and application of manure were additive. Oats yields were lower in manured continuous cropping and 2-yr. wheat-oats rotation than in other rotations. Alternating a cultivated crop with oats increased oats yields significantly, but including mixed hay crops in manured rotations did not raise oats yields materially. Manure in the 3-yr. rotation caused an increase of 3.69 bu. Effects of rotation and application of manure on oat yields were not additive. Wheat yields in the 3-, 4-, and 5-yr. rotations exceeded those of continuous wheat and the wheat-oats rotation. Hay yields in the rotations were increased by manure. Total digestible nutrients per acre produced by cropping systems containing corn or both corn and hay averaged higher than those produced by grains only, continuous or alternating with each other. Crop yields from the 3-, 4-, and 5-yr. rotations, all manured, were, in general, not significantly different. Yield differences of crops in these cropping systems were brought about largely in the first 10 yr. or less of operation, but did not change materially after this period.

Deficiency in rainfall in April resulted in reduced hay yields, and if the deficiency extended over both April and May the hay yields were reduced further and oats yields were lowered also. Deficient rainfall in July or in July and August limited corn yields, and if July and August temperatures were also unusually high, a further reduction occurred in yield. Subnormal temperatures during the entire or major part of the growing season resulted in low corn yields. Correlation coefficients indicated that on the average the corn, oats, wheat, and hay crops reacted similarly to precipitation and temperature under the different cropping systems during any given period.

While neither precipitation nor temperature during the growing season, according to the correlation coefficients, limited growth and yields of corn over the 30-yr. period, examination of yields and monthly rainfall and mean temperature for certain years showed that weather during the growing season often affected corn yields materially. Oats yielded highest during cool and moist seasons; cool weather appeared to be more important than high precipitation for oats. Wheat was similar to oats in its climatic requirements. Hay produced highest yields when the weather was cool and moist during its growing period, but contrary to results for oats the precipitation appeared to be more important than temperature to hay crops. For oats, wheat, and hay, precipitation and temperature became increasingly important to yields as the plants approached the flowering period.

**Grassland agriculture** (*U. S. Dept. Agr., Sec. Agr. Rpt., 1941, pp. 217-218*).—Factors causing and involved in the current trend toward a grassland type of farming in the United States are discussed briefly, with comments on merits of crested wheatgrass and Russian wild-rye; new strains of buffalo grass, Sudan grass, Bermuda grass, alfalfa, red clover, sweetclover, and soybeans; and the value of grass and legume forage and pasture in production of animal products and conserving farm labor, and of legumes in providing N for soil fertility.

**Pasture culture in Massachusetts**, W. G. COLBY (*Massachusetts Sta. Bul. 380 (1941), pp. 44, figs. 8*).—The historical background of pastures and soils in Massachusetts is reviewed, and an analysis is made of the principal agronomic factors involved in present-day pasture culture and management, i. e., the soil, grazing system, pasture plants, and the climate.

**[Legume and inoculation studies in Wisconsin]**. (Partly coop. U. S. D. A. et al.). (*Wisconsin Sta. Bul. 453 (1941), pp. 47-48, 64-65*).—Brief comments are made on the harvesting of clover seed with grain threshers and combines instead of clover hullers, by W. H. Ebling and F. V. Beck; improved culture media for bacteria for inoculating soybeans, by P. and J. B. Wilson and W. W. Umbreit; differences in ability of strains of root-nodule bacteria to fix N in association with different soybean varieties, by Umbreit and S. C. Fan; and similarity of N-fixing systems of root-nodule bacteria and *Azotobacter*, by P. Wilson, C. Lind, S. Lee, O. Olson, J. Wilson, and O. Wyss.

**Barley production in Texas**, I. M. ATKINS and P. B. DUNKLE. (Coop. U. S. D. A.). (*Texas Sta. Bul. 605 (1941), pp. 35, figs. 9*).—The adaptations, uses, cultural requirements, and diseases of barley in Texas are described, and report is made on results of variety tests at a number of field stations.

Barley fits into the rotation similarly to oats and wheat and is handled with like equipment. As a feed grain it is about equal to corn and grain sorghum but should be ground for livestock. Fall seeding of the Texas variety is recommended in central Texas and Wintex in the north-central part of the State. Spring seeding, less productive, is not advised unless winter-killing occurs. Throughout this area barley produces yields of grain equal to that of corn or grain sorghum, provides winter cover to prevent soil erosion, and produces abundant pasturage for livestock. On the high plains area of the Panhandle, barley may be either fall or spring sown. Fall seeding of Wintex or Tennessee winter types may winter-kill some seasons, but if they survive are more productive than spring-sown barley. In seasons of ample spring rainfall, barley is a desirable spring-seeded catch crop.

Varietal recommendations are Wintex and Texan for all of central Texas, and Wintex for fall seeding in the southern part of the Panhandle and Reno and Michigan Winter for the northern part. Stavropol, Coast, and Flynn are probably the more desirable varieties currently available for spring seeding in the Panhandle. Wintex, developed from a pure line selection of a local barley, and Texan, selected from a bulk hybrid, both by Atkins at the Denton Substation, have been among the most productive varieties from fall seeding at the Denton, Temple, Iowa Park, Chillicothe, Amarillo, and San Antonio Substations. Texas is recommended above Wintex for the Temple area. Both produce high yields of grain and high test weight and are adapted to either fall or spring planting. Texas has the additional advantage of a smooth awn.

**Spring oat varieties for Illinois**, G. H. DUNGAN, O. T. BONNETT, and W. L. BURLISON (*Illinois Sta. Bul. 481 (1942), pp. 441-471, figs. 7*).—The oats varieties producing the most grain among those grown for 3 yr. or longer in tests in northern Illinois (DeKalb and Mt. Morris) were Marion, Iowar, Albion, Richland, and Gopher; in central Illinois (Urbana) Marion, Columbia, Boone, Kanota,

and Gopher; and in southern Illinois (Alhambra) Brunker, Columbia, Burt, Markton X Rainbow, and Marion. Columbia could be considered the best all-round variety for southern Illinois until new varieties demonstrated their superiority. Varieties that yielded the most grain in northern and central Illinois usually produced less than average yields of straw. The reverse was true in southern Illinois where the average yield of straw is low. Percentage of groats, shown for several varieties, is deemed a better measure of quality in oats than weight per bushel. Marion averaged highest in yield of groats per acre of any variety in the tests, 1930-41.

Gopher oats drilled at the rate of 8 pk. an acre gave the highest yields. Broadcasting 10 pk. per acre gave as good yields as drilled seeding at this rate. Drilling oats in 16-in. rows resulted in lower yields than drilling them in 8-in. rows, but the wider space between drill rows favored the growth of clover.

Recommended growing practices are outlined.

**Influence of temperature on the response of *Arachis hypogaea* L. to day-length.** A. I. CHELIADINOVA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 31 (1941), No. 1, pp. 55-57*).—From the data presented it is concluded that no photoperiodic treatment of the peanut plant will accelerate its development unless temperatures continue favorable during the preflowering period. The number of flowers developed on the short-day plants might be equal to or higher or even lower than on long-day plants, but the ratio of fertilized flowers was always higher on the former. The ratio of fertilized flowers also increased with rise in temperature, the latter being even more effective than day length. The yield of fruit likewise rose with the temperature.

**Influence of illumination intensity upon the response of peanuts to daylength.** A. I. CHELIADINOVA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 31 (1941), No. 3, pp. 276-278*).—Two varieties of peanuts were grown under natural and 10-hr. day length and under two degrees of shading, as compared with controls under natural day length and no screening. Toward the end of the growing period, the controls had two to three times the number of blooms, but the treated plants, and especially those on the shorter photoperiods, had far less numbers of underdeveloped pods and genophores than the controls. This was due to the fact that flowering took place earlier and sufficient time and nutrients were present to develop the fruits that had set. Screening with one or even two layers of gauze had no influence on the formation of green weight, which was affected only by the photoperiod, the short-day plants being much lower in green mass than the controls. It is believed that this character of high yields under partial shade can be turned to good account in mixed plantings where sufficient soil nutrients and water are available.

**New methods for breaking dormancy in recently harvested potato tubers.** T. S. TER-SAAKIAN (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 31 (1941), No. 2, pp. 165-167, fig. 1*).—According to the method described, the soil in a trench is moistened (but not to the saturation point), filled with newly harvested potatoes from the early crop, and covered with a layer of straw over which a layer of soil, moistened before or afterward, is placed. In such a trench the July temperature was about 25°-30° C. in the Armenian regions where these experiments were conducted, the tubers sprouted in 12-15 days, and, when planted in moist soil, they produced a second high-yielding crop during the same season.

**Agricultural seed.** A. S. LUTMAN (*Vermont Sta. Bul. 477 (1941), pp. 16*).—Purity and germination guaranties and variations therefrom are tabulated and discussed from tests of 463 samples of field crop seeds and forage mixtures obtained from local dealers in Vermont during 1941.

## HORTICULTURE

[**Horticultural studies by the Bureau of Plant Industry**]. (Partly coop. Calif. Expt. Sta.). (*U. S. Dept. Agr., Bur. Plant Indus. Rpt., 1941, pp. 10, 12, 18-19, 20-21, 22, 23, 24-25, 27*).—Included are brief reports of studies upon the possibilities of domestic production of drug plants, promising types of safflower for oil seed production, improvement of hops, varieties of grapes for the southern Great Plains area, harvest sprays for apples, control of biennial bearing in apples by spraying, the potash requirements of peaches, descriptions of four new strawberries, the timing of irrigations in citrus orchards, selection of promising types of tung trees, revitalization of old filbert orchards, breeding of curly top-resistant vegetables, lettuce breeding, tomato breeding, the development of powdery mildew-resistant melons, testing of ornamental shrubs suitable for the central Great Plains, the development of apple and peach rootstocks from domestic sources, refrigeration of citrus under shipment, nutrient requirements of citrus trees, the fertilization of pecan trees, mushroom investigations, and rubber investigations in Latin America.

[**Horticultural studies by the Georgia Station**] (*Georgia Sta. Rpt. 1941, pp. 129, 130, 131-134, 137-138, 141-144, figs. 4*).—Included are brief statements of progress on squash and collard breeding, fertilization and spacing of asparagus, use of starter solutions for pimiento peppers, factors affecting the longevity of peaches, cover crops for peach orchards, growth of peach roots, rootstocks for northern-type grapes, varieties of strawberry and bramble fruits, and varieties of dahlia.

Studies reported from the Mountain Substation include the culture of herbs; variety tests of peaches, cherries, and grapes; the effect of Korean lespedeza cover crops on grapevines; fertilization and culture of Tendergreen beans; fertilizer and variety tests with cabbage; fertilizer and cultural tests with tomatoes; and varieties, culture, and fertilizers for lettuce.

**Varieties and culture of fruits and vegetables**, C. DORMAN (*Miss. Farm Res. [Mississippi Sta.], 4 (1941), No. 12, pp. 4-5, 5, 6*).—Information is presented on the yields of bean, tomato, peach, apple, and pear varieties and on the results of spacing and pruning tests with tomatoes at the Delta Substation and upon fertilizer studies with cabbage and string beans at the South Mississippi Substation.

[**Horticultural studies at the Truck Crops Substation**], C. DORMAN (*Miss. Farm Res. [Mississippi Sta.], 4 (1941), No. 12, pp. 6, 7*).—Included are brief reports on variety and fertilizer studies with cabbage and cauliflower; variety, breeding, and fertilizer trials with tomatoes and English peas; and varieties and breeding of snap and lima beans and sweet corn.

**Relation of certain air temperatures and humidities to viability of seeds**, L. V. BARTON (*Contrib. Boyce Thompson Inst., 12 (1941), No. 2, pp. 85-102, figs. 5*).—Various species of seeds were subjected to four constant temperatures, 5°, 10°, 20°, and 30° C., with relative humidities of 35, 55, and 76 percent at each temperature. In order of increasing water absorption were the peanut, lettuce, flax, pine, tomato, and onion. With a relative humidity of 35 percent seeds absorbed about the same amount of water at 5° and 10°, but in every case less water was absorbed at the higher temperatures of 20° and 30°. At 55 and 76 percent relative humidity, the peak of moisture absorption was at 10° and the lowest at 30°. Seeds of high initial vitality were much more resistant to unfavorable environments than those of low vitality. Deterioration, once under way, proceeded rapidly under unfavorable storage conditions. Seeds stored in the open laboratory attained a moisture content in August approximately

double that of midwinter. Such changes are believed to contribute to the deterioration of seeds in open storage.

**Effect of several growth substances on vegetable crop plants, E. C. MINNUM.** (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 477-478).—Treatment of the seeds and plants of various vegetable crops with certain of the indole acids in the form of dusts and aqueous solutions resulted in no benefit and in some cases was harmful.

**Lanolin emulsions as carriers of growth substances, R. L. WINKLEPLECK and J. A. MCCLINTOCK.** (Purdue Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 94-96).—Information is presented on the preparation and use of lanolin emulsions for the stimulation of root formation in cuttings. Triethanolamine was found a very satisfactory emulsifying agent, both from the standpoint of ease of preparation and stability of the finished emulsion. A formula that will produce a smooth, nearly white emulsion which remains stable almost indefinitely at room temperature required 38 gm. of lanolin, 7.5 gm. of stearic acid, 2.7 gm. of triethanolamine, and 100 gm. of distilled water. The growth-promoting substance should be dissolved in a suitable solvent and the solution added slowly to the emulsion with constant stirring.

**Effect of vitamin B<sub>1</sub> on the yield of several vegetable crop plants, E. C. MINNUM.** (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 475-476).—None of several treatments applied in connection with starter nutrient solutions to various vegetable crops grown at Ithaca and near Albany, N. Y., had any significant effect on growth. The author suggests that cold, wet weather in May and June may have been a factor in the negative results.

**Further tests with vitamin B<sub>1</sub> on established plants and on cuttings, A. E. HITCHCOCK and P. W. ZIMMERMAN** (*Contrib. Boyce Thompson Inst.*, 12 (1941), No. 2, pp. 143-156, figs. 3).—China-aster plants growing in flats during February and March produced somewhat taller plants of greater fresh weight when supplied weekly with a solution of vitamin B<sub>1</sub>. Potted plants supplied B<sub>1</sub> in June and July showed no response. Application of B<sub>1</sub> every 3 to 5 days to the sand in which various species of cuttings were placed did not accelerate the development of roots. In a few cases vitamin B<sub>1</sub> appeared to increase the activity of indolebutyric acid. The results suggested that vitamin B<sub>1</sub> should not be recommended for practical use in treating cuttings or as a soil amendment.

**Probable causes for the difference in facility of producing parthenocarpic fruits in different plants, F. G. GUSTAFSON** (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 479-481, figs. 2).—Upon extraction with ether or methanol, the more compact ovaries of the tomato, pepper, and cucumber were found to contain more native auxin than ovaries of the more bulky and watery squash, pumpkin, and watermelon. Since crookneck and Buttercup types of squash produced parthenocarpic fruits with chemical treatment, the author concludes that at present it cannot be said that there is any relation between natural auxin of the ovary and the ease with which parthenocarp may be induced. Of the four chemicals used, naphthaleneacetic acid was the most effective.

**Breeding better vegetables for the South (U. S. Dept. Agr., Sec. Agr. Rpt., 1941, pp. 219-220).**—Recent progress at the Regional Vegetable Breeding Laboratory at Charleston, S. C., is referred to.

**First need of early greens is nitrogen, L. R. FARISH** (*Miss. Farm Res. [Mississippi Sta.]*, 4 (1941), No. 12, pp. 1, 3).—Significant increases in the yield and quality were obtained from early spring applications of nitrate of soda to spinach. In the spring of 1938 the yields from the plats with no fertilizer, with 300 lb. of nitrate of soda per acre, and with 240 lb. of ammonium sulfate per acre were, respectively, 1,200, 10,200, and 8,000 lb. per acre. Apparently

after winter leaching the soil is particularly low in nitrates and responds readily to application of nitrate fertilizers.

**Effect of boron on plant growth and dry seed yield in lima bean** (*Phaseolus lunatus* L.), R. E. WESTER and R. MAGBUDER. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 472-474).—Applications 1 week before bloom of boric acid at the rates of 5, 10, and 15 lb. per acre to lima beans growing on a well-drained gravelly loam soil, fertilized liberally with commercial materials, resulted in significant increases in yield of dry beans in the 10- and 15-lb. treatments. The maximum yield of dry beans was produced on the 15-lb. plot. There was no significant effect on stand of plants or on the green weight of plants. Determinations at the end of the season of the pH of the soil showed no significant differences related to boric acid treatment.

**Wisconsin sweet corn canning trials**, W. B. ENNIS, R. H. ANDREW, and N. P. NEAL (*Canning Age*, 22 (1941), No. 13, pp. 612-613, 632).—Tabulated information is presented on the results of trials of the principal varieties and hybrids of sweet corn tested in 1941.

**Sweet corn in Alberta**, J. S. SHOEMAKER and C. WALKOF (*Alberta Univ. Col. Agr. Bul.* 38 (1941), pp. 75, figs. 21).—Comprehensive information is presented on the botany and history of sweet corn, types and varieties, hybrids and their production, characteristics of the corn plant and ear, pollination processes, climate and soil requirements, culture, picking maturity, seed production, breeding, food values, etc.

**New corn hybrids**, W. R. SINGLETON. (Conn. [New Haven] Expt. Sta.). (*Canning Age*, 22 (1941), No. 12, pp. 559-560, figs. 4).—In this account of sweet corn breeding activities, the author discusses certain new promising hybrids with respect to their parentage, plant and ear characteristics, quality, and potential uses.

**Crisp-head lettuce in Florida**.—A preliminary report, J. R. BECKENBACH, F. S. JAMISON, R. W. RUPRECHT, and F. S. ANDREWS (*Florida Sta. Bul.* 365 (1941), pp. 19, figs. 5).—Of a number of crisp-head strains of lettuce tested on several soil types in the State, Imperial No. 44 was found most promising because of a lower tendency to bolting and a capacity to form marketable heads under Florida conditions. The nitrogen requirements for the crop when grown on sandy soils ranged from 60 or 90 lb. of actual nitrogen per acre. Requirements for phosphorus and potassium were highly variable, dependent upon the conditions and the previous use of the soil. Sulfate of ammonia and urea were good nitrogen sources for slightly acid or alkaline soils. Natural organics, such as Milorganite and guano, that decompose fairly rapidly were excellent when not more than 40 percent of the total nitrogen was derived from such sources. Natural organic materials, such as castor pomace, were not found desirable because lettuce is a short-season crop and is grown during relatively cold weather when microbiological activity is relatively slow. As a result of a spacing experiment with Imperial 44 lettuce, it is recommended that such lettuce should not be set closer than 14 by 14 in.

**The effect of culture solution temperature on water intake and wilting of the muskmelon**, G. J. RALEIGH. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 487-488).—Delicious muskmelon plants were grown in cultural solutions held in Pyrex jars surrounded by water maintained at 50°, 65°, and 80° F. The air temperature was held at approximately 90°. Plants with roots at 50° wilted badly and those at 65° drooped slightly. The plants in the three groups used an average of 47, 160, and 285 cc. of solution, respectively, in 1.5 days.

**Nodulation and dry weight of garden peas as affected by sulfur and sulfates**, H. Z. GAW and P. N. SOONG (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 1, pp. 100-103).—Garden peas growing in pots of washed river sand and inoculated about the time of germination with pure cultures of nodule bacteria were supplied with different sulfates in addition to the basic nutrient solution. Calcium sulfate and iron sulfate increased nodule production and dry weight; ammonium sulfate increased dry weight but not nodulation; sodium sulfate and zinc sulfate increased nodulation but did not affect dry weight; and copper sulfate, chromium sulfate, and potassium sulfate depressed nodule formation and dry weight. Sulfur in its elemental form stimulated nodule production but depressed dry weight slightly.

**Some effects of calcium and pH upon spinach**, R. A. SCHBOEDER (Mo. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 482-486).—Long Standing Bloomsdale spinach was grown at five calcium levels at pH 5.2 and pH 6.8. The addition of increasing amounts of calcium to the quantity of calcium on the original subsoil resulted in an increase in both total fresh weight and dry weight. Both weights were significantly greater in the pH 6.8 than in the pH 5.2 series. The calcium in 19 gm. of dry weight increased as calcium was added, particularly in the pH 5.2 series. The total amounts of calcium in the crop increased as calcium was added. The amount of phosphorus in 10 gm. of dry weight increased with calcium additions up to the point where 6 milliequivalents per plant were added. The peak of phosphate content at pH 5.2 was 22 percent greater than the peak at pH 6.8. The total potassium content in the crop increased as calcium was increased in both pH series. The total quantity of magnesium and strontium was increased as the calcium was increased. The total amount of manganese in the crop was definitely increased by calcium additions at the pH 5.2 level but very slightly decreased at the pH 6.8 level.

**Studies of the tomato in relation to its storage.—II, The effects of altered internal atmosphere upon the respiratory and ripening behavior of tomato fruits stored at 12.5° C.**, K. A. CLENDENNING (*Canad. Jour. Res.*, 19 (1941), No. 12, Sect. C, pp. 500-518, figs. 19).—In this second paper of the series (E. S. R., 79, p. 480), the author reports that the so-called anomalous type of respiration, in which stored tomatoes ripened slowly and unevenly without an attendant rise in carbon dioxide output, was observed in fruit of plants grown at different seasons and under different light intensities in a single season. The condition was induced also by the careful sealing of the stem end scar with hot paraffin wax. When the wax was removed, there was a return to normal ripening and respiratory behavior. Waxed tomatoes were found subject to several physiological disorders, and if waxing was done when the tomatoes were in the yellow or yellow-orange stage they became soft and highly susceptible to fungal attack before attaining full color. It is suggested that wax should be applied before ripening has commenced if softening is to be avoided. In fact, the author deems it inadvisable under the present status of knowledge to recommend wax applications to the stem scars as a commercial practice, but suggests that tomatoes may be held satisfactorily for 5 weeks by storing at the mature green stage with the stems attached, at a temperature of 10°-12.5° C. and at a relative humidity of 80-85 percent.

**A physiological study of growth and fruiting of the tomato, *Lycopersicon esculentum*, with reference to the effect of certain climatic and edaphic conditions**, H. L. STIER (*Md. Univ. Off. Pub.*, 37 (1940), No. 9, pp. 35, 36).—An abstract of a doctorate thesis.

**Extra care to orchard after the '41 crop**, T. E. ASHLEY (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 1, pp. 1, 3).—Information is presented on the

winter and early spring care of fruit trees, particularly dormant spraying, pruning, fertilization, and control of borers.

**Cultural practices for young apple trees**, E. P. CHRISTOPHER. (R. I. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 181-183).—Inclusion of a 12-qt. pail of moist peat, with the soil placed about the roots of 1-yr. McIntosh and Baldwin trees at the time of planting had no significant effect on their growth in the first 2 seasons following setting as compared with similar trees given cultivation only. The best development, as indicated by trunk girth and shoot growth, was in trees mulched with 3 to 4 in. of rye straw and nonlegume hay. Trees in unfertilized pastures and in quackgrass made the poorest growth of all. Clean cultivation plus a cover crop of winter rye was next to the best. No fertilizer was applied in any case, and no pruning was done.

**The influence of leaf-fruit ratio on alternate bearing in the apple**, T. SHEN. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 127-132).—Thinning experiments carried on for two successive years on ringed branches of McIntosh, Red Delicious, Golden Delicious, and Wealthy trees showed in the first season a highly significant correlation between leaf-fruit ratio and fruit bud differentiation in three of the varieties. It was evident that somewhere between 700 and 1,399.9 cm.<sup>2</sup> of leaf area per fruit there is a point beyond which further increase in leaf area does not increase fruit bud differentiation. There were varietal differences in the optimum ratio. After July 10, thinning of fruit had no effect on fruit bud differentiation. In the second year, using the same branches, fruit bud formation was little influenced by leaf-fruit ratio and earliness of thinning. The author suggests that, even with a second ringing, the composition of the branches was probably not comparable to that of unringed branches. Possibly nitrogen was deficient in the ringed branches. It is suggested that the amount of bloom in the second season had a greater influence on fruit bud formation than any other factor. Apparently leaf-fruit ratios, which are chiefly concerned with carbohydrate supply, are not always the deciding factor in fruit bud formation. Water, nitrogen, and perhaps some unknown substance may become more important.

**Relative carbohydrate and nitrogen concentration in new tissues produced on ringed branches**, A. E. MURNEEK. (Mo. Expt. Sta.). (*Amer. Soc. Hort. Sci., Proc.*, 38 (1941), pp. 133-136, figs. 3).—Studies of the composition of spurs collected at different dates from ringed and unringed branches of Rome Beauty and Ingram apple trees showed that despite the increased set of fruit on the ringed branches the comparative concentrations of starch, sugars, and nitrogen in the flowers or fruit and in the current season's growth (exclusive of leaves) all followed the usual seasonal changes for such substances. The actual content of carbohydrates was higher and that of nitrogen lower in both fruit and spurs of ringed limbs. In the case of late-ringed Rome Beauty limbs, the differences were small or absent, yet fruit setting was increased just as much as by early ringing. Carbohydrate accumulation is apparently associated with the growth and development of the apple from a period when the second or third drop occurs until the time of fruit maturity. Immediately following pollination and fertilization, fruit setting and development are greatly influenced by nitrogen. It is suggested likely that growth substances of some kind may be the real regulatory agents and that nitrogen, carbohydrate, and other foods may serve merely as substrates for these materials. Ringing may cause a retention of such growth substances above the wound.

**Effect of scoring and of a-naphthyl acetic acid and amide spray upon fruit set and of the spray upon pre-harvest fruit drop**, C. L. BURKHOLDER and M. McCOWN. (Ind. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941),

pp. 117-120).—In May 1940, 14-year-old Starking apple trees, which had failed to set a full crop of fruit up to that time, were subjected to two treatments—scoring, and spraying when in full bloom. The scoring treatment resulted in only slight increases in the percentage of clusters setting fruit. Moderate decreases in set followed the application of full-blossom sprays containing 0.001 percent of  $\alpha$ -naphthylacetic acid or 0.005 percent of  $\alpha$ -naphthylacetamide. A very heavy decrease in set followed the use of a 0.005 percent  $\alpha$ -naphthylacetic acid on open flowers and was accompanied by serious injury to leaves. No injury was observed on trees receiving the 0.005  $\alpha$ -naphthylacetamide spray, and some injury occurred from the 0.001 percent  $\alpha$ -naphthylacetic acid. The use of harvest sprays materially reduced the dropping of mature fruit from Rome Beauty and Delicious trees, but no very significant results were obtained with McIntosh and Jonathan. The fact that varieties in which the initiation of abscission in bark tissues generally precedes pith abscission respond most readily to preharvest sprays suggests an important relationship between the manner of abscission and the reaction to such sprays.

The use of naphthaleneacetic acid and its derivatives for preventing fruit drop of apple, A. E. HITCHCOCK and P. W. ZIMMERMAN (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 104-110, figs. 2).—In trials with five varieties of apples, preharvest sprays gave good results in reducing dropping in some cases but not in others. Besides the varietal factor there were differences between trees of a single variety and between branches of a single tree. None of the derivatives of naphthaleneacetic acid used was noticeably more effective than the others. Concentrations of 25-50 mg. per liter appeared no more effective than concentrations of 7.5-15 mg. per liter. The season of 1940 was favorable for the early coloring and maturing of red-fruited apples, such as McIntosh, Stayman Winesap, and Baldwin, and the crop could have been harvested in most cases before a 20-percent drop occurred. It is suggested that the cool weather, although favorable for early coloring, may have limited the action of growth-reducing substances in limiting drop.

Spraying for control of pre-harvest drop of apples in New Mexico, J. V. ENZIE and G. W. SCHNEIDER (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 99-103).—In 1 year's experiments on 14-year-old Stayman Winesap trees, both naphthaleneacetic acid and naphthaleneacetamide, used at the approximate strength of 0.001 percent, were effective in delaying the preharvest dropping of fruit. The naphthaleneacetic acid was the more effective substance of the two. The materials were effective for a period of at least 15 days after the first application. A second spray was not as durable, possibly because of lower prevailing temperatures. The sprays were effective in reducing the drop of codling moth-infested apples, but not to the extent that handling costs were appreciably increased.

Further studies with sprays in controlling pre-harvest drop of apples, L. P. BATJER and P. C. MARTE. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 111-116, figs. 3).—In experiments with Williams apples hormone sprays were highly effective in retarding dropping, but it was noted that if the fruits were not harvested within a day or two after they would have dropped normally they became overripe and mealy. Naphthaleneacetic acid and naphthaleneacetamide were the only materials found highly effective. Sodium thiocyanate produced the only noticeable effect on color, the fruit having a decided pinkish cast. This chemical hastened maturity and also caused some spray injury in the form of brown flecks on the apples. One spray of naphthaleneacetic acid gave good results with McIntosh, the effects lasting for from 10 to 12 days when the spraying was accurately timed. Good results were obtained with Delicious

and Stayman Winesap, but not with York Imperial and Rome Beauty where dropping was severe despite the sprays. In Stayman Winesap and Delicious water core became a serious factor if the fruits were not harvested soon after the normal harvesttime. Apparently, with many varieties, preharvest sprays will have their greatest value in preventing dropping losses before and during the normal harvest period.

**Harvest sprays in Ohio, 1940,** C. W. ELLENWOOD and F. S. HOWLETT. (Ohio Expt. Sta.). (*Ohio State Hort. Soc. Proc.*, 74 (1941), pp. 67-73).—In the fall of 1940 five commercial materials, all having naphthaleneacetic acid as the active agent, and a home-made mixture with the same base were compared as preharvest sprays for Jonathan and Stayman Winesap trees. In one of the materials naphthaleneacetamide was used to supplement the naphthaleneacetic acid. No consistent differences were found between the several materials. Time of spraying was highly important, as indicated by the fact that Jonathan trees sprayed on October 4 dropped no more apples than did trees sprayed twice, September 27 and October 4. Unfavorable results were obtained with the Baldwin apple, apparently due to premature dropping of leaves as a result of leaf spot injury. Observations on McIntosh trees indicated that the delay in harvest from spraying permitted an improvement in the color of the fruit. Thorough and timely spraying was essential to success.

**Some responses of apples in storage to plioilm liners and wrappers,** H. H. PLAGGE and T. J. MANEY. (Iowa Expt. Sta.). (*Ice and Refrig.*, 101 (1941), No. 2, pp. 201-205, figs. 2).—The packing of Jonathan and Starking apples in plioilm-lined boxes resulted in a fairly constant, though not very high, concentration of carbon dioxide within the package over a 4-mo. storage period. This was sufficient to influence the metabolism of the fruit as measured by differences in appearance, firmness, and taste. Jonathan apples, after storage, were firmer, brighter in color, and much less affected by Jonathan spot than were check fruits in paper-lined boxes. Starking apples, on the contrary, were mealy after storage in plioilm and were in prime condition in the paper-lined boxes. At 31° F. the plioilm wrappers reduced the amount of soggy break-down in Winter Banana apples and delayed their ripening, while at 35° the amount of scald was reduced but ripening was not retarded. The wrappers increased the amount of scald in Paragon and York Imperial apples at 35°. When oiled papers were used with plioilm, the tendency toward scald was lessened. Jonathan apples, overmature at picking, had less scald when wrapped in plioilm, but not to an extent for commercial control.

**Extent of colored area on Elberta peaches in relation to leaf area per fruit and to fruit size,** C. F. KINMAN. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 58 (1941), pp. 191-192).—Fruits of branches ringed a few days after petal-fall were thinned to ratios of 10, 20, 30, 40, and 60 leaves per fruit. The ringed surfaces were kept open during the season. Measurements of the solid red areas on the fruits harvested when eating-ripe or nearly so showed an inverse relationship between color and leaf area. For example, the percentage of red area was approximately one-third as great for fruits with 60 leaves as for those with 10 leaves. The average weight of fruits with 60 leaves was three times that of fruits with 10 leaves. Covering fruits with black cloth inhibited red color formation, both on ringed and unringed branches.

**Sortenkundliche Untersuchungen an *Prunus domestica*** [Horticultural varieties of *Prunus domestica*], K. RÜDER (*Kühn-Arch.*, 54 (1940), pp. 1-132, figs. 155).—Herein are presented the results of an intensive study of the flowers, fruit, leaves, 1-yr. shoots, tree form, and roots of a large number of European plums and prunes. Among characters found highly constant and of great

value in distinguishing varieties were the form and markings of the pit or stone and the form of the buds on dormant 1-yr. shoots. The stone, the fleshy part of the fruit, the flowers, and the dormant 1-yr. shoots were sufficient for identifying varieties.

**Use more mulch on everbearers, W. G. BRIERLEY.** (Univ. Minn.). (*Minn. Hort.*, 69 (1941), No. 7, p. 130).—The exposure of potted strawberry plants to below freezing temperatures, after being allowed to mature and harden, showed more killing of autumn-fruiting kinds at the four temperatures used, i. e., 10°, 16°, 21°, and 27° F., than of the June-fruiting varieties. The reduced resistance of the autumn bearers is attributed to the fact that autumn fruiting lessens the quantities of reserve foods and probably delays maturity in other directions.

**Control of grape diseases and insects in eastern United States, J. B. DEMAREE and G. A. RUNNER** (*U. S. Dept. Agr., Farmers' Bul. 1893* (1942), pp. II+28, figs. 21).—This supersedes Farmers' Bul. 1220 (E. S. R., 46, p. 235).

**Effect of mulches and fertilizers on yield and survival of the dryland and highbush blueberries, A. KRAMER, E. L. EYINGER, and A. L. SCHRAEDER.** (Md. Expt. Sta. coop. U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 455-461).—Six mulching and cover crop treatments in 1939 and four fertilizer treatments in 1939 and 1940 were carried out with varieties of highbush blueberries and with naturally occurring plants of the dryland blueberry. Mulching decreased the survival of dryland blueberries, but increased the yield of both highbush and dryland plants. Peat mulch was particularly effective in increasing yield and root growth. Ammonium sulfate and complete fertilizer had little effect on increasing survival, but did improve yields. Burying the mulch, especially peat, alongside the roots improved survival and yield. Peat-sawdust mulch and lespedeza gave the best control of erosion, but lespedeza decreased blueberry yields.

**The effect of soil temperature on the growth of cultivated blueberry bushes, J. S. BAILEY and L. H. JONES.** (Mass. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 462-464, fig. 1).—Observations on nursery-grown Rubel blueberry plants placed in containers of soil, the temperature of which was held constant at desired points, showed that soil temperature influenced greatly the growth of plants, despite the fact that the air temperature was favorable. At the minimum soil temperature of 55° F., there was wilting of the tops at first but within a few days the plants became adjusted. In general, the average height and average total linear growth increased with rise in temperatures up to the maximum temperature used—90°. Above 65° the plants appeared to grow tall and upright in habit, and below 65° they were short and spreading.

**The limitations of *Chaenomeles lagenaria* *Wilsonii* as a horticultural plant, G. L. SLATE.** (N. Y. State Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), p. 471).—Because the plants were lacking in hardiness and were unproductive and the fruits had little value in jelly making, the author concludes that the species has very limited economic importance.

**El cultivo del cacao [The culture of cacao], E. LLANO GÓMEZ** (*Agricultura [Bogotá]*, 12 (1940), No. 24-25, pp. [1]+847-922, pls. 5, figs. 13).—This manual on cacao culture includes data on the diseases and insect pests and their control.

**El cultivo del cacao y sus proyecciones económicas en el oriente de Caldas [Cacao culture and its economic promotion in the east of Caldas], G. HENAO LONDOÑO** (*Rev. Agropec. [Colombia]*, 6 (1941), No. 26, pp. 55, figs. 8).—This is a general conspectus on cacao, its geographical distribution, varieties, soil and climatic relations, culture in all its phases, and diseases and pests and their control.

**Natural pollination of cocoa, *Theobroma leiocarpa*, on the Gold Coast,** A. F. POSNETTE (*Trop. Agr. [Trinidad]*, 19 (1942), No. 1, pp. 12-16).—That insects are the important pollinating agents for cacao in the Gold Coast plantations was indicated in 3 years' experiments. In periods of profuse bloom only about 10 percent of the flowers were pollinated, while in periods of limited bloom the percentage reached 79. The relative number of available insects appeared to be the controlling factor. By means of cages and banding, it was ascertained that only one of the five species of ants present was capable of pollinizing cacao flowers. Apparently flying insects were responsible for a large part of natural pollination. By covering blooms for different parts of the day, it was established that the active pollinator does not fly at night.

**Fertilizer experiments in an orange grove in the eastern Everglades,** J. R. NEETLES and W. L. FORSEE, JR. (Fla. Expt. Sta.). (*Citrus Indus.*, 22 (1941), No. 12, pp. 6-7).—In experiments with Lue Gim Gong oranges growing near Fort Lauderdale on a fibrous peat soil underlaid with porous marl rock, a benefit from phosphorus was found in the form of increased yields and in improved characteristics of the fruit. The oranges from the no-phosphate plats were softer and more acid when picked and the rinds were measurably thicker than in fruit of phosphated trees. A tendency was noted also for greater dropping of fruit from the nonphosphated trees. The largest-sized fruits were obtained from the high-potassium plats. Certain deficiencies, such as zinc, manganese, and copper, were observed and corrected during the experiment.

**The starch cycle in the Hachiya persimmon,** C. J. ARCHER. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 187-190, figs. 2).—A study of the starch cycle in bearing and nonbearing trees from November 1938 to May 1940 revealed that the normal cycle is similar to that occurring in other deciduous trees. No definite wavelike accumulations and disappearances of starch were observed between the three ages of branches analyzed or within the tissues of the same age branches. The normal starch cycle reflected general growth activities in the tree except during the rapid decrease to the winter minimum. Fruiting suppressed starch accumulation, and evidence was obtained that fruit development is probably cyclic rather than uniform.

**Compilation of data on nut weight and kernel percentage of black walnut selections,** L. V. KLINE and S. B. CHASE (*Amer. Soc. Hort. Sci. Proc.*, 38 (1941), pp. 166-174).—Information is presented, largely in tabular form, on 335 samples representing a total of 212 selections.

**Tung tree investigations,** C. DORMAN (*Miss. Farm Res. [Mississippi Sta.]*, 4 (1941), No. 12, p. 6).—Information is presented on the results of training and pruning studies with tung trees at the South Mississippi Substation and on fertilizer, propagation, and pruning studies with tung trees at the Tung Experimental Field.

**China tung oil and its future,** C. C. CHANG (*China Veg. Oil Corp. Leaflet* 8 [1940], pp. [51]+129, pl. 1, figs. 24).—The status of tung oil production in China is discussed with reference to culture, handling of the product, trade, competition from abroad, competing oils and synthetic substances, etc.

**Cinchona cultivation and the production of totaquina in the Philippines,** J. MABAÑON and H. H. BARTLETT (*Univ. Philippines, Nat. and Appl. Sci. Bul.*, 8 (1941), No. 2, pp. 111-142, pls. 23).—The history of *Cinchona* culture and totaquina production in the Philippines is presented, and an account of experimental studies is given, including plantings of five species. Detailed instructions on planting methods found successful are given, and some important disease problems are discussed. Studies of the therapeutic efficacy of Philippine totaquina are

said to have shown that it compares favorably with quinine, and no untoward effects have been observed.

**Lily culture**, L. H. McDANIELS ET AL. (*Amer. Hort. Soc., Lily Bul.*, 1941, pp. 23, figs. 5).—Information is presented on propagation, culture, winter protection, control of virus and other diseases, resistance to cold, uses, etc.

**Maintenance of shade and ornamental trees**, P. P. FIBONE (*New York: Oxford Univ. Press*, [1941], pp. XVII+422, figs. [175]).—Prepared by a plant pathologist of the New Jersey Experiment Station, this book presents information on the normal growth of trees, planting, fertilization, pruning, treatment of wounds, species and their utilization, control of insects and pests, prevention and treatment of nonparasitic injuries, and the specific pests of various trees.

## FORESTRY

**Forest activities under the impact of war** (*U. S. Dept. Agr., Sec. Agr. Rpt.*, 1941, pp. 205-209).—Information is presented on the lumber and pulpwood demands resulting from war needs; the work of the Forest Service and cooperating agencies in the establishment of shelterbelts, in aiding farmers in improvement of their woodlands, and in protecting forests from fire; the work of the Forest Products Laboratory on wood and wood products utilization; forest conservation activities; the extension of the public forests; etc.

**Twenty years of forest research in the lower South, 1921-1941**, E. L. DEMMON. (*U. S. D. A.*). (*Jour. Forestry*, 40 (1942), No. 1, pp. 33-36).—This is a brief review of the progress of forestry in the two decades since the establishment of the Southern Forest Experiment Station on July 1, 1921, supplemented with a preview of the immediate future.

**Report on experimental planting, Syracuse Forest Experiment Station**, R. P. PRICHARD (*N. Y. State Col. Forestry, Syracuse Univ., Bul.*, 14 (1941), No. 3-c, pp. 43, figs. 9).—Data are presented on the growth rates and behavior of various species and combinations of species established in the experimental forest located within the limits of the city of Syracuse.

**Comparative anatomy and varying physical properties of trunk, branch, and root wood in certain Northeastern trees**, A. C. FEGEL (*N. Y. State Col. Forestry, Syracuse Univ., Bul.*, 14 (1941), No. 2-b, pp. 20).—Observations on a total of 20 species growing on various sites in the Adirondack region revealed that wood of the highest and lowest specific gravity occurred in branches and roots, respectively. Shrinkage in drying was greatest in the branch and least in the root wood. The branches grew more slowly than the roots, and the trunks showed the most rapid development. Branch wood was stronger in compression perpendicular to the grain than was either trunk or root wood, and material from the roots was much weaker. The branches were strongest in compression parallel to the grain when green, and the roots weakest. Root wood was inferior in both the green and air-dry states. Trunk wood was superior to both root and branch wood in stiffness and bending strength. Information is presented on fibers, tracheids, resin canals, wood rays, etc.

**Some effects of incomplete girdling of northern hardwoods**, M. WESTVELD. (*U. S. D. A.*). (*Jour. Forestry*, 40 (1942), No. 1, pp. 42-44).—Of 118 trees girdled in 1929 on experimental plats in the White Mountain National Forest, 36 percent developed bridges of varying widths. A number of the bridged trees died later, so that by 1940 there was only 24 percent of living trees. The method of girdling was a factor in the tree's response. The lowest initial success was attained under the notching system, whereby two-thirds of the trees developed bridges. However, in 1940 there were 35, 33, and 12 percent of surviving trees

under the hacking, notching, and peeling methods, respectively. Of the four species—yellow birch, beech, red maple, and sugar maple—which developed bridges, the heaviest early mortality occurred in the yellow birch. None of the bridged sugar maples died following girdling, and this species was outstanding in its capacity to develop new callus growth.

**Response of American elm to loose and briquette fertilization in the greenhouse.** J. K. MELVIN and A. L. McCOMB. (Iowa Expt. Sta.). (*Jour. Forestry*, 40 (1942) No. 1, pp. 49-51, fig. 1).—Eight fertilizer treatments, four with loose- and four with briquette-type materials, were tested on seedling American elms growing in boxes in the greenhouse in an acid infertile clay subsoil of the Lindley series. Records taken at the end of 5 mo. showed the greatest development in the trees receiving loose superphosphate and sulfate of ammonia. The average total height of this lot was 19.08 in. as compared with 6.02 in. for the next best treatment, that of loose superphosphate alone. No response was obtained with rock phosphate or ammonium sulfate used alone in loose form. None of the briquette treatments were effective, due apparently to the failure of the roots to reach the briquettes. Phosphorus was the most limiting element, and nitrogen became effective once the phosphorus requirements were satisfied.

**Pruning southern pines.** W. R. MATTOON (*U. S. Dept. Agr., Farmers' Bul.* 1892 (1942), pp. [2]+34, figs. 25).—The principles and practices of pruning pine trees are discussed, with special reference to the benefits of pruning, tools and their use, methods of pruning, selection of trees, costs, etc.

**Early effects of pruning in a young shortleaf pine planting.** W. H. CUMMINGS. (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 1, pp. 61-62).—Four yr. after setting in plantation form, shortleaf pines were pruned of all side branches up to one-half their height. Measurements in the next 2 yr. showed that diameter growth at 1.5 and 4.5 ft. was decreased markedly by pruning. Height growth and diameter at 7.5 ft. were not significantly affected. Lower values for taper at 4.5 ft. indicated that pruning favored the development toward a more cylindrical form of the basal section of the stem.

**Unmerchantability in second cut ponderosa pine.** W. L. CHAPEL. (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 1, pp. 45-48, fig. 1).—During the second cutting in 1939 in an experimental area in the Fort Valley Experimental Forest, Ariz., logged originally in 1909, careful records were taken on the volume of defective and unmerchantable logs and of the factors responsible for unmerchantability. There was 10.8 percent of unmerchantable logs, a figure much lower than commonly found in first cuttings. Unmerchantability increased directly with the age and diameter of a tree and its decline in vigor. Since unmerchantability does not become serious until a tree reaches the classes of greatest age (class 4), and poorest vigor (class D), the author suggests the desirability of technical rotations for the various products harvested from ponderosa pine before the trees reach these classes and before any decline in periodic increment occurs.

**Studies on the relation of growth rate to wood quality in *Populus* hybrids.** L. P. V. JOHNSON (*Canad. Jour. Res.*, 20 (1942), No. 1, Sect. C, pp. 28-40).—Experiments were conducted on the relation of growth rate to wood quality in a series of 43 hybrid and parental trees, which involved *P. alba*, *P. grandidentata*, and *P. tremuloides*. Fibers in fast growth annual rings were longer on the average than those in slow growth rings from the same tree. In single annual rings, fibers of early wood were shorter and thicker than those of late wood. Average fiber diameter of individual trees was significantly correlated in a positive manner with growth rate, but the correlation between fiber length and growth rate was well below the level of significance. Short, thick habit of growth was significantly correlated with high density of wood, but correlations between

growth rate (in terms of annual increment in volume) and wood density were insignificant. Pulp and paper tests did not reveal any very striking differences in quality between fast-growing hybrid and slow-growing parental trees, although there remains some doubt as to the suitability of abnormally fast-growth hybrid wood for some of the higher grades of soda pulp paper.

**A bisexual cone of white spruce, S. PAULEY.** (Mich. State Col.). (*Jour. Forestry*, 40 (1942), No. 1, pp. 62-63, fig. 1).—A record is presented of the discovery of a single bisexual cone on a *Picea glauca* (= *canadensis*) tree growing on the campus of the Michigan State College.

**Relation of naval stores yields to frequency of chipping, T. A. LEEFELD.** (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 2, pp. 81-92, figs. 5).—A study of the output from three chipping treatments, (1) customary seasonal chipping, (2) moderate year-round practice, and (3) heavy year-round practice, led to the conclusion that frequent chipping has distinct advantages when rapid exploitation and high annual or seasonal production are desired. It was evident that chipping frequencies should not exceed three times a week during the summer nor every other week during the winter. Where long working life of the same faces or trees is considered more important than high production per year, the results pointed to a schedule of semiweekly chipping in summer, weekly chipping in the spring and fall, and semimonthly during the winter. Even in the most conservative work, loss of gum would result if streaks were chipped less frequently than every 2 weeks in summer and every 6 to 8 weeks in winter. If varying intervals between chippings are out of the question, the results indicate the desirability of weekly chipping from March to November and every other week during the winter, or, for longer working life, a rigid schedule of chipping every other week throughout the year.

**Rubber program makes headway (U. S. Dept. Agr., Sec. Agr. Rpt., 1941, pp. 215-217).**—Information is presented on the progress of the cooperative Latin-American rubber program, the development of synthetic rubber, and the utilization of guayule as a source of rubber.

**An inexpensive planimeter, L. M. DICKERSON.** (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 1, pp. 19-22, figs. 3).—The construction and operation are discussed.

**Circular slide rules for solving linear equations, J. H. BUELL.** (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 1, pp. 26-32, figs. 4).—This article discusses the advantages of the circular rule for field use and gives a detailed example of the construction of such a rule.

**Michigan log marks, edited by C. ALLEN** (*Michigan Sta. Mem.* 4 (1941), pp. [1]+89, figs. 937).—A brief narrative account, compiled by the Works Progress Administration, is presented of the logging of the Michigan virgin white pine forests, together with a description of the marks used for distinguishing the logs of different operators and owners.

## DISEASES OF PLANTS

[Phytopathological research by the Bureau of Plant Industry] (*U. S. Dept. Agr., Bur. Plant Indus. Rpt.*, 1941, pp. 5, 15, 16-18, 19, 24, 25-26, 32-33, 34-35).—Brief reports of progress (*E. S. R.*, 84, p. 768) are given on some of the more important recent findings of the Bureau, including data on a new disease, charcoal rot (*Sclerotium bataticola*), which is taking a heavy toll of the sorghum crop; seed treatment found for controlling head smut and stripe smut of various grasses; necessity for prompt use of chemicals in control of stain fungi in lumber indicated; predictions of white pine blister rust spread in California; causes

of decay in western hemlock; a graft-transmissible mosaic disease of American elm; control of pecan scab; spot fumigation proved effective against root knot; nematodes shown to spread insects and plant diseases in soil; hot-water and formalin treatment of narcissus bulbs found effective against bulb or stem nematode; black blighting and yellow stunting of the Pacific Northwest sugar-beet-seed crop found due to B and S deficiencies, respectively; a tobacco injury proved due to B deficiency, a black-root-rot resistant high quality Burley tobacco developed by selection, and downy mildew controlled by high temperatures; sugar-cane chlorotic streak disease found spreading in Louisiana; and a summary of the work in identifying and collecting fungi and in the plant-disease survey.

**Diseases of plants in the United States in 1939**, N. W. NANCE (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 1941, Sup. 128, pp. 209-378, figs. 21*).—This twenty-third annual report on the incidence of plant diseases in the United States follows the usual plan (*E. S. R.*, 84, p. 59) in presenting weather data before taking up the diseases of individual crop plants.

**Recent developments in plant diseases in the United States**, N. E. and R. B. STEVENS. (*Univ. Ill. et al.*). (*Bot. Rev.*, 7 (1941), No. 12, pp. 714-736, figs. 11).—The present summary of information on certain diseases in the United States through the season of 1940 (29 references), largely a continuation of one previously noted (*E. S. R.*, 77, p. 793), includes the Dutch elm disease, wasting disease of eelgrass, X-disease of peach, tobacco downy mildew, bacterial wilt of corn, bunt, *Cercospora* foot rot, stem rust, and leaf rust of wheat, bean rust, and late blight and bacterial ring rot of potato.

**The Plant Disease Reporter**, [January 15 and February 1 and 15, 1942] (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 26 (1942), Nos. 1, pp. 1-31, figs. 2; 2, pp. 31-56; 3, pp. 57-82, figs. 2).—In addition to the host-parasite check-list revision, by F. Weiss (Nos. 1 and 2, *Prunus*, and No. 3, *Pseudolaria to Pyrus*), the following items are noted:

No. 1.—The weather and plant disease situation in Massachusetts for 1941, by O. C. Boyd; fruit diseases in Idaho in 1941, by E. C. Blodgett; diseases of fruits and vegetables on the New York market during the months of January to August, inclusive, 1941, by C. O. Bratley and J. S. Wiant; grass disease in Wisconsin in 1941, by J. L. Allison and D. W. Chamberlain; and crown gall on the weed *Malva rotundifolia*, by E. M. Hildebrand and L. M. Massey.

No. 2.—The use of Spergon for sweetpotato seed and sprout treatments, by O. H. Elmer; observations on some diseases of tomatoes and other vegetables in south Texas, including a new tomato disease of unknown cause considered distinct from bunchy top and involving an internal necrosis, for which the name "rosette" is proposed, by A. L. Harrison and S. S. Ivanoff; occurrence of tomato leaf mold (*Cladosporium fulvum*) and of muskmelon powdery mildew (*Erysiphe cichoracearum*) in the field in New Hampshire, by R. W. Barratt; downy mildew (*Peronospora manshurica*) on soybean seeds, by H. W. Johnson and C. L. Lefebvre; charcoal rot (*Rhizoctonia bataticola*) of corn and sorghum in Nebraska, by J. E. Livingston; some observations on tobacco diseases in Virginia in 1941, by S. B. Fenne; and spread of white pine blister rust in southern Appalachian States in 1941, by R. G. Pierce.

No. 3.—Grass diseases in Michigan in 1941, with host and pathogen indexes, by J. R. Hardison; brief notes on *Phyllachora fusticarpa* in Florida, and destructive occurrence of *Diplodia natalensis* on okra stalks in Alabama; spread of white pine blister rust during 1941; and new blister rust infections for 1941.

[Phytopathological studies by the Georgia Station]. (Partly coop. U. S. D. A. et al.). (*Georgia Sta. Rpt.*, 1941, pp. 25-28, 102, 105-107, fig. 1).—Brief reports are given on the reaction of cotton varieties to cotton wilt and root

knot; muscadine grape diseases, including a black rot differing from that of bunch grapes, and *Cercospora brachypus* (a *Mycosphaerella*) leaf disease by Jenkins (E. S. R., 86, p. 648); pepper resistance to *Sclerotium rolfsii*; peanut leaf spot control; control of tomato *Macrosporium* blight and stem canker; water-melon breeding for *Fusarium* wilt resistance; selection of snap beans (also bunch or runner type) for resistance to root rots, nematodes, ashy stem blight, and southern blight (*S. rolfsii*); and diseases of Austrian winter peas, English garden peas, vetches, and lupines, with special reference to breeding and selection for resistance.

**Plant pathology**, G. M. REED (*Brooklyn Bot. Gard. Rec.*, 30 (1941), No. 2, pp. 81-85).—Brief reports are included on research for 1940 on the inheritance of resistance of oats hybrids to loose and covered smuts and physiologic races (including the experimentally produced) of these smuts, and sorghum smut, including the effect of endosperm removal, presoaking of seeds, and water extracts of seeds on infection, smut in relation to sorghum hybrids, and comparison of infection results in greenhouse v. field.

**Report of the plant pathologist**, L. N. H. LARTER (*Jamaica Dept. Sci. and Agr., Ann. Rpt.*, 1941, pp. 13-14).—Brief notes are presented on diseases reported and investigated during the year beginning April 1940, with special emphasis on those of banana, coconut, pimento, mango, potato, peanut, and cassava.

**New and interesting plant diseases**, W. C. MOORE (*Brit. Mycol. Soc. Trans.*, 25 (1941), pt. 2, pp. 206-210, pl. 1).—The following are presented: A leaf blotch of *Cypripedium* caused by *Penicillium thomii*, leaf spot of *Primula*, and leaf spot of *Helium* (*Septoria helonii*).

**Leaf spot diseases of lettuce and Antirrhinum**, T. E. T. BOND (*Trop. Agr. [Ceylon]*, 97 (1941), No. 2, pp. 62-67, pls. 2).—An account is given of two leaf spots new to Ceylon, viz, one of lettuce associated with *Septoria lactucae* and one of *A. majus* associated with *Phyllosticta antirrhini*.

**Frost killing and hardiness of plants: A critical review**, J. LEVITT (*Minneapolis, Minn.: Burgess Pub. Co.*, [1941], pp. [1]+V+211).—"Winter injury" takes a tremendous toll of plant life in all but tropical climates. There are many more or less distinct factors responsible for the injury, but it is now believed evident that by far the most destructive is the actual freezing of the plant and that an understanding of the cause and prevention of frost injury would to all practical purposes solve the winter injury problem. In this monographic review (25 pages of references) only those factors are considered which appear (or at one time have appeared) capable of shedding some light on the causes of frost injury and the mechanisms adopted by plants to prevent it. The subject matter is considered under the three main topics of frost killing, frost hardiness, and current theories on the causes of injury and resistance.

**On the physiological basis of inherited disease resistance**, J. W. GOWEN. (Iowa State Col.). (*Genet. Soc. Amer. Rec.*, 10 (1941), p. 145).—An abstract.

**New species of Tennessee fungi**, J. DEARNESS (*Mycologia*, 53 (1941), No. 4, pp. 360-366).—New species are described as occurring on living leaves of various hosts, under the genera *Phyllosticta*, *Phlyctaena*, *Septoria*, *Leptothyrium*, *Leptostromella*, *Gloeosporium*, and *Cercospora*, and *Briosis azaleae* n. comb., *Dothiorella mali fructus* n. var., and *Coryneum rhododendri fusoides* n. var.

**Micromicetos nuevos para la flora Argentina [Fungi new to the Argentine flora]**, J. C. LINDQUIST (*Darwiniana*, 5 (1941), pp. 240-247).—Twenty-one species are briefly considered, for the most part plant-parasitic forms.

**A method for characterizing smut fungi exemplified by some British species**, G. C. AINSWORTH (*Brit. Mycol. Soc. Trans.*, 25 (1941), pt. 2, pp. 141-147).—"A method is described by which the principal characters of a smut

fungus can be summarized by a formula comprised of 12 numerals. The method is illustrated by formulae for the commoner British smuts."

**Data on the cultural characteristics of a species of *Coprinus*, G. T. JOHNSON and A. C. JONES** (*Mycologia*, 33 (1941), No. 4, pp. 424-433).—The fungus studied was closely related to or identical with *C. cubensis*.

**Notes on *Coprinus micaceus* growing in an unusual habitat, S. M. PADY** (*Mycologia*, 33 (1941), No. 4, pp. 411-414).—The fungus was found growing and fruiting on oak flooring, with associated rotting of the wood.

**Descriptions of the South African Pythiaceae with records of their occurrence, V. A. WAGER** (*Bothalia*, 4 (1941), No. 1, pp. 3-35, figs. 18).—*Pythium* (10 species) and *Phytophthora* (7 species) are included. An annotated host index and 30 references are appended.

**Water moulds as a source of infection by pathogenic species of *Phytophthora*, E. M. BLACKWELL and G. M. WATERHOUSE** (*Mycologia*, 33 (1941), No. 4, p. 449).—A note suggesting that "as parasitic species of *Phytophthora* can lead a saprophytic existence in the soil, so they may abide saprophytically in water."

**On the history and diagnosis of *Polyporus tomentosus* Fries, *Polyporus circinatus* Fries, and *Polyporus dualis* Peck, W. R. HADDOW** (*Brit. Mycol. Soc. Trans.*, 25 (1941), pt. 2, pp. 179-190, pl. 1).

**Las especies de *Septobasidium* en la Argentina, J. B. MARCHIONATTO** (*Darwiniana*, 5 (1941), pp. 248-263, pls. 4, figs. 3; *Eng. abs.*, p. 263).—Ten species and one variety of this fungus genus are described.

**Some lethal effects of ultra-violet radiation on fungus spores, A. DIMOND and B. M. DUGGAR** (Univ. Wis.). (*Natl. Acad. Sci. Proc.* 27 (1941), No. 10, pp. 459-468, figs. 3).—Testing spores of *Rhizopus sinuatus*, *Mucor dispersus*, and *Aspergillus melleus* with respect to their resistance to ultraviolet radiation of 2,650 a. u. wavelength, sigmoid survival curves were obtained for the first and for the minus strain of the second fungus from 4-day cultures, whereas curves describing a logarithmic order of death were exhibited by *A. melleus* spores from similar cultures. The three fungi showed marked differences in susceptibility to this irradiation, which may possibly be accounted for by a combination of the differences in pigmentation, spore size, and number of nuclei. A trend of increasing resistance to irradiation with increased age was observed for *R. sinuatus* spores.

**Tenacity of protective fungicides, J. W. HEUBERGER** (Conn. [New Haven] Expt. Sta.). (*Chron. Bot.*, 7 (1942), No. 1, pp. 9-10).—The author discusses inherent, added, and reduced tenacity; methods of determining and evaluating tenacity of protective fungicides in the laboratory; tenacity of some copper compounds; comparison of laboratory and field data on tenacity; and tenacity of new materials.

**Vergleichende Untersuchungen über den mikrobiciden Effekt verschiedener Konservierungsmittel [Comparative investigations of the bactericidal action of various preservative substances], H. LAGONI** (*Zentbl. Bakt. [etc.]*, 2. Abt., 103 (1941), No. 12-14, pp. 225-231, fig. 1).—Assay of the growth-inhibitory effects under laboratory conditions indicated that diacetyl possesses almost as strong a bactericidal action as benzoic acid, whereas sodium benzoate does not.

**Attenuation of bacteria pathogenic on plants, A. J. RIKER** (Univ. Wis.). (*Chron. Bot.*, 6 (1941), No. 17-18, pp. 392-393).—A brief review of work by the author and others.

**Microbial activity as influenced by root excretions, M. I. TIMONIN** (*Chron. Bot.*, 6 (1941), No. 19-20, p. 440).—Continuing work previously noted (*E. S. R.*, 85, p. 69), results so far obtained apparently indicate that the *Fusarium*-resistant

flax variety used excretes or diffuses HCN through its roots in sufficient amounts to influence various groups of micro-organisms differently.

Here's a microbe that needs no pampering, W. W. UMBRETT and K. G. VOGLER (*Wisconsin Sta. Bul.* 453 (1941), pp. 62-63).—This is a brief report of studies on metabolism of the sulfur bacterium *Thiobacillus thiooxidans* and the mechanism by which it acts on S to control common potato scab. The fact that it is the most acid-resistant of known micro-organisms also offers hope that it may prove useful to the fermentation industries.

X-ray and crystallographic studies of plant virus preparations.—I, Introduction and preparation of specimens. II, Modes of aggregation of the virus particles. III, The structure of particles; biological implications, J. D. BERNAL and I. FANKUCHEN (*Jour. Gen. Physiol.*, 25 (1941), No. 1, pp. 111-165, pls. 4, figs. 18).—These papers give an account of studies of plant virus substances isolated by F. C. Bawden and N. W. Pirie and examined by special X-ray apparatus and cameras developed for the purpose. Two modes of aggregation were observed, viz, a disoriented sol at low concentrations and an oriented sol passing continuously over to an oriented gel at higher concentrations. Solutions of medium strength divide into two layers on standing. X-ray examination indicated the particles to be equidistant and the sol to be a new kind of liquid crystal with a regular hexagonal arrangement in cross section. The aggregation phenomena are discussed in great detail. The original "crystals" observed by Stanley (E. S. R., 73, p. 800; 77, p. 205) are shown to be gels of the type here studied in the form of elongated tactoids. In these gels the particle arrangement in cross section is so perfect that each specimen is a two-dimensional single crystal. It is concluded that the virus preparations consisted of approximately cylindrical particles about 150 a. u. in diameter. The forces maintaining the particles equidistant in these gels are probably due to the ionic atmospheres surrounding them. Further consideration of the results leads to an explanation for the other colloid phenomena shown by the viruses, particularly the formation of tactoids and gels. The spindle shape of the tactoids is shown to be due to anisotropic surface tension caused by the parallel arrangement of the long particles on the surface. Dilute gels appear to be composed of tactoids of a multiply branched character showing thixotropic behavior. This theory may have wide extensions to other colloid systems.

Even in solution the particles were found to have an inner regularity like that of a crystal, but closer analysis revealed that the X-ray patterns are not directly comparable to those of a crystal. Contrary to earlier observations, the particle seems to be virtually unchanged on drying and must therefore contain but little water. There are marked resemblances with the structure of both crystalline and fibrous protein, but the virus structure does not belong to any of the classes hitherto studied. Comparisons of the optical and X-ray examinations are discussed for viruses of three strains of tobacco mosaic, two of cucumber mosaic, two of potato X, and one of tomato bushy stunt. In the last case, measurement confirmed the deduction from its cubic crystal habit that it was composed of spherical rather than long particles. This single example is sufficient to show that the elongated particle form which gives rise to all the anomalous physical properties of the other viruses studied is of no essential biological importance. The similarity and differences observed between the physical properties of these preparations run closely parallel to their clinical and serological classification. The biological implications of the results of the study are discussed, together with possible applications of the new methods of examination to the study of colloid and biological problems.

Some notes on the relationship of plant viruses with vector and non-vector insects, K. M. SMITH (*Parasitology*, 33 (1941), No. 1, pp. 110-116, pls. 2).—"Extracts of caterpillars and other insects are shown to inhibit the infective power of tobacco mosaic and tobacco necrosis viruses. The inhibitor is not sedimented after spinning for 2.5 hr. at 30,000 r. p. m. Experiments with nonvector insects such as caterpillars have shown that the virus of sugar beet curly top, of tobacco ring spot, and other viruses are destroyed within the body of the insect. On the other hand, tobacco mosaic virus passes through the body of the caterpillar unchanged though greatly reduced in concentration. By the use of the specific insect vector and artificial feeding methods it was possible to recover the virus of curly top 24 hr. after it had been injected into the blood of the caterpillar, but the viruses of tobacco mosaic and tobacco necrosis could not be so recovered. Experimental evidence is given to show that the virus of beet curly top is present in the saliva of viruliferous insects."

A virus disease of *Emilia scabra*, C. A. LOOS (*Trop. Agr. [Ceylon]*, 97 (1941), No. 1, pp. 18-21, pl. 1).—"The principal symptom of this virus disease, first observed in 1940, is a yellow vein banding. It was successfully transmitted by grafting and differs from the spotted wilt on this weed host."

The cytoplasmic and nuclear inclusions associated with severe etch virus, F. M. L. SHEFFIELD (*Jour. Roy. Micros. Soc.*, 61 (1941), No. 1-2, pp. 30-45, pls. 3).—"The author describes further properties than those noted by Kassanis (E. S. R., 83, p. 205) of the two kinds of inclusions induced by this virus: (1) The cytoplasmic inclusions are amorphous, consisting chemically of mixtures of proteins with fats and lipoids. They are formed by the aggregation of particles which appear in the streaming cytoplasm, and may contain some birefringent particles and give rise to small needlelike bodies. They can be pricked or divided into portions with a microneedle. They contain the virus, which is also present in other parts of the cell. They are numerous and occur in most tissues of the plant. (2) The intranuclear inclusions give protein reactions and are more stable. They take the form of thin rectangular plates, and as many as 30 may be found in a single nucleus. They can be isolated, but can be broken or dissolved only with difficulty. Almost every nucleus contains them and they have been found in almost all tissues. They occur in the seed but have not been found in the young embryo. The virus is not transmitted by the seed. These two types of inclusions are briefly discussed and compared with other inclusions occurring in diseased and normal tissues."

A blotch and char-spot of western grasses, R. SPRAGUE. (Oreg. Expt. Sta. coop. U. S. D. A. and N. Dak. Sta.). (*Northwest Sci.*, 15 (1941), No. 4, pp. 81-85, fig. 1).—"The tawny leaf blotch of some Pacific coast grasses and the charcoal or char spot of some western grasses (hosts and collections listed) are due to *Septogloeum oxysporum*, which produces stromata bearing pycnidia and perithecia. It is expected that the fungus will eventually be assigned to a *Dothidella*-like genus, and it is related to if not identical with the species known sometimes as *D. aristidae*."

*Stagonospora arenaria* on grasses, R. SPRAGUE. (Oreg. Expt. Sta. coop. U. S. D. A.). (*Mycologia*, 33 (1941), No. 4, pp. 371-379, figs. 2).—"S. *arenaria* causes a purple leaf blotch of a number of grasses in the north temperate and subarctic regions of the Northern Hemisphere. An emended description of the species is presented."

Turf injuries in Minnesota, I. W. TERVET (*Abstr. in Minnesota Sta. Rpt.* 1941, p. 46).—"Snow mold of bent and other turf grasses was severe in the spring of 1941. Some of this injury was due to a fungus—*Typhula itoana*—that had not been recognized in Minnesota as associated with this disease. An unusual de-

velopment of fruiting bodies of this fungus occurred on one bentgrass area in November 1940 and severe snow mold occurred in April 1941 on the grass which had previously borne sporophores. A second type of injury resulting in the death of extensive areas of bent and bluegrass occurred in the 2 weeks following the disappearance of the snow. This injury apparently resulted from exposure of the waterlogged turf to sunlight and strong wind resulting in a scorching of the leaf blades and finally death to the plant."

**Physiological studies of the fungus *Ophiobolus graminis* Sacc.—I, Growth factor requirements, N. H. WHITE** (*Jour. Council Sci. and Indus. Res. [Austral.], 14 (1941), No. 2, pp. 137-146, figs. 2*).—"O. *graminis* requires the growth factors biotin and thiamin for mycelial development. Growth occurs only when biotin is present, but more than double the amount of growth follows the addition of thiamin. Either of the growth factors can be a limiting factor when present in suboptimal amounts. For optimal growth conditions, O. *graminis* requires about 0.1 mg. of solid biotin (2.0 vitamin H units) and 0.1 mg. of solid thiamin (30.0 vitamin B<sub>1</sub> units) per 100 ml. of solution. Growth factors are present in optimal amounts in extracts of wheat roots, wheat straw, and in 0.5 percent peptone. Soil extracts are deficient in both the growth factors, and 0.05 percent 'Marmite' solution contains a suboptimal amount of biotin. Growth of the fungus is limited by the interaction of three sets of factors—biotin, then thiamin, and then a nutritional factor present in wheat straw, wheat roots, peptone, and asparagine. The growth factor requirements of the fungus are discussed in relation to certain aspects of its parasitism."

**Alkaloids from *Zephyranthes texana*, *Cooperia pedunculata*, and other Amaryllidaceae and their toxicity to *Phymatotrichum omnivorum*, G. A. GREATHOUSE and N. E. RIGLER** (*Tex. Expt. Sta. coop. U. S. D. A.*). (*Amer. Jour. Bot.*, 28 (1941), No. 8, pp. 702-704).—Lycorine was shown to occur in the bulb and root tissues of *Z. texana* and *C. pedunculata* at about 0.02 and 0.04-0.05 percent of the fresh weight, respectively. A second alkaloid, presumed to be  $\psi$ -lycorine, was isolated from the mother liquors of *C. pedunculata* at about 0.002 percent concentration. Other members of the Amaryllidaceae were subjected to histochemical tests for alkaloids. Studies of the toxicity, quantity, and localization of the alkaloids in members of this plant family suggested that their presence may contribute to the immunity of this group to *P. omnivorum* root rot.

**La desinfestación de la semilla de algodónero y otros factores relacionados con su poder germinativo [The disinfection of cottonseeds and other factors in their germinability], M. A. DI FONZO** (*Argentina Min. Agr., Junta Nac. Algodón [Pub.] No. 53 (1941), pp. 15*).

**Ergot of Paspalum in Queensland, R. F. LANGDON** (*Austral. Jour. Sci.*, 3 (1941), No. 6, pp. 169-170).—This is a note on the history of ergot of *Paspalum* spp. in Queensland and of the probable species of *Claviceps* concerned. Observations of 1940 suggested the existence of physiologic races of *C. paspali*, and the recent epidemic may have followed the production of a new and more virulent race.

**Untersuchungen über die Genetik und Physiologie der Resistenz der Kartoffel gegen *Phytophthora infestans* de Bary [Studies of the genetics and physiology of the resistance of potatoes to *P. infestans*], H. LEHMANN** (*Züchter*, 13 (1941), No. 2, pp. 33-34, fig. 1).—Resistance to late blight in the 72-chromosome *Solanum demissum* appeared to behave as a simple mendelian dominant. The mode of inheritance of resistance was the same for the two fungus races used.

**La podredumbre anular o marchitez bacteriana de las papas [Bacterial ring rot of potatoes], D. A. TEXERA and A. S. MÜLLER** (*Agr. Venez.*, 5 (1941),

No. 57-58, pp. 27-30, figs. 2).—A brief general account of the disease due to *Phytophthora sepedonica* in Venezuela.

Untersuchungen über die "Sang"-Krankheit der Kartoffeln im Rheingau [Investigations of the "sang" disease of potatoes in the Rheingau], G. GLÖCKNER (*Angew. Bot.*, 22 (1940), No. 3, pp. 201-252, figs. 13).—In the northern part of Rheingau there has appeared for several years a wilt disease known locally as "sang," which annually makes inroads varying from reduced yields to total loss of the crop. The disease is first observed when prolonged rains are followed suddenly by several days of hot, dry weather, there being a rolling of the upper leaves, followed by a yellowing of the whole plant, progressive rolling and wilting of the leaves from above downward, drooping of the leaf stalks and shoots, and final death of the plant starting from the leaf tips. Microscopical examination of the infected stems revealed the presence of *Verticillium albo-atrum*. The author discusses the relations of soil, climate, culture, and fertilization to the disease, varietal reactions, and control experiments and recommendations, and compares similar diseases in other regions. There are 33 references.

Versuche zur Schaffung einer einfachen Methode für die Prüfung des Verhaltens verschiedener Kartoffelsorten gegen Schorf [Attempts to develop a simple method of testing the reactions of different potato varieties to common scab], W. MICHEL (*Angew. Bot.*, 22 (1940), No. 2, pp. 133-146).—From the experiments outlined, the author believes he has shown a correlation of the amount of tuber transpiration by a potato variety with its reaction to *Actinomyces scabies* and that this relation offers a basis for developing a practical test for scab resistance. The preliminary results are presented because of lack of assurance that the studies could be continued.

Effect of sulfur and limestone soil treatments on potato scab in a sandy soil, A. H. EDDINS. (Fla. Expt. Sta.). (*Amer. Potato Jour.*, 18 (1941), No. 11, pp. 312-316).—In 4-yr. tests in Florida, scab was reduced in infested Leon fine sand (original pH 5.3-6.2), prairie phase, by S treatment, but the pH reactions established proved unsuitable for the best growth of potatoes. The disease was also reduced but not eliminated from the first crop grown in soil which had been treated with both S and limestone between potato crops. Neither treatment appeared very practical. In the latter case the disease increased the second year, being then almost as severe on potatoes grown in the treated as in the nontreated land.

Obtaining virus-free potatoes, J. G. BALD and D. O. NORRIS (*Jour. Council Sci. and Indus. Res. [Austral.]*, 14 (1941), No. 3, pp. 187-190).—"Two attempts have been made to obtain potatoes on the variety Up-to-Date (Factor) free from all virus diseases, particularly from virus X, which was reported to be present in every plant of this variety. In the first attempt one tuber free from virus X was obtained, but it was found to carry the virus of leaf roll. At the second attempt tubers were found which appeared to be completely virus-free."

Studies on the nature of rice blast resistance, I-III [trans. title], H. YOSHII (*Bul. Sci. Fakult. Terkult., Kyushu Imp. Univ.; Fukuoka, Jap.*, 9 (1941), No. 3, pp. 277-291, 292-296, 297-307; *Jap. text; Eng. abs.*, pp. 291, 296, 307).—Three papers are presented:

I. *The effect of silicic acid to the resistance.*—The resistance of the leaf blade to rice blast (*Piricularia oryzae*) and the percentage of silica therein were proportional to the amount of silicic acid supplied in the nutrient solution, but the toughness of the blade was not.

II. *The effect of combined use of silicic acid and nitrogenous manure to the toughness of the leaf blade of rice and its resistance to rice blast.*—Adding

silicic acid to the soil increased the plant's resistance to blast. The toughness of the leaves decreased with increase in nitrogenous manure. With equal amounts of the latter, the percentage of silica in the leaves of rice grown in solutions containing silicic acid was higher but their toughness was less than in the absence of added silicic acid. Measurement of the toughness of the leaf blades is considered an effective method of grading rice for resistance to blast, when grown under unfavorable conditions such as surplus of nitrogenous manure.

**III. Relation between rice blast resistance and some physical and chemical properties of the different portions of the leaf blade of rice.**—Measuring the toughness and percentages of silica and N at the tip, middle, and basal portions of the leaf blade, the resistance to needle puncture was greatest towards the base, intermediate at the middle, and least at the tip; the percentage of silica was greater at the tip than at the base, whereas the reverse was true for N. It is concluded that the susceptibility of rice to blast is proportional to the amount of N but inversely so to that of silica in the different parts of the leaf blade, but there is little or no relation between resistance and the toughness of portions of the leaf.

**Sterility of rice panicles**, E. BALDACCI (*Internatl. Bul. Plant Protect. [Roma]*, 15 (1941), No. 6, pp. 114M-116M).—A note on this trouble in Italy and the various factors concerned directly or indirectly in its etiology.

**La mancha blanca del ajonjolí [White spot of sesame]**, A. S. MÜLLER and D. A. TEXERA (*Agr. Venez.*, 5 (1941), No. 57-58, pp. 47-49, figs. 3).—On the disease of leaves and seed capsules due to *Cercospora sesami*.

**Reducing southern Sclerotium rot of sugar beets with nitrogenous fertilizers**, L. D. LEACH and A. E. DAVEY. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 1, pp. 1-18, figs. 4).—Nitrogenous fertilizers in field tests consistently reduced *S. rolfsii* infection in sugar beets, as did also  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{NH}_3$ ,  $\text{Ca}(\text{NO}_3)_2$ , and cyanamide at equivalent amounts of N under favorable conditions. On the average, 50 lb. N per acre reduced infection by about 28 percent, 100 lb. by 54 percent, and 200 lb. by 65 percent. Yields were increased both by disease control and growth stimulation in most fields, but economical use of the method is confined to places where sugar beets respond to N fertilizers. In laboratory trials low concentrations of  $\text{NH}_3$  in aqueous solution were toxic to both mycelia and sclerotia, and  $(\text{NH}_4)_2\text{SO}_4$  was also mildly toxic to mycelia, but  $\text{Ca}(\text{NO}_3)_2$  at similar concentrations proved nontoxic to mycelia and sclerotia. These data suggest that the field control may have been due to factors other than  $\text{NH}_3$  toxicity. Heavy applications of anhydrous ammonia ( $\text{NH}_3$ ) and cyanamide to spontaneously infested soils failed to destroy the sclerotia or to reduce their number. To explain the partial field control obtained, it is suggested that changes in the metabolism of the pathogen may reduce its growth or pathogenicity, that resistance of the host may be increased by alteration of its metabolism and anatomy, or that there may be a suppression of the pathogen because of a change in the balance of micro-organisms in the soil. There are 21 references.

**Results of experiments with chlorotic streak in 1940**, E. V. ABBOTT. (U. S. D. A.). (*Sugar Bul.*, 19 (1941), No. 14, pp. 60-61).—A progress report (E. S. R., 84, p. 207) considering the effect of this virus disease of sugarcane on germination and yields, secondary spread, varietal resistance tests, roguing as a means of control, and its present importance.

**Two sweet potato soft rots and their prevention during storage** (*New Jersey Stas. Plant Disease Notes*, 19 (1941), No. 7, pp. 25-28).—Notes are presented on *Rhizopus* soft rot, said to be one of the most destructive post-harvest diseases of sweetpotatoes. Attempts at control by lowering the storage temperature, however, are likely to lead to other rots, the most common of which

is due to *Mucor racemosus*. It is suggested from the data available that for best results sweetpotatoes be cured for 7-10 days at 80°-90° F. and relative humidity of about 92 percent, and then stored at 50°-55° and humidity of about 80 percent.

The determination of some amino acids in tobacco mosaic virus protein, A. F. ROSS (*Jour. Biol. Chem.*, 138 (1941), No. 2, pp. 741-749).—The virus was found to contain 3.9 percent tyrosine, 4.5 tryptophane, 4.7 proline, 9 arginine, 6.7 phenylalanine, 6.4 serine, and about 5.3 percent threonine. Glycine and histidine appeared to be absent. No differences were noted between the chemically and centrifugally isolated samples.

A quantum yield for the inactivation of tobacco mosaic virus protein, F. M. UBER. (Univ. Mo.). (*Nature [London]*, 147 (1941), No. 3718, p. 148).—The yield value for the virus protein was found to be smaller and, compared to urease, inversely proportional to the molecular weight.

Versuche zur Markierung von Tabakmosaikvirus mit Radiophosphor [Study of radiophosphorus as a tobacco mosaic virus indicator], H. J. BORN, A. LANG, G. SCHRAMM, and K. G. ZIMMER (*Naturwissenschaften*, 29 (1941), No. 14-15, pp. 222-223).

Notas sobre la "yerba sosa" (Orobanche) del tabaco [Notes on *O. ramosa* parasitizing tobacco], S. C. BRUNER (*Rev. Agr. Cuba*, 23 (1940-41), No. 16, pp. 16-20, figs. 2).

Das Tabak-Ringspot-Virus als Erreger einer Gelbfleckigkeit des Kartoffellaubes [Tobacco ring spot virus as the cause of a yellow mottling of potato leaves], E. KÖHLER (*Angew. Bot.*, 22 (1940), No. 6, pp. 385-399, figs. 15).—From yellow mottled potato plants three strains of tobacco ring spot virus were isolated and identified on the bases of cross inoculations, serological reactions, and determination of inactivation temperatures and dilution limits.

A phytopathogenic bacterium fatal to laboratory animals, R. P. ELROD and A. C. BRAUN (*Science*, 94 (1941), No. 2448, pp. 520-521).—In a serological study of the green fluorescent phytopathogenic bacteria, *Phytomonas polycolor* (cause of a tobacco leaf spot) was found to be extremely virulent to small laboratory animals. Though a comparative study has not yet been completed, all available evidence suggests that it is in reality *Pseudomonas aeruginosa*.

The wheat rust problem of India, K. C. MEHTA (*Cur. Sci [India]*, 10 (1941), No. 8, pp. 357-361).—Sources of annual recurrence, dissemination in relation to initial outbreaks, physiologic races, and control methods in India are considered.

Diseases of vegetables, L. OGILVIE ([*Gt. Brit.*] *Min. Agr. and Fisheries Bul.* 123 (1941), pp. IV+84, pls. 4).—This handbook takes up in succession the diseases of some 23 individual vegetable crops and their control and the various types of general control measures (soil and seed treatments, control of damping-off, fungicides, apparatus, and cleansing greenhouses). Indexes of parasites and of nonparasitic and virus diseases are provided.

Market diseases of fruits and vegetables: Asparagus, onions, beans, peas, carrots, celery, and related vegetables, G. B. RAMSEY and J. S. WIANZ (*U. S. Dept. Agr., Misc. Pub.* 440 (1941), pp. 70, pls. 16).—This is the seventh (*U. S. R.*, 82, p. 59) in a series designed to aid in recognizing and identifying economically important pathological conditions of fruits and vegetables in marketing channels, to facilitate inspection and decrease losses. Of the 16 plates, 8 are in color.

Über die Abhängigkeit der Spritzmittelschäden von Temperatur und Jahreslauf [The dependence of spray injury on temperature and season of the year], H. DAXER (*Anz. Schädlingsk.*, 17 (1941), No. 3, pp. 26-35, figs. 6).—Beans were used as test plants. There are 18 references.

**Chocolate spot of beans in 1941**, W. M. WARE and H. H. GLASSCOCK (*Agriculture, Jour. Min. Agr. [Gt. Brit.]*, 48 (1941), No. 2, pp. 91-94).—Notes on this *Botrytis*-induced disease of field beans and broadbeans, with special reference to the 1941 epidemic in Great Britain.

**Spraying and dusting for the control of celery early blight in the Everglades**, G. R. TOWNSEND (*Florida Sta. Bul.* 366 (1942), pp. 26).—Reporting on 11 yr. of experimentation, this period has been marked by a transition from a 5-5-50 bordeaux formula prepared from difficultly soluble granular  $\text{CuSO}_4$  and stone lime to 4-2-50 and 4-4-50 formulas prepared from readily soluble powdered  $\text{CuSO}_4$  and  $\text{Ca(OH)}_2$ . More recently many insoluble Cu compounds have been introduced as bordeaux substitutes. The experiments indicate that better results follow reduction of the Cu:Ca ratio to 2:1. Addition of wettable S to bordeaux reduced the injury by high-Ca bordeaux formulas and improved the control of early blight (*Cercospora apii*). Several plant nutrient materials added to the bordeaux did not seriously interfere with its fungicidal action. Most of the insoluble Cu compounds proved inferior to the bordeaux formulas, and the cuprous oxides and basic copper chloride are the only ones here approved for current use.

**Investigations on the invasion of mushroom beds by *Pseudobalsamia microspora***, H. H. GLASSCOCK and W. M. WARE (*Ann. Appl. Biol.*, 28 (1941), No. 2, pp. 85-90, fig. 1).—It is concluded from the evidence that the fungus is introduced into the beds with the casing soil, and isolation from freshly dug soils further supports this view and indicates that it is a common soil organism. Methods of detecting and culturing the fungus are given. The most practical way of preventing introduction is to avoid contaminated soil, but in some instances early attacks were controlled by removal of the affected part of the bed and treatment of the site with disinfectants. Factors influencing reinfestation are discussed.

**Effect of seed treatment on the stand and yield of peas**, G. L. McNEW. (N. Y. State Expt. Sta.). (*Canner*, 92 (1941), Nos. 6, pp. 56, 58, 60, 62, figs. 2; 7, pp. 16, 18, 20).—This paper, summarizing the results of 15 field experiments with 7 varieties of peas, is not considered as the final word on the use of seed treatments but rather as a progress report. However, the results suggested to the author the following main conclusions: Cuproicide-graphite treatment is very effective and the least expensive of any tested, but may cause slight injury to the plants. The organic mercurials are good seed protectants and would probably be of most service where copper causes injury. New Improved Ceresan is not advised for peas because of injury. Spergon offers such distinct promise for pea seed treatment that, in spite of its present price, canners are advised to test it further in experimental plantings.

**Pepper wilt and control measures in the Province of Mendoza [Argentina]**, J. B. MARCHIONATTO (*Internat. Bul. Plant Protect. [Roma]*, 15 (1941), No. 5, pp. 90M-91M).—*Fusarium vasinfectum* was determined as the cause. When the plants were grown in very broad furrows, the factors favoring development of the disease were reduced to a minimum and considerably fewer plants were attacked.

**Black root disease of white radish** (*New Jersey Stat. Plant Disease Notes*, 19 (1941), No. 4, pp. 13-16).—A number of growers in northern New Jersey have encountered this disease, due to *Aphanomyces raphani*, in recent years, but satisfactory field control measures are still not available. The White Icicle variety has been most susceptible, the Red Globe types have not been seriously injured, and the White Chinese winter radish is reported very resistant. In pot tests chloropicrin gave perfect control, but it remains to be seen whether it can be used successfully under field conditions.

New developments in the control of tomato diseases, A. L. HARRISON. (Tex. Expt. Sta.). (*Contact*, 7 (1941), No. 3, pp. [2-3]).—A note on breeding for disease resistance, development of a wilt-resistant tomato, and spraying and dusting for leaf diseases.

Control of the kromnek (spotted wilt) disease of tomatoes, E. S. MOORE (*Nature* [London], 147 (1941), No. 3729, pp. 480-491).—A note on this virus disease in the Union of South Africa, with promising results through controlling the vector *Frankliniella schultzei*.

Fusarium wilt of watermelons.—I, Effect of soil temperature on the wilt disease and the growth of watermelon seedlings, M. N. WALKER (*Florida Sta. Bul.* 363 (1941), pp. 29, figs. 8).—From the studies reported it is concluded that 27° C. is the optimum temperature for infection and injury of seedlings of the Tom Watson and Kleckley Sweet varieties by *F. bulbigenum nivolum*. The optimum for early infection is not particularly important, since with heavy soil infestation killing is practically the same at 20°-30° under exposure for as long as 30 days. Infection declined rapidly above 30° and practically ceased at 33°. The minimum temperature for infection was not determined. In the field other soil organisms may be complicating factors. Certain citrons were resistant to infection and wilt development, but their resistance appeared to be relative and infection and disease progress seemed merely to be slower than in watermelons. Tests of crosses of resistant citron with susceptible watermelons indicated the resistance to be recessive. Germination and early growth of watermelons and citrons were optimum at 31°-33°. Soil temperature effects were most marked during early growth stages, but later on air temperatures or other factors appeared more important at 24°-35°. There was some evidence that citron seedlings are somewhat more vigorous than those of watermelon and are also somewhat more tolerant of temperatures above 35°. Growth of the fungus appeared greatest at 27°, while the minimum was apparently slightly below 7.5° and the maximum about 38°.

The grey mould of fruit and some of its host plants, H. WORMALD (*Gard. Chron.*, 3. ser., 109 (1941), No. 2823, p. 44, fig. 1).—An eye rot of apples is associated with *Botrytis cinerea* on the calyx lobes. The occurrence of *Botrytis* is also reported on the dandelion, black-bryony, bramble, and sweet chestnut. Strains isolated from these hosts were shown capable of infecting apples.

Leaf variegation of the apple, C. E. COLE (*Jour. Dept. Agr. Victoria*, 39 (1941), No. 3, pp. 141-142, figs. 3).—From studies of this leaf variegation, said to be very common in Victorian orchards, it appears to be a virus disease of little economic importance transmitted by budding and grafting operations.

Control of apple blotch with "eradicator" fungicides, C. D. SHERBAKOFF and R. A. HYBE (*Tennessee Sta. Cir.* 77 (1941), pp. [3], fig. 1).—It is concluded from the tests reported that where summer sprays are used the eradicator spray cannot profitably be employed except when directed against insects or some disease other than blotch. Where Cu injury follows the early cover sprays, an eradicator spray should allow use of a "safer" fungicide—e. g., wettable S—in these sprays. Elgetol alone proved less effective for blotch than Keitt's eradicator spray (E. S. R., 85, p. 75) or the summer sprays.

Untersuchungen über den Apfelmehltau (*Podosphaera leucotricha* [Ell. u. Ev.] Salm) [Investigations of powdery mildew of apple], K. STOLL (*Forschungsdienst*, 11 (1941), No. 1, pp. 59-70, figs. 5).—An address reviewing the subject (8 references).

Methyl bromide and brown rot of stone fruits, L. L. CLAYPOOL and W. B. HAWITT. (Univ. Calif.). (*Blue Anchor*, 18 (1941), No. 2, pp. 25, 38).—From the tests reported it appears that methyl bromide may prove of some value as a

fungicide but that in concentrations and exposure times safe for fruit it has no value.

**Mathematical model of embryo abortion in Phillips Cling peaches**, G. A. BAKER. (Calif. Expt. Sta.) (*Jour. Agr. Res.* [U. S.], 64 (1942) No. 3, pp. 173-178).—Though it is practically impossible to observe the time of abortion of peach embryos, the frequency distributions of the lengths of normal embryos at intervals throughout the growing season and the frequency distribution of the lengths of aborted embryos at harvest time can be observed. It is assumed that at any one time the lengths of normal embryos are distributed according to a Pearson type III curve and that abortion does not cause a change in their measured lengths. On these bases and on observable data it was found possible to compute any desired number of moments of  $p(t)$ , the function which represents the probability of abortion at time,  $t$ . As a control, the close connection of embryo abortion with gumming is noted,  $p(t)$  being usually one-humped and paralleling the probability of gumming. Abortion occurs about 11 days before gumming. It is noted that  $p(t)$  may be two-humped, and this has a marked effect on the distribution of the lengths of aborted embryos observed at harvest time. It is not known whether the second hump in  $p(t)$  is associated with a corresponding increase in the probability of gumming. The observed facts appear to indicate the efficacy of the proposed model.

**Virus diseases of the peach** (*New Jersey Stas. Plant Disease Notes*, 19 (1941), Nos. 8, pp. 29-32; 9, pp. 33-36).—Symptoms and control are described, without references.

**Cherry yellows less severe in New York**, L. R. TEHON (*Amer. Nurseryman*, 74 (1941), No. 7, p. 24).—This virus disease is reported to be less severe in New York than in Wisconsin. Observations tend to indicate that at present it is transported into new areas by nursery stock.

**Diseases of strawberries**, J. B. DEMAREE (*U. S. Dept. Agr., Farmers' Bul. 1891* (1941), pp. 11-27, figs. 11).—This supersedes Farmers' Bulletin 1458 (E. S. R., 54, p. 149).

**Raspberry spur blight** (*New Jersey Stas. Plant Disease Notes*, 19 (1941), Nos. 5, pp. 17-20; 6, pp. 21-24).—The disease due to *Mycosphaerella rubina* is briefly described, and experiments and observations are presented leading to recommended culture practices which should tend to reduce losses from this infection. These include use of disease-free stock, avoidance of low, damp areas and excessive nitrogenous fertilization, keeping weeds down to permit free air circulation, and removal of dead canes.

**Forschungsaufgaben des weinbaulichen Pflanzenschutzes** [Research problems in plant protection as relating to grape culture], F. STELLWAAG (*Forschungsdienst*, 11 (1941), No. 2, pp. 153-160).—An address discussing the control of diseases and pests of grapes.

**Recherches sur les causes de la résistance au mildiou des vignes américaines et de leurs hybrides** [Studies on the causes of resistance of American grapes and their hybrids to mildew], I, II, L. RIVES and F. NYSTERAKIS (*Prog. Agr. et Vitic. (Éd. Est-Centre)*, 62 (1941), Nos. 10, pp. 168-170; 12-13, pp. 209-211).—Two papers are presented.

I. *Influence de la concentration du suc cellulaire: Mesures réfractométriques* [Influence of the concentration of the cell sap: Refractometric measurements].—It is concluded from the data presented that there is no close relationship between the concentration of the cell sap and resistance to mildew.

II. *Influence de l'acidité: Mesures de pH* [Influence of acidity: pH measurements.].—The authors found no consistent correlation between the pH of the cell sap and resistance to mildew.

**Mildew de la vid** [Downy Mildew of the grape], C. A. DANÍES L. and F. PEÑARANDA CANAL (*Rev. Facult. Nac. Agron. [Colombia]*, 4 (1941), No. 10, pp. 1009-1036, pl. 1, figs. 5).—A general account on the disease and its control and on the fungus (*Plasmopara viticola*) causing it.

**Pierce's disease of grapevines**, W. B. HEWITT. (Univ. Calif.). (*Blue Anchor*, 18 (1941), No. 3, pp. 16-21, 36, figs. 7).—A general account on this grape disease which is reported to be again killing vines in many California vineyards.

**Black measles and little leaf may be confused with Pierce's disease of grapevines**, W. B. HEWITT. (Univ. Calif.). (*Blue Anchor*, 18 (1941), No. 3, pp. 26-28, 40, figs. 4).—The two diseases are described and differentiated from Pierce's vine disease.

**Podridão do pé dos citrus** [Citrus foot rot], J. DE ALENCAR (*Ceres [Minas Geraes]*, 2 (1941), No. 12, pp. 488-496, figs. 3).—A general account of the *Phytophthora*-induced disease and its control in Brazil.

**The effects of phosphorus deficiency on citrus**, H. D. CHAPMAN and S. M. BROWN (*Hilgardia [California Sta.]*, 14 (1941), No. 4, pp. 161-181, pls. 2, figs. 2).—In connection with a fertilizer test on a calcareous Hanford fine sandy loam with young navel-orange trees in 55-gal. containers, an acute P deficiency of sudden onset developed in those receiving N or N plus K but no P. An abnormal shedding of leaves just after the spring bloom and 3 yr. after planting was the first indication of malnutrition, and other symptoms developing are described in detail and illustrated in color. The inorganic and total P in all parts of the tree were found to be subnormal, that in the bark and woody tissues being especially low. Fruit maturing on the P-deficient trees just prior to development of the leaf symptoms was a deeper orange color, with thicker rind and less juice than on the P-treated trees. A secondary Mn deficiency developed in the P-deficient trees, believed due to a decreased solvent power of the roots for the sparingly soluble Mn compounds of this soil, occasioned by diminished root respiration. A survey of commercial groves on similar soils showed no symptoms of P deficiency. That occurring in the experimental cultures is thought to have resulted in part from the restricted root development in the limited amount of soil available for root expansion. There are 18 references.

**The effects of sulfur deficiency on citrus**, H. D. CHAPMAN and S. M. BROWN (*Hilgardia [California Sta.]*, 14 (1941), No. 4, pp. 183-201, pls. 2, figs. 2).—A malnutrition condition developing in young navel-orange trees growing in a granite-derived soil in 55-gal. containers proved to be S deficiency, characterized by abnormal yellowing of the new-cycle growth and resembling the more or less uniform yellowing from N deficiency. In contrast to the latter, S-deficient leaves had a higher N content and a lower S content than normal, leaf analysis thus differentiating between the two troubles. Immature fruit on S-deficient trees were light yellowish green, and maturing fruit failed to develop the characteristic orange color. In the less severely affected fruit the contents of many of the juice vesicles were gelatinized, as in granulation. Other symptoms are detailed, including the results of chemical analysis. A certain degree of parallelism in composition was found between the S- and P-deficient trees. Though many western soils are low in total S, it is not believed that, except for isolated cases, commercial citrus orchards would benefit by sulfate fertilization, sufficient S to meet the requirements usually coming from other sources.

**Observations on the parasitism of Rosellinia pepo** Pat., J. M. WATERSTON (*Trop. Agr. [Trinidad]*, 18 (1941), No. 9, pp. 174-184, pls. 4, figs. 2).—Among the highly susceptible host plants noted are avocado, *Artocarpus* spp., *Erythrina* spp., *Inga laurina*, nutmeg, lime, coffee, and cacao, the last being the chief economically important host. In attempting to gage the factors in both

field and laboratory which control the physiology of parasitism in this fungus, analyses of soils within and adjacent to *Rosellinia* patches showed no relations of pH and of amounts of N, organic matter, or of available potash and phosphate with the incidence of infection. The disease was most frequently observed in Trinidad persisting in soils of light texture, and this point is stressed as of some significance in relation to studies of the water relationships of the soil. It was experimentally established that the rate of infection in cacao seedlings was most rapid in the drier and better aerated series, but it was not determined whether soil moisture could be reduced to the level where host and parasite might exist together without a parasitic relationship. There are 34 references.

**Recent investigations of interest to florists** (*New Jersey Stas. Nursery Disease Notes*, 14 (1941), No. 6, pp. 21-23).—Brief notes are presented on *Fusarium* wilt of sweet-william (*Dianthus barbatus*), *Sphaceloma* scab of poinsettia, and Ca deficiency as a factor in abnormal rooting of Philodendron cuttings.

**A wilt disease of godetias and other ornamental plants**, R. E. TAYLOR (*Ann. Appl. Biol.*, 28 (1941), No. 2, pp. 91-101, pl. 1).—"A wilt disease of godetia, clarkia, antirrhinum; and sweet-sultan (*Centaurea moschata*) caused by one or more species of pycnidial fungi is described. The fungi isolated from the various hosts have generally proved to be pathogenic to all of them when cross-inoculated. Other herbaceous ornamental plants are susceptible under experimental conditions. The various isolates are considered to be different strains of a single species which is provisionally identified as *Diplodina passerinii* Allesch., previously recorded as a parasite of antirrhinum. The fungus is a wound parasite and gains entrance to the host through the stem, frequently just above the soil and at the leaf-axils. There is no evidence of infection via the roots. The cultural characters of the isolates are compared."

**Chrysanthemums resistant to Verticillium wilt**, P. E. TILFORD. (Ohio Expt. Sta.). (*Chrysanthemum Soc. Amer. Bul.*, 9 (1941), No. 3, pp. 2-3).—As a result of 4-yr. tests of 423 chrysanthemum varieties, those found resistant are listed under eight groups on the basis of types of varieties.

**Botrytis crown rot of irises**, L. DODDALL. (Minn. Expt. Sta.). (*Minn. Hort.*, 69 (1941), No. 7, pp. 123-131, figs. 2).—A note on this iris disease and its successful control by treating the rhizomes with mercurials when they are transplanted and setting them in new soil.

**The spread of eelworm in commercial narcissus plantings**, A. BEAUMONT and L. N. STANILAND (*Ann. Appl. Biol.*, 28 (1941), No. 2, pp. 135-141, pl. 1, fig. 1).—*Anguillulina dipsaci* is introduced into commercial plantings by infested stock bulbs not given (or insufficiently) the hot-water treatment. Spread is chiefly by surface water and mostly in the direction of drainage. Tools, boots, and especially infested dried leaves in the cultivation operations are also means of spread. Narcissus leaves can become infected from January to May, and late infections are easily overlooked. In dry weather small numbers may persist from season to season. In commercial plantings, affected patches should be dug out completely and surrounded by a trench to prevent spread. Infested fields cannot safely be replanted for at least 3 yr. after the bulbs have been lifted. Field inspections are of value to the grower, but do not guarantee freedom from infestation.

**The use of fungicides on orchids**, A. G. KEVORKIAN and C. L. HORN. (P. R. Expt. Sta.). (*Amer. Orchid Soc. Bul.*, 9 (1941), No. 12, pp. 328-330, fig. 1).—Fungus diseases of at least three genera of orchids are said to cause much injury to the plants, and particularly to those that have recently been brought from the wilds for cultivation in the Tropics and Subtropics. Several fungicides, especially bordeaux mixture (4-4-50), have prevented disease spread in well-renovated plants without injury in the many treated genera.

**Root rot of *Ranunculus asiaticus* caused by *Pythium debaryanum*,** C. M. TOMPKINS and J. T. MIDDLETON. (Calif. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 64 (1942), No. 3, pp. 179-183, figs. 2).—The authors describe a destructive root disease of Persian buttercup (*R. asiaticus*) prevalent in commercial plantings in four coastal counties of California. Its development and spread are favored by excessive moisture, poor drainage, cool weather, and crowding. The chief symptoms are a general wilting followed by rapid collapse and death, and the roots, tubers, stems, and petioles may be affected. *P. debaryanum* has been consistently isolated and has proved pathogenic in greenhouse tests, and its morphology and temperature relations are discussed. The incubation period for the disease was 11-25 days. In greenhouse tests the fungus proved pathogenic to young plants of Iceland poppy, columbine, fibrous-rooted begonia, butterflyflower, and cucumber. Persian buttercup seedlings were also experimentally infected by *P. ultimum* and *P. irregulare*, with symptoms similar to those induced by *P. debaryanum*.

**Tests with new and old rose soil show value of sterilization,** F. F. WEINARD. (Univ. Ill.). (*Florists' Rev.*, 88 (1941), No. 2263, pp. 11-12).—Tests indicated sterilized old soil (steam and hot water used) to be about as good as new soil.

**Control black mold of rose grafts by chemical treatments,** D. B. CREAGER. (*Florists' Rev.*, 89 (1941), No. 2290, pp. 21-22, figs. 2).—In the experiment reported, by the Illinois Natural History Survey, all four chemicals tested reduced infection by *Chalaraopsis thielavioides* and increased the number of plants grafting successfully. The best control was obtained with calcium hypochlorite, but with fewer plants successfully grafting than with the other materials. Semesan delayed graft union and scion development but gave good mold control. Potassium permanganate gave the poorest control, but its apparently stimulative effect resulted in the largest number of successful grafts. Good mold control was obtained with formaldehyde, and the number of successful grafts was only slightly less than with the preceding. A rapid method of testing the effectiveness of disinfectants is described.

**Bulb rot of *Scilla nutans* [nonscripta] caused by *Penicillium cyclopium*** Westling, B. SINGH (*Brit. Mycol. Soc. Trans.*, 25 (1941), pt. 2, pp. 194-199).—This fungus was isolated from rotted bulbs of common blue squill and its pathogenicity proved. The symptoms of infection and the fungus itself are described. Fungicidal tests gave inconclusive results, but the disease was found to be worse in wet soils and when the bulbs were stored under high humidity and temperature.

**Spread of snapdragon rust in Europe,** E. LEPK. (*Internat. Bul. Plant Protect.* [Roma], 15 (1941), No. 5, p. 93M, fig. 1).—The present distribution of *Puccinia antirrhini* in Europe is outlined and mapped.

**Root rot of young, grafted dogwood** (*New Jersey Stas. Nursery Disease Notes*, 14 (1941), No. 5, pp. 17-20).—This is a preliminary report of studies of a root rot of pink dogwood associated with *Pythium* sp., including control.

**Your shade trees: Summer shade tree problems,** P. P. PIRONE (*Amer. Forests*, 47 (1941), No. 6, pp. 296-297, figs. 3).—Notes on diseases and other disturbances of shade trees, including oaks, planes, elms, lindens, and chestnuts.

**Reducing losses from tree diseases in eastern forests and farm woodlands,** G. H. HEPTING (*U. S. Dept. Agr., Farmers' Bul.* 1887 (1942), pp. [2] + 22, figs. 9).—"A ready reference on diseases for both the forester and the farmer in the East."

***Halalophragmium ponderosum* Syd. on *Acacia leucophloea* Willd.,** M. J. THIRUMALACHAR (*Jour. Indian Bot. Soc.*, 20 (1941), No. 5-6, pp. 293-298, pl. 1, figs. 4).—A study of this rust fungus, with comparison of the tumors induced to crown gall.

**Chestnut breeding work in 1940**, A. H. GRAVES (*Brooklyn Bot. Gard. Rec.*, 30 (1941), No. 2, pp. 87-93).—Progress is reported on the problem of developing a chestnut tree suitable for timber and at the same time resistant to chestnut blight.

**Iron chlorosis in tree windbreaks**, H. E. WAHLBERG (*Calif. Citrog.*, 26 (1941), No. 8, p. 228).—Occurrence noted in eucalyptus trees in southern California.

**Preliminary investigation of oak diseases in Illinois**, J. C. CARTER (*Ill. Nat. Hist. Survey Bul.*, 21 (1941), Art. 6, pp. 191-230, figs. 52).—In studies of 11 species of oaks in Illinois it was found that cankers, dieback, twig blight, and root rot are important in the decline and death of trees both in nursery, shade, and ornamental plantings and in native stands. Numerous fungi, 22 of which are here described, were associated with cankers, deep wood infections, dieback, and twig blight. Those associated most consistently with canker and dieback were species of *Dothiorella*, *Coryneum*, *Cytospora*, *Nummularia*, *Diatrype*, and *Phomopsis*. Those principally associated with cankers were species of *Phoma*, *Fusicoccum*, *Sphaeropsis*, and *Bulgaria*, and with dieback species of *Coniothyrium* and *Pyrenochaeta*. These fungi can develop on dead wood, but many of them are potential parasites of oak trees, especially when the latter are growing under adverse conditions. Successful inoculations on oak species were made with *Dothiorella quercina* and *Coryneum kunzei*.

**A needle blight of Austrian pine**, R. L. HULBARY (*Ill. Nat. Hist. Survey Bul.*, 21 (1941), Art. 7, pp. [2]+231-236, figs. 4).—In blighted needles of *Pinus nigra austriaca* collected in northern Illinois in the fall of 1938, immature stromata indicated the cause of the disease. They remained quiescent out-of-doors through the winter but by March 1 had emerged as strongly erumpent, loaf-shaped structures, and 1.5 mo. later pycnidial locules were becoming differentiated and by May 15 conidia were being produced. The fungus is described as *Dothistroma pini* n. gen. and sp. in the scolecosporous division of the Phomaceae.

**Results of the survey of the little-leaf disease of southern pines in Alabama (a preliminary report)**, W. R. BOGGESE, P. A. SWARTHOUT, and E. R. TOOLE (*Alabama Sta.*, 1941, pp. [2]+15, figs. 2).

**Blister rust in 1940**, L. R. TEBON (*Amer. Nurseryman*, 73 (1941), No. 8, pp. 26-27).—This note summarizes the extension of infected areas in the United States (E. S. R., 83, p. 360).

**Treatment of white pines infected with blister rust**, J. F. MARTIN and G. F. GRAYATT (*U. S. Dept. Agr., Farmers' Bul.* 1885 (1942), pp. II+28, figs. 14).—This replaces Department Circular 177 (E. S. R., 45, p. 753).

**Canker-stain disease of planetrees**, P. V. MOOK. (U. S. D. A.). (*Trees Mag.*, 4 (1941), No. 3, pp. 7, 15, 16, 18, figs. 4).—This is a general account of the present status of the disease due to *Endoconidiophora* known to affect American and London planetrees (*Platanus occidentalis* and *P. acerifolia*, respectively), including the known distribution in the eastern United States, the symptoms, mode of dissemination, and means of prevention and control.

**Species of Stigmata and Stigmella occurring on Platanus**, D. J. and C. O. SMITH (*Hilgardia [California Sta.]*, 14 (1941), No. 4, pp. 203-231, figs. 10).—On the basis of morphological and physiological differences and of host specificity, it is indicated that three distinct species of fungi are involved in leaf spots on planetrees, viz, *Stigmata platani* on *P. orientalis* alone, *Stigmella platani-racemosae* on *P. racemosa*, and also proved capable of infecting *P. wrightii*, and the fungus here named *Mycosphaerella polymorpha* n. comb. (= *M. stigmata-platani*) on *P. occidentalis* and proved pathogenic also for *P. racemosa*, *P. wrightii*, and *P. acerifolia* but not for *P. orientalis*. The last fungus produced

conidia ranging from typical *Stigmina* to *Cercospora* types and hitherto unnamed because erroneously identified with *S. plantani*. The *Mycosphaerella* stage, it is believed, may be identical with *M. platanifolia*, and *S. visianica* appears to be identical with the conidial stage. Each of these species has been isolated and grown in pure cultures, and is discussed in detail. There are 25 references.

Zonnebrand bij Hevea [Sunscald of Hevea], R. VAN DER VEEN (*Bergcultures*, 15 (1941), No. 11, pp. 314-317, fig. 1).—On the disease of Para rubber trees due to infection by *Diplodia* (*Botryodiplodia theobromae*).

Over de bestrijding van eenige ziekten, die houtwonden aan het onderste deel van den stam van hevea veroorzaken [Control of some diseases causing wounds on the lower part of the trunk of the Para rubber trees], W. H. DE JONG (*Bergcultures*, 15 (1941), No. 33, pp. 1134-1137).

New methods for the cultivation of wood-rotting fungi, E. C. BADCOCK (*Brit. Mycol. Soc. Trans.*, 25 (1941), pt. 2, pp. 200-205, pl. 2).—A new medium is described, consisting of sawdust of a readily decayed species of wood such as beech or spruce, well mixed with 5 percent by weight of an accelerator, the principal ingredients of which are corn meal and bonemeal. On this medium exceptionally good growth of a wide range of species was obtained. The method is suggested for resistance tests of treated wood samples. Adding the accelerator to garden soil or to cotton wool also made a medium on which vigorous growth developed.

Chemical treatment of wet mechanical pulp in order to control damages caused by fungi, E. RENNERTFELT (*Svenska Skogsvårdsför, Tidskr.*, 39 (1941), No. 1, pp. 19-94, figs. 17; *Swed. abs.*, pp. 89-92).—Following a review of previous attempts at avoiding fungus injuries to pulpwood, the author describes laboratory tests with different fungicides on artificial substrata and on wet mechanical pulp and chemical treatment tests of pulp at the mills, and the effects of the chemicals on the composition and growth of the fungus flora. Good results are reported at several mills with ethyl mercury chloride, and factory-scale experiments with this fungicide also proved favorable.

A manual of agricultural helminthology, I. N. FILIPJEV and J. H. SCHUURMANS STEKHOVEN, JR. (*Leiden [Netherlands]: E. J. Brill*, 1941, pp. XV+878, figs. 460).—The five parts of the book concern general morphology and biology of nematodes, systematics, technical methods for collection and preparation, plant-parasitic nematodes, and insect parasites. A supplement considers the closely related Gordiaceae or Nematomorpha. Over six pages of literature references to insect parasites are included.

Verbreitung und Schadwirkung des Stockälchens (*Anguillulina dipsaci*) in Schleswig-Holstein [The distribution of and damage by the stem nematode in Schleswig-Holstein], H. GOFFART (*Ztschr. Pflanzenkrankh. u. Pflanzenschutz*, 51 (1941), No. 2, pp. 97-102, figs. 2).—Data on the relative damage by months and on the numbers of nematodes according to soil depth are included, and the relative susceptibilities of 25 species of plants in 10 families are tabulated.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

American wild life, illustrated (*New York: Wise & Co.*, [1940], pp. [2]+XIV+749, pls. 6, [figs. 326]).—This is a compilation that was prepared by the Writers' Program of the Work Projects Administration in the city of New York.

[Work in game management by the Wisconsin Station] (*Wisconsin Sta. Bul.* 453 (1941), pp. 58-60, fig. 1).—Studies briefly reported (*E. S. R.*, 83, p. 82) by A. Leopold and A. Hawkins relate to the Riley Game Cooperative in

western Dane County and the history of the Faville Grove area in Jefferson County.

The "gopher" (*Citellus richardsonii* (Sabine)) as an experimental host for *Trichinella spiralis*, E. P. OFFUTT, JR., and O. R. MCCOY (*Jour. Parasitol.*, 27 (1941), No. 6, pp. 535-538).—It has been found that *C. richardsonii* is very susceptible to infection with *T. spiralis*, 10 of 14 animals fed doses as small as from two to five larvae per gram of body weight having succumbed. Adult worms persisted in the intestines of most animals for long periods of time, 13 weeks being the maximal period observed. Five gophers that were reinfected showed no resistance to the test doses of larvae that were employed.

The snowshoe hare a new host of *Dermatoxys veligera* and *Nematodirus leporis*, A. B. ERICKSON (*Minnesota Sta. Rpt.* 1941, pp. 39-40).—The nematode parasites *Dermatoxys veligera* to the number of 42 and *Nematodirus leporis* to the number of 33 are recorded as having been found by the author to infest a single snowshoe hare (*Lepus americanus phaeonotus*) collected at Lake Alexander in June 1934 and 10 specimens of *D. veligera* to infest a hare collected near Lake Mille Lacs in January 1933.

Rat mite dermatitis in Minnesota, W. A. RILEY. (Univ. Minn.). (*Minn. Med.*, 23 (1940), No. 6, pp. 423-424).—The tropical rat mite, which is the cause of a severe dermatitis and has been reported as a vector of epidemic typhus in Texas, with more than 200 cases brought to attention, is for the first time reported as far north as Minnesota, where four widely separated localities are cited.

Rat control, G. C. DECKER, H. GUNDERSON, and H. J. BARRE (*Iowa Sta. Bul.* P33, n. ser. (1941), pp. 105-123, figs. 13).—A practical account of the rat, its economic importance and control by means of poison baits, fumigation, and traps, and of methods of rat-proofing farm buildings.

Food habits of the prairie spotted skunk in southeastern Iowa, W. D. CRABB. (Iowa Expt. Sta. coop. Iowa State Col. et al.). (*Jour. Mammal.*, 22 (1941), No. 4, pp. 349-364, figs. 11).—Report is made of an investigation of the food of *Spilogale interrupta* (Raf.).

The stomach worm *Obeliscoides cuniculi* in the woodchuck, F. G. WALLACE. (Univ. Minn.). (*Jour. Wildlife Mangt.*, 6 (1942), No. 1, p. 92).—The stomach worm *O. cuniculi* of domestic and wild rabbits, in which host it has been found in various parts of the country, is recorded as found in the stomachs of six woodchucks collected in Minnesota in numbers from 6 to 128.

Analysis of losses in the nesting of birds, S. C. KENDEIGH. (Univ. Ill. et al.). (*Jour. Wildlife Mangt.*, 6 (1942), No. 1, pp. 19-26, fig. 1).—Report is made of the percentage of successful and unsuccessful outcomes in 2,725 nesting attempts of 51 species of mostly forest-edge birds and the percentage of all eggs laid to develop into fledglings, based upon observations near Cleveland, Ohio.

The role of the burrowing owl and the sticktight flea in the spread of plague, C. M. WHEELER, J. R. DOUGLAS, and F. C. EVANS. (Univ. Calif.). (*Science*, 94 (1941), No. 2450, pp. 560-561).—Report is made of the study of a plague epizootic in progress among ground squirrels (*Citellus beecheyi*) of Kern County, Calif., during the spring and summer of 1941. Among fleas collected from the ground squirrels in nearby areas was the sticktight flea, a species of extremely wide geographical and hostal occurrence in the United States. It was abundant on chickens and other domestic fowl, on rats and various wild rodents, and on such predators as the coyote, Cooper's hawk, and burrowing owl. One of these hosts, the burrowing owl (*Speotyto cunicularia*), taken on a ranch about 5 miles west of the plague area, yielded 70 individuals of this flea, which upon mass inoculation into a test guinea pig proved to be infected with

plague organisms. This appears to be the first record of a bird host as a carrier of plague-infected parasites and the first demonstration of natural plague infection in this species of flea.

The susceptibility of sage grouse to strychnine, J. C. WARD, M. MARTIN, and W. ALLED (*Jour. Wildlife Mgmt.*, 6 (1942), No. 1, pp. 55-57).—In the experiments conducted the sage grouse did not voluntarily eat poisoned grain, and when it was force-fed it tolerated quantities so large that it is believed that the exposure of strychnine in this form is no hazard for these birds. Since under normal conditions the grouse ate small quantities of alfalfa leaves treated with strychnine and the amounts eaten were increased when the birds were starved, this bait should be used with caution.

Devise control for disease of trout (*Wisconsin Sta. Bul.* 453 (1941), p. 63).—Reference is made to the development by L. L. Gee and W. B. Sarles of a method which makes use of acriflavine in disinfecting trout eggs to control furunculosis, a disease due to *Bacterium salmonicida*, which has killed from 80 to 95 percent of the fish in some hatcheries.

The polyclad *Hoploplana inquilina thaisana* Pearse, 1938, from the mantle cavity of oyster drills, L. A. STAUBER. (N. J. Expt. Stas.). (*Jour. Parasitol.*, 27 (1941), No. 6, pp. 541-542).

Entomological nomenclature and literature, W. J. CHAMBERLIN (*Ann Arbor, Mich.: Edwards Bros.*, 1941, pp. IX+103, [figs. 2]).—Part 1 of this work deals with entomological nomenclature (pp. 1-44) and part 2 with entomological literature (pp. 45-103).

[Work in entomology of the Department] (*U. S. Dept. Agr., Sec. Agr. Rpt.*, 1941, pp. 233-237).—The military importance of war on insects, defense applications of entomology, and tests of new insecticides are discussed.

[Contributions on economic insects, insecticides, and insect control] (*U. S. Dept. Agr., Bur. Ent. and Plant Quar.*, 1941, E-541, pp. 8; E-542, pp. 4; E-543, pp. 8; E-544, pp. 8; E-545, pp. 18, pl. 1; E-546, pp. 14; E-547, pp. 5; E-548, pp. 12; E-549, pp. 11; E-550, pp. 8).—The following contributions are in continuation of this series (E. S. R., 85, p. 501): Control of Dog Fly Breeding in Beach Deposits of Marine Grasses, by S. W. Simmons and W. E. Dove (E-541); Control of Dog Fly Breeding in Peanut Litter, by W. E. Dove and S. W. Simmons (E-542); Further Results From Airplane Dusting in Arizona for Hemipterous Cotton Insect Control, Crop Season of 1940, by T. P. Cassidy and T. C. Barber (E-543) (E. S. R., 80, p. 365); Toxicity of Pyrethrins I and II in Kerosene to the American Cockroach, by E. R. McGovran, E. L. Mayer, and F. Acree, Jr. (E-544); A Report of Investigations of the Extent and Causes of Heavy Losses of Adult Honeybees in Utah, by A. P. Sturtevant, G. F. Knowlton, J. D. Hitchcock, G. H. Vansell, E. C. Holst, and W. P. Nye (E-545) (coop. Utah and Wyo. Expt. Stas.); An Experimental Cooperative Community Program for the Cultural Control of Bugs of the Genus *Lygus* on Alfalfa Seed Crops in the Mohawk Area of Arizona in 1939 and 1940, by L. L. Stitt (E-546) (coop. Univ. Ariz. et al.); The Corn Earworm on Lima Beans and Its Control, by L. W. Brannon (E-547) (coop. Va. Truck Sta.); Phthalonitrile as an Insecticide, by M. C. Swingle, J. B. Gahan, and A. M. Phillips (E-548); 1,4-Diphenyl Semicarbazide as an Insecticide, by J. B. Gahan, M. C. Swingle, and A. M. Phillips (E-549); and *p*-Aminoazobenzene Hydrochloride as an Insecticide, by A. M. Phillips, M. C. Swingle, J. B. Gahan, and E. R. McGovran (E-550).

[Entomological investigations by the Georgia Station] (*Georgia Sta. Rpt.* 1941, pp. 112-119, figs. 3).—A report which mentions progress (E. S. R., 84, p. 74) on the cowpea curculio, tomato fruitworm, southern corn rootworm,

Mexican bean beetle, green June beetle, green bug, bollweevil, pale-striped flea beetle, and the wooly alder aphid.

[A report of entomological work in South Australia in 1940] (*Univ. Adelaide, So. Austral., Waite Agr. Res. Inst. Rpt., 1939-40, pp. 35-39*).—The work considered relates to grasshopper problems, several agricultural and horticultural crop pests, and insects affecting stored foodstuffs and stored wheat.

Insects as carriers of poliomyelitis virus, C. T. BRUES (*Science, 95 (1942), No. 2459, pp. 169-170*).

Control of insects and mites attacking narcissus bulbs, C. F. DOUCETTE (*U. S. Dept. Agr., Farmers' Bul. 1890 (1941), pp. [2]+25, figs. 22*).—This publication discusses the stages, seasonal development, and nature of attack of the narcissus bulb fly, the lesser bulb fly, *Eumerus strigatus* Fallen, *B. narciissi* Smith, the bulb mite, and the bulb-scale mite *Tarsonemus laticeps* Halbert. General control measures, including fumigation and hot-water and vapor-heat treatment, are summarized.

Insecticidal efficiency of some oils of plant origin, A. W. CRESSMAN and L. H. DAWSEY (*U. S. Dept. Agr., Tech. Bul. 801 (1942), pp. 15, figs. 4*).—Certain oils of plant origin were compared for insecticidal efficiency with a refined petroleum oil. Crude cottonseed, crude corn, and peanut oils on the basis of equivalent oil deposits were equal or superior to petroleum oil for Mexican mealybug control, and crude corn oil gave higher kills and heavier oil deposits than petroleum on the willow scurfy scale *Chionaspis salicis-nigrae* (Walsh) and the oystershell scale. Refined corn oil was less effective than petroleum oil for Mexican mealybug and oystershell scale control. In the case of the oystershell scale and *C. salicis-nigrae*, percentage of survival increased with density of infestation. For mealybugs, refined cottonseed oil was less effective than petroleum oils. Coconut oil plus petroleum oil gave smaller oil deposits and killed fewer mealybugs than an equivalent concentration of petroleum oil alone. Orange and pine oils were volatile, severely injured chrysanthemum plants, and had little effect on mealybugs. Tests indicated ovicidal efficiency was correlated with drying properties. Crude corn oil deposits were from 60 to 100 percent higher than those obtained from equivalent concentrations of other oils. Plant tolerance to different oils varied considerably. It was suggested that although vegetable oils are generally higher priced than petroleum oils they possess superior solvent action for certain organic insecticides and may find new uses because of this property.

Plantas ictiotóxicas: Farmacologia da rotenona [Ichthyotoxic plants: Pharmacology of rotenone], C. E. CORBETT ([*Sao Paulo*]: *Univ. Sao Paulo, 1940, pp. 157, pls. 24; Eng. abs., pp. 150-152*).—The first part of this work (pp. 5-73) emphasizes the importance of studies of fish-poisoning plants and reports upon the active principle rotenone, its extraction and standardization, and experimental studies recorded in the literature. Part 2 (pp. 75-148) deals with the new work on rotenone toxicity, including experiments conducted with both invertebrates and vertebrates. Ninety-one references to the literature are included in a bibliography.

Two genera of Symphylla new to the United States, with descriptions of three new species, A. E. MICHELbacher. (*Univ. Calif.*). (*Ann. Ent. Soc. Amer., 34 (1941), No. 1, pp. 139-150, figs. 4*).—Three species representing the genus *Symphylelopsis* are described as new, and notes are given on the genus *Geophilella* and the species *G. americana* (Hilton).

Life history notes on some West Indian coenagrionine dragonflies (Odonata), J. G. NEEDHAM (*Jour. Agr. Univ. Puerto Rico [Univ. Sta.], 25 (1941), No. 3, pp. 18, pl. 1*).

**Roach control:** A study of the relative efficiency of various commonly used insecticide dusts against roaches, H. LAUDINI and H. L. SWEETMAN. (Mass. State Col.). (*Soap and Sanit. Chem.*, 17 (1941), No. 6, pp. 129, 131, 133, 135).—In the tests reported the German cockroach was found much easier to kill than the American cockroach. Sodium fluoride was the most effective against the German cockroach, but was slightly less effective against the American cockroach. Pyrethrum alone was not very effective against either species in the runway tests, but was very effective if the dusts were applied directly on them. The addition of pyrethrum, from 10 to 33 percent of the total, to sodium fluoride increased the effectiveness of the poisons against the American cockroach and gave complete kills against the German cockroach. Pyrethrum and borax mixtures showed some promise against both species, but the slow action of the borax is objectionable.

**The genus *Aeoloplides* (Orthoptera) in Utah**, W. W. HENDERSON. (Utah Expt. Sta.). (*Utah Acad. Sci., Arts, and Letters, Proc.*, 18 (1940-41), pp. 83-89, pl. 1).—Two of the seven recognized species of Orthoptera of the genus *Aeoloplides* are known to occur in Utah, namely, *A. tenuipennis* (Scudder) and *A. chenopodii* (Bruner).

**The cattle lice of Great Britain, I, II**, H. J. CRAUFURD-BENSON (*Parasitology*, 33 (1941), No. 3, pp. 331-358, figs. 5).—This contribution is presented in two parts.

I. *Biology, with special reference to *Haematopinus eurysternus** (pp. 331-342).—Record is made of the geographical distribution of cattle lice in Great Britain, of which the cattle biting-louse (*Bovicola bovis*) is the most common and widely distributed species. The incubation period for the eggs was found to be as follows: The short-nosed cattle louse (*H. eurysternus*) 9-19 days (average 12), the cattle biting-louse 7-10 (average 8), *Linognathus vitula* 10-13, and *Solenopotes capillatus* 10-13 days. "With eggs of *H. eurysternus* it was found that the higher the minimum air temperature the shorter was the incubation period. In *H. eurysternus* the average length of the instars was first, 4 days; second, 4 days; third, 4 days; [and] preoviposition period, 3-4 days. The average time for the complete life cycle, egg to egg, was 28 days. The maximum longevity of *H. eurysternus* on the host was males 10 days, female 16 days. No males or females of *H. eurysternus* survived a starvation period of 72 hr. at 20° C. and relative humidity 70, or 0°-10° and r. h. 70-85, but some nymphs survived this period at 20° and r. h. 70, but none survived 96 hours' starvation. The maximum number of eggs recorded for one female was 24, and eggs were laid at the rate of 1-4 a day. The threshold of development of the eggs of *H. eurysternus* appears to be about 27.5°."

II. *Lice populations* (pp. 343-358).—Studies made of monthly examinations of cattle have shown the seasonal variations of the populations of these four species of cattle lice to be similar.

**On the biology of *Dysdercus howardi* Ballou.**—II, The effect of continued inbreeding on the life history, E. I. MACGILL (*Bul. Ent. Res.*, 32 (1941), No. 3, pp. 185-190).—This continues work noted (E. S. R., 73, p. 814).

**The ecology of the bed-bug (*Cimex lectularius* L.) in Britain:** Report on research, 1935-40, C. G. JOHNSON (*Jour. Hyg. [London]*, 41 (1941), No. 4, pp. 345-461, figs. 39).

**The nature of injury to alfalfa caused by *Empoasca fabae* (Harris)**, J. T. MEDLER (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 2, pp. 439-450, pls. 2).—It has been shown by a histological study of the feeding punctures of *Aceratagallia sanguinolenta* (Prov.) and *Macrosteles divinus* (Uhl.) that these leafhoppers cause no apparent internal injurious effect in alfalfa leaflets. The nature of

plant injury by the potato leafhopper is unique and a combination of the insect's feeding habit in vascular tissue and the action of a specific compound injected during its feeding process. This secretion causes hypertrophy in affected cells, and its effect is first characterized by nuclear enlargement and prominent safranin-stained nucleoli. It is conceivable that the hypertrophied cells cause an interruption of translocation processes which initiate secondary external symptoms of chlorosis or reddening in alfalfa leaves.

**Peregrinus maidis** (Ashm.) and the transmission of corn mosaic.—I, Incubation period and longevity of the virus in the insect, W. CARTER. (Hawaii. Pineapple Prod. Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 3, pp. 551-556).—In its hemipterous vector *P. maidis* the incubation period of the virus of corn mosaic varies normally from 11 to 29 days, with an equal distribution of cases between these two extremes. Feeding of the insects on an artificial culture solution during the incubation period did not appear to result in any lengthening of the period. The virus persists in the insect and in the majority of cases is transmitted without interruption to a series of plants when 2-day feeding periods are allowed. In some cases breaks in the succession of positive transmittals occurred. The transmittal succession was frequently interrupted by the death of the insect, but some individuals lived for a considerable period following the last positive transmittal, indicating that the virus content of the insect was exhausted. The disease has a latent period of development in the plant as short as 4 days, with a maximum of 24 days when the growth of the test plant was retarded.

The genus **Drepanaphis** Del Guercio east of the Rocky Mountains, C. F. SMITH. (Univ. N. C.). (*Jour. Elisha Mitchell Sci. Soc.*, 57 (1941), No. 2, pp. 226-242, figs. 9).—Of the 10 species of aphids of the genus *Drepanaphis* here considered, 6 are described as new to science. Five species were found by the author on the same sugar maple tree at the same time.

Studies of western aphids, G. F. KNOWLTON. (Utah Expt. Sta.). (*Utah Acad. Sci., Arts, and Letters, Proc.*, 18 (1940-41), pp. 65-68).—An annotated list of Aphidae of western United States which includes host plant range and distribution.

The genus **Aspidiotus** (Homoptera: Coccoidea: Diaspididae), G. F. FERRIS (*Microentomology*, 6 (1941), No. 2, pp. 33-69, figs. 8).—Twelve species of the genus *Aspidiotus* are recognized, of which 3 may prove to be synonyms. A list of 530 names, including homonyms, that have at some time or other been employed in *Aspidiotus* and a key to the species are included.

Observations on the morphology of the corn seed beetle **Agonoderus pallipes** Fab. (Carabidae), H. R. BEYSON and G. F. DILLON. (Kans. Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 1, pp. 43-50, figs. 17).—A detailed description is given of the adult corn seed beetle *A. pallipes* and a brief description of the egg, larva, and pupa.

Coleoptera associated with stored Nepal barley in Peru, H. E. HINTON (*Bul. Ent. Res.*, 32 (1941), No. 3, pp. 175-183, figs. 7).—Five species are considered, two of which are new. The genus *Eufalloides* is erected.

The Lathridiidae of economic importance, H. E. HINTON (*Bul. Ent. Res.*, 32 (1941), No. 3, pp. 191-247, figs. 67).—A total of 30 species of Coleoptera, family Lathridiidae, have been recorded from stored food products or have been found in warehouses, granaries, or mills. The life histories of five, namely, *Coninomus nodifer* (Westwood), *Enicmus minutus* (L.), *Cartodere flum* (Aubé), *C. fliformis* (Gyll.), and *Corticaria fulva* (Comolli), have been worked out, together with a nearly completed life history of the sixth (*Adistemia watsoni* (Wollaston)). A four-page list of references to the literature is included.

**Revision of the bark beetles belonging to the genus *Pseudohylesinus*** Swaine, M. W. BLACKMAN (*U. S. Dept. Agr., Misc. Pub. 461 (1942), pp. 32, figs. 3*).—The genus *Pseudohylesinus* is characterized, and a key is included for the separation of the known species. Seven new species are described. The hosts and distribution are recorded for all species. Three pages of figures useful for specific separation are included.

**Biology of the black blister beetle (Coleoptera: Meloidae)**, W. R. HORSFALL. (Ark. Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 1, pp. 114–126, figs. 10).—The author has found that the black blister beetle may have either a normal complete metamorphosis or a hypermetamorphosis, and that in either event there are five feeding larval instars that are morphologically very similar. Following them may be two supernumerary instars which do not feed. The sixth instar of coarctate larva is the only one of the seven which does not resemble the others closely. Therefore, there are one or two larval forms accordingly, as there are five or seven larval instars. The whole larval period usually requires about 10 mo. in the field, but in the laboratory the period may be completed within an average of 28 days. In the field the greater part of the period may be spent as an egg, a first-instar larva, or as a sixth-instar larva. Adults of this species emerge in late summer and may be collected until mid-November in northwestern Arkansas. They feed on the pollen of goldenrod and asters and not on foliage. Eggs are deposited in masses of about 165 eggs at the bottom of tubular cavities in the soil. These hatch in about 15 days under favorable conditions, or hatching may be delayed some months during unfavorable temperatures. Larvae feed on eggs of grasshoppers.

**Raspberry fruitworms and related species**, H. S. BARBER (*U. S. Dept. Agr., Misc. Pub. 468 (1942), pp. 32*).—A key is presented for distinguishing 13 named forms of raspberry fruitworms, including 4 from Europe, 2 from Asia, and 7 from the United States. Specific and generic names for the group are discussed. Descriptions, notes, and records for the forms mentioned, a chronological review of the literature involved, and names used in this discussion of *Byturus* are also included.

**The sand wireworm**, J. N. TENNET (*U. S. Dept. Agr. Leaflet 212 (1941), pp. 8, figs. 6*).—A practical account.

**Monograph of the South American weevils of the genus *Conotrachelus***, K. FIEDLER (*London: Brit. Mus. (Nat. Hist.)*, 1940, pp. V+365, [pl. 1, figs. 57]).—This work deals with weevils of the curculionid genus *Conotrachelus* of South America, which are separated into six groups and numerous subgroups. A table for the separation of the groups and tables for the separation of the species of each subgroup are included. Five hundred and fifty-five species are recognized, of which 409 are described as new. The body of the work appears in German.

**Control of strawberry root-infesting weevils**, G. F. KNOWLTON and R. L. JAMES. (Utah Expt. Sta.). (*Utah Acad. Sci., Arts, and Letters, Proc.*, 18 (1940–41), pp. 47–53, figs. 3).—In control experiments with poisoned baits sodium fluosilicate gave better results than calcium arsenate or sodium fluoride, whether combined with ground dried apples, raisins, or prunes plus bran or used with bran alone. It is pointed out that any carrier used may be combined with any chemical listed without materially changing the value of the chemical as a bait insecticide. First baiting should be done approximately 12 to 14 days after adult weevil emergence begins and before any eggs are laid. Baiting is necessary during the picking season and should not be postponed until after the strawberry crop is harvested. A second baiting treatment should be applied approximately 2 weeks after the first; this to destroy later emerging weevils and those missed by the first control application. In an appended note it is pointed out that during

the season of 1940 a number of farmers in Utah County applied grasshopper bait consisting of wheat bran 400 lb., sodium arsenite—4 lb. material—2 gal., and water from 35 to 45 gal. to their strawberry root weevil-infested fields, the applications being made with a teaspoon in a manner similar to that in which a poisoned dried-fruit bait is applied, and obtained substantial control. It is concluded that this type of bait, if satisfactory, would be less expensive and more easily prepared than any of the dried-fruit baits.

**Topping cotton in early fall as a possible means of reducing the spring boll weevil population in the northwestern part of the Florida sea island cotton belt.** P. W. CALHOUN (*Fla. Ent.*, 24 (1941), No. 2, pp. 35-40).

The utilization of certain nitrogenous and carbohydrate substances by the southern armyworm (*Prodenia eridania* Cram.), H. H. CROWELL (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 2, pp. 503-512, fig. 1).—Description is given of a method by which known quantities of bean leaves raised under standard conditions of light, moisture, and nutrition could be fed to fifth- and sixth-instar larvae of the southern armyworm. Under laboratory conditions southern armyworm larvae of the last two instars (fifth and sixth) were found to consume 97 percent of the total amount of food eaten during larval development. On dry weight basis, 10.787 gm. of food eaten by 60 larvae during the last two instars produced 5.5504 gm. of excrement with a gain in weight of larvae of 3.6183 gm. This represents 48.5-percent efficiency of utilization and 33.5-percent efficiency of conversion of foodstuff into dry body weight. Chemical analyses of the food leaves and excrement of fifth- and sixth-instar southern armyworm larvae showed that this insect utilizes most of the protein, reducing sugars, and sucrose in the leaves. They also use the nitrogen of naturally occurring amino acids and amides, but do not use nitrate nitrogen. Starch is not utilized, although the presence of a starch-splitting enzyme was verified.

**Fruitworm control** (*Miss. Farm Res. [Mississippi Sta.]*, 4 (1941), No. 12, p. 7).—Experiments with two dust preparations for the control of the tomato fruitworm showed a reduction of injury with 50 percent Kryolite, while 8 percent Rotenone was ineffective.

**A luminous fly larva with spider traits** (Diptera: Mycetophilidae), B. B. FULTON. (N. C. Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 2, pp. 289-302, pls. 2).—A study of the mycetophilid dipteran *Platyura fultoni* Fisher, luminous larvae of which have been found in wet, shaded places about springs and streams in the southern Appalachians, is reported. One larva was found parasitized by an undescribed species of an internal hymenopterous parasite of the genus *Dallatorrea*.

**Synopsis of the tachinid flies of the genus Tachinomyia, with descriptions of new species.** R. T. WEBBER (*U. S. Natl. Mus. Proc.*, 90 (1941), No. 3108, pp. 287-304, fig. 1).—Nine species of tachinid flies of the genus *Tachinomyia* are recognized, of which four are described as new.

**The interconversion of foodstuffs in the blowfly (*Phormia regina*) during metamorphosis, I-III.** (Ohio State Univ.). (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 1, pp. 17-37, figs. 4).—This contribution is presented in three parts as follows: Part 1, Respiratory Metabolism and Nitrogen Excretion, by F. A. Hitchcock and J. G. Haub (pp. 17-25); part 2, Changes in Composition as Determined by the Oxycalorimeter, by M. B. Patton, F. A. Hitchcock, and J. G. Haub (pp. 26-31); and part 3, Chemical Composition of Larvae, Pupae, and Adults, by J. G. Haub and F. A. Hitchcock (pp. 32-37).

**The carrot rust fly (*Psila rosae* Fabr.),** A. J. HANSON and R. L. WEBSTER (*Washington Sta. Bul.* 405 (1941), pp. 24, figs. 10).—This pest was first recorded in Washington in 1908 but did not cause serious damage until 1928. It appar-

ently has a rather wide distribution in the Pacific Northwest. Important cultivated hosts are carrots, parsnips, celery, and parsley. Damage to these is caused by larvae feeding upon the root system. Larvae or puparia overwinter in the soil, and adults emerge during April, May, and June. The adults mate, and females deposit eggs near the base of plants. Eggs pass through an incubation period of 4 to 7 days. Larvae feed for about 30 days and transform to pupae during July. Adults of these appear about July 15. Second-brood larvae occur in late August and early September. Winter mortality reduces the population so that damage from spring-brood larvae is usually slight. If planting is deferred until late May or early June less damage occurs. Crude naphthalene flakes was the only satisfactory insecticide tested.

**Preliminary experiments on the control of the holly leaf miner, A. HARTZELL and G. F. McKENNA** (*Contrib. Boyce Thompson Inst.*, 12 (1941), No. 2, pp. 119-126, fig. 1).—Tests of a series of sprays and dusts for their efficiency in the control of the holly leaf miner, the most serious insect pest of holly in eastern North America, are reported. A spray consisting of 2 qt. of fish oil and 1 qt. of nicotine sulfate made up to 100 gal. with water sprayed on the foliage gave a reduction in mines of 91 percent in field plats at Yonkers, N. Y., as compared with the unsprayed check. Spray applications were made the second and third weeks in May, followed by an application about the middle of June and a final application around the middle of July.

**Notes on two genera of American flies of the family Trypetidae, J. R. MALLOCH** (*U. S. Nat. Mus. Proc.*, 92 (1942), No. 3133, pp. 20, fig. 1).—Notes are presented on 24 species of the genus *Trypanea*, 6 of which are described as new, and on 2 species of the genus *Neaspilota*. Keys for the separation of the species are included. The known records of the food habits of the larvae are included.

**Three new Dufourea bees from California (Hymenoptera: Apoidea), P. H. TIMBERLAKE** (Calif. Citrus Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 1, pp. 38-42).

**A monograph of the genus Chyphotes (Hymenoptera: Mutillidae: Apterogyninae) of North America, A. W. BUZICKY** (Minn. Expt. Sta.). (*Ent. Amer.*, 21 (1941), No. 4, pp. 201-243, figs. 13).—Of the 26 species of the mutillid genus *Chyphotes* recorded, 12 are described as new.

**Podagrion mantis Ashmead and other parasites of praying mantid egg cases (Hym.: Chalcidoidea; Dipt.: Chloropidae), O. P. BRELAND** (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 1, pp. 99-113).—Biological data are presented for four species of mantid egg parasites, namely, *P. mantis*, *Eupelmus coccidis* Gir., *Anastatus reduvii* (How.), and *Pseudogaurax signata* (Lw.), as observed in the vicinity of Austin, Tex., during the fall and winter of 1938-39 and 1939-40. All of these insects were reared from the egg cases of the Carolina mantis. *P. mantis* is a true external parasite of the individual mantid egg, and this is probably true for *E. coccidis*. *A. reduvii*, however, is an internal parasite, and all stages are passed within the mantid egg.

**A new chalcidoid parasite of the vetch bruchid, A. B. GAHAN** (U. S. D. A.). (*Ent. Soc. Wash. Proc.*, 44 (1942), No. 1, pp. 8-10).—Under the name *Tetrastichus bruchivorus* description is given of a new chalcidoid parasite of the vetch bruchid. It was reared from weevil-infested vetch collected in the Department of Var, France; from *Bruchus ulicis* M. & R. in the same French department; at quarantine in Philadelphia in seeds of vetch originating in Italy that were infested with *B. ulicis*; and from the vetch weevil collected at Statesville, N. C.

**The life cycle of Apanteles carpatus (Say) (Hymenoptera: Braconidae), a parasite of the webbing clothes moth (Tineola bisselliella Hum.),**

A. M. FALLIS (*Canad. Jour. Res.*, 20 (1942), No. 1, Sect. D, pp. 13-19, figs. 17).—Observations on the life history and habits of *A. carpatus*, a parasite of the larvae of the webbing clothes moth, are reported. Oviposition occurred and parasites developed in host larvae weighing from 1.6 to 6.8 mg. The parasites oviposited more readily in a host enclosed in a case, especially if the case contained fecal pellets of the host. Eggs were deposited in various parts of the host. A single parasite developed to maturity even though several eggs may have been deposited in the host, each by a separate "thrust" of the ovipositor. The rate of development was found to vary even at constant temperature. The average length of the life cycle at 27° C. was 26 days, but at 20° it required several months. Experiments were carried out to determine the factors responsible for the variation in the rate of development. The parasite larva upon emerging from the host usually spins a white silken cocoon, although metamorphosis was sometimes completed even though no cocoon was produced.

Observations on certain lepidopterous and hymenopterous parasites of *Polistes* wasps, P. RAU (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 2, pp. 355-366).—Following a recital of records (1) of lepidopterous parasites, (2) of moths known to prey upon *Polistes* wasps, and (3) of moths whose habits resemble those of *Dicymolomia pegasalis* Wlk., observations of the life histories of the pyralid moths *D. pegasalis* and *Chalcoela iphitalis*, new records of hymenopterous parasites, and records for 1939 are reported. The caterpillars of both *D. pegasalis* and *C. iphitalis* feed on the larvae of *Polistes* wasps, the former on three species and the latter on two species.

A new species of hymenopterous parasite of the pea aphid (*Macrosiphum pisi* Kalténbach), C. F. SMITH. (Univ. N. C.). (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 3, pp. 537-538).—Under the name *Aphidius pisivorus* a parasite reared from the pea aphid from many localities in Utah is described as new.

On the taxonomic status of *Gilpinia polytoma* (Htg.) and *G. hercyniae* (Htg.) (Hymenoptera: Diprionidae), W. A. REEKS (*Canad. Ent.*, 73 (1941), No. 10, pp. 177-188, figs. 44).—Studies conducted with the view to establishing the correct nomenclature and provide adequate descriptions of the two species of sawflies which hitherto have been included under the name *G. (Lophyrus, Diprion) polytoma* (Htg.) 1834 are reported. It is shown that *G. hercyniae* (Htg.) 1837 is the form which has been introduced into North America and has seriously injured spruce forests in northern New England and eastern Canada. *G. polytoma* is arrhenotokous (facultative parthenogenesis) and is known only from Europe, while *G. hercyniae* is thelytokous (obligatory parthenogenesis) and occurs in Europe and America. The distribution in Canada includes the provinces of Ontario, Quebec, New Brunswick, Nova Scotia, and Prince Edward Island. In the United States it occurs in Maine, New Hampshire, Vermont, Massachusetts, Connecticut, and New York.

Separation of the European spruce sawfly in America from *Gilpinia polytoma* (Htg.) (Diprionidae: Hymenoptera) and evidence of its introduction, R. E. BALCH, W. A. REEKS, and S. G. SMITH (*Canad. Ent.*, 73 (1941), No. 11, pp. 198-203).—In reporting further (see above) it is pointed out that the so-called European spruce sawfly which was discovered in Canada in 1930 and has been known as *G. polytoma* represents another species (*G. hercyniae*).

Of the two distinct species of spruce sawfly which occur in Europe hitherto included under the name *G. polytoma*, one (*G. hercyniae*) has the thelytokous method of reproduction, with a tendency to frequent and sustained diapause and a habit of spinning its cocoon in the forest floor. The female has 14 chromosomes, the male 7, and they can both be distinguished almost invariably from the other species by characters in the genitalia although no other morphological characters

are reliable. The other species (*G. polytoma*) has the arrhenotokous type of reproduction, with little or no tendency to diapause and a habit of spinning most of its cocoons above ground. The male has 6 chromosomes, the female 12. The spruce sawfly in Canada is identical with the European thelytokous species and appears to have been introduced from Europe. This conclusion regarding introduction is based on the brevity of its recorded history on this continent, on its distribution and the spread of the outbreak, on the almost complete failure of native parasites to attack it, and on the fact that a closely related bisexual form from which it is likely to have derived, or which originated from a common progenitor, exists in Europe but not in America.

**The diapause and related phenomena in *Gilpinia polytoma* Hartig), III-V, M. L. PREBBLE (*Canad. Jour. Res.*, 19 (1941), Nos. 11, Sect. D, pp. 350-362, figs. 5; 12, Sect. D, pp. 417-454, fig. 1).**—Further contributions are presented (*E. S. R.*, 86, p. 364).

**III. Bioclimatic relations (pp. 350-362).**—Description is given of the progress of intracocoon development in relation to temperature and moisture for a one-generation and a two-generation area of the European spruce sawfly in eastern Canada (= *G. hercyniae*; see article by Reeks above). In the one-generation area (central Gaspé) the degree of seasonal emergence from the overwintered cocoons can be forecast with considerable accuracy by means of sample analyses during the period of pronymphal and early pupal development. This is possible since few individuals that have not initiated development by late June do so later in the summer even though environmental conditions are quite favorable. The technic fails in a two-generation area (south-central New Brunswick) because members of the overwintered population may continue to respond to favorable temperature and moisture conditions throughout the entire season.

On the basis of biologic and climatic data the area occupied by the European spruce sawfly in eastern North America is divided into zones representing the probable distribution of one-, two-, and three-generation areas. Intermediate transitional zones are also indicated.

**IV. Influence of food and diapause upon reproductive capacity (pp. 417-436).**—In this work methods of sampling, determination of reproductive capacity, and analysis of data are considered. Various physical measurements are positively correlated with reproductive capacity, but regression equations are unsatisfactory for estimation of fecundity outside of the population in which the relationships have been determined, due to variability in the degree of joint variation of size and fecundity under different feeding conditions. Field populations developed on white spruce are more fecund than those developed on black spruce; reductions of 30 percent or more may result from periodic food shortage.

Reproductive capacity of females emerging over a period of 3 to 5 yr. in each of 20 populations failed to show any consistent trend in relation to the diapause period. From this and also from the slight reduction in eonymphal dry weight over extended intervals at favorable temperature it is concluded that the destruction of eonymphal reserves during diapause proceeds very slowly and has no practical effect upon fecundity of females issuing after prolonged diapause.

**V. Diapause in relation to epidemiology (pp. 437-454).**—This final paper in the studies on diapause in the spruce sawfly describes the direct and indirect influences of diapause on epidemiology in different parts of the distribution range in eastern North America. These relate to duration of diapause, degree of diapause in overwintered cocoons, and proportions of the population surviving to participate in the continuation of the infestation. The nature of infestations in different areas is described briefly.

A discussion of features of intraspecific differences and a summary of conclusions derived from all five papers in the series are also included.

***Ornithodoros parkeri* and relapsing fever spirochetes in Utah**, G. E. DAVIS (*Pub. Health Rpts. [U. S.]*, 56 (1941), No. 52, pp. 2464-2468, fig. 1).—Of 49 lots of ticks, ranging from 1 to 59 specimens (total 306), and collected in 16 counties of Utah, all but 1 were *O. parkeri*. A single specimen collected in San Juan County was *O. turicata*, this being the first record of its occurrence in Utah. Of 235 ticks that survived for testing, spirochetes were recovered from 7 lots from 4 counties, based upon a single test feeding upon white mice. Two cases of relapsing fever have been reported in Utah, one in 1923 and the other in 1930.

**A note on the bionomics of *Ixodes ricinus* L.**, M. L. BINGHAM (*Parasitology*, 33 (1941), No. 3, pp. 316-319).—In observations on the life cycle of the castor-bean tick some larvae were found to undergo a prolonged metamorphosis into nymphs in periods of 341, 354, and 361 days between the start of larval engorgement and nymphal emergence.

**Two new species of ticks from British Columbia (Ixodidae)**, J. D. GREGGON (*Canad. Ent.*, 73 (1941), No. 12, pp. 220-228, pls. 2, figs. 2).—Two ticks of the genus *Ixodes*, *I. hearlei* from the interior red squirrel (*Tamiasciurus hudsonicus streator*) and *I. ochotonae* from *Ochotona princeps* ssp., *Peromyscus* sp., and *Neotoma cinerea* ssp., are described from British Columbia.

**Effect of length of day on the activity and hibernation of the American dog tick (*Dermacentor variabilis* (Say))** (Acarina: Ixodidae), C. N. SMITH and M. M. COLE (U. S. D. A.). (*Ann. Ent. Soc. Amer.*, 34 (1941), No. 2, pp. 426-431).—The length of day is an important factor in controlling the activity or hibernation of larvae and nymphs of the American dog tick. Long photoperiods are more favorable to activity than short ones and gradually increasing photoperiods more favorable than gradually decreasing ones of even greater absolute length.

**The transmission of *Theileria parva* by ticks**, E. A. LEWIS and W. FOTHERINGHAM (*Parasitology*, 33 (1941), No. 3, pp. 251-277, figs. 19).—Report is made of experiments conducted in continuation of those previously noted (E. S. R., 78, p. 696) which deal with the effect of low temperature on the development of *T. parva* in engorged larvae of *Rhipicephalus appendiculatus*. Reference is made to records of mild reactions to East Coast fever when the parasites are either rare or absent, and instances are given of such reactions followed by recovery in experimental animals. Although the mild form of the disease seems associated at times with light tick infestation, it is proved that a few infected ticks also transmit a fatal East Coast fever. It is shown also that ticks fed on a bovine during a short or mild reaction can produce a virulent form of the disease in susceptible animals, and that mild reactors acquire an immunity to the virulent disease. The experiments indicate that ticks do not become infected with *T. parva* from the blood of a bovine for the first 4 days of the reaction period. Evidence is produced which strongly suggests that *T. parva* tends to disappear from infected hungry ticks kept under laboratory conditions for about a year or more. The age of the tick would appear to be an important factor in the transmission of East Coast fever. Attempts to break down the immunity to East Coast fever and to produce "turning-sickness" by massive infestations of ticks were unsuccessful, and further experiments on the transmission of East Coast fever by ticks which had fed on animals suffering from turning-sickness did not confirm earlier positive results.

**The differentiation of the eggs of the trichostrongylid species *Nematodirus filicollis* and *N. spathiger***, J. H. TETLEY (*Jour. Parasitol.*, 27 (1941), No. 6, pp. 473-480, figs. 5).

## ANIMAL PRODUCTION

**Temperature factors in animal production, S. BODY.** (Univ. Mo.). (*In Temperature—Its Measurement and Control in Science and Industry. New York: Reinhold Pub. Corp., 1941, pp. 462-473, figs. 10*).—The influence of environmental conditions and sweating on heat production by several classes of animals is discussed.

[**Experiments with cattle, sheep, and swine by the Georgia Station**] (*Georgia Sta. Rpt. 1941, pp. 70-77, 78, 90-98, 109, figs. 2*).—Results are presented on studies of the effect on gains and quality and grade of carcass of steers of supplements of peanut meal to pasture and of sorghum silage, ground and whole peanut hay, lespedeza hay, cottonseed hulls, peanuts and vines, and potato meal when fed with corn and cottonseed meal rations; cottonseed meal, peanut meal, lespedeza hay, peanut hay, oat straw, and silage for wintering beef cattle; creep feeding calves; sweetpotatoes and vines stored in pit silos; relation of temperature and the breed of ram to breeding of ewes; peanuts, peanut meal, and hay from vines for pork production; production of total digestible nutrients and gains from fertilized and unfertilized pastures; and comparison of clovers and carpet-grass for pasturing steers at Jonesboro.

**The feeding of livestock, H. E. WOODMAN** (*Jour. Roy. Agr. Soc. England, 102 (1941), pp. 66-81*).—A summary of nutrition of cattle, poultry, sheep, swine, and horses is given, together with a description of the nutritive value and composition of byproducts of pea canning.

**Feeding dried nettles to livestock, W. KING WILSON** (*Nature [London], 147 (1941), No. 3739, pp. 796-798*).—Results are reported of a study in which the hay cut from poultry pens and fed to one group of 10 rabbits was replaced in another lot of 10 animals with nettles cut and dried for from 3 to 4 weeks. The group receiving the nettles, although limited to the same feed consumption as the hay-fed group, made 17 percent greater gain during an 8-week feeding period than the controls. The nettles when cut and dried proved to be a satisfactory and palatable substitute for the hay.

[**Pasture comparisons with pigs and cattle at the Delta substation**] (*Miss. Farm Res. [Mississippi Sta.], 4 (1941), No. 12, p. 5*).—Although a ration of 70 parts corn meal and 30 parts cottonseed meal produced cheaper gains in pigs with soybean pasture than a ration of corn meal 85 parts, cottonseed meal 7.5, and tankage 7.5, the finish of the pigs was not quite equivalent to pigs on the standard ration. Some stiffness developed in pigs on the oat pasture with different amounts of cottonseed meal as a protein supplement, but there was no correlation with the amount of cottonseed meal fed since stiffness was least prevalent in the lots receiving the most and the least cottonseed meal. The largest gains were made by pigs receiving a ration of 85 parts corn and 15 parts cottonseed meal. The best finish was produced on the oat pasture and corn without protein supplement, but such pigs did not have a well developed bone and frame, and larger amounts of feed were required than when a protein supplement was fed. Dallis grass and white dutch clover appeared to furnish the most palatable grazing for the greatest number of days for cattle of any of several permanent pasture grasses.

**Crotalaria for forage.** (Coop. U. S. D. A.). (*Florida Sta. Bul. 361 (1941), pp. 72, figs. 17*).—This is a comprehensive review of the production of and value of crotalaria as a feed for livestock.

In part 1, on Production of *Crotalaria* for Forage, by G. E. Ritchey and R. McKee, 11 species of *Crotalaria* used in the investigation are described. Pasture studies with dairy cows showed that *C. incana* planted in rows was grazed most

consistently early in the season, but later became woody, though making good recovery from grazing. *C. intermedia*, which ranked second in palatability and appeared less fibrous, was preferred as a pasture crop because of its abundant foliage and ability to hold leaves until reasonably late in the season. Cultural studies of seeding methods of *C. intermedia* showed that the finest quality of forage was obtained from seedlings of 5-7 lb. per acre in 3-ft. drills. Natural curing produced a coarse, stemmy, woody hay, but the quality was improved by cutting and curing in an artificial drier. In comparative tests of different species of *Crotalaria* for silage the highest yields in 1932 were obtained from *C. spectabilis* and by *C. goreensis* in 1933. The maximum yield of *C. intermedia* desired for silage was produced by harvesting in the bud stage.

Part 2, by R. B. Becker, W. M. Neal, and P. T. Dix Arnold, discusses the value of *crotalaria* as feed. In palatability trials by dairy cows in grazing the more tender forage was preferred. In palatability studies of hay, dairy cattle showed preference to soybeans over species of *Crotalaria*. *C. intermedia*, *C. incana*, and *C. lanceolata* ranked in that order in free choice consumption from racks in 1931, 1932, and 1933. Considering preferences for silages, *C. intermedia* ranked well in the different years. In the prebud stage the fiber content was in the range with common hay crops (27-33 percent), but at later stages more fiber was present. Details of digestion trials with *C. intermedia* hay and silage previously reported (E. S. R., 74, p. 81) are discussed. Feeding and grazing studies were carried on also with mules. Some toxicity to cattle, mules, swine, fowls, and game birds from *C. spectabilis* was found due to the presence of an alkaloid—"monocrotaline." These findings indicate that neither the green forage, hay, or silage of *C. spectabilis* should be offered to livestock.

Destruction of carotene and vitamin A by certain feeds, G. S. FRAPS, W. W. MEINKE, R. REISER, and A. R. KEMMERER. (Tex. Expt. Sta.). (*Food*, 10 (1941), No. 117, p. 196).—A survey showed some feeds had the power of destroying carotene in dry contact while others did not. Autoclaving meat scraps removed the carotene-destroying power.

Inspection of commercial feedstuffs, P. H. SMITH (*Massachusetts Sta. Control Ser. Bul.* 110 (1941), pp. 64).—The usual compilation (E. S. R., 84, p. 798) is given of the guaranteed and found analyses of 1,744 feed samples officially examined in Massachusetts up to September 1, 1941, together with analyses of 12 samples of vitamin D feeds and 9 samples of feeding molasses.

The use of nitrite in meat preservation, T. M. FERNANDEZ (*Philippine Jour. Anim. Indus.*, 8 (1941), No. 4, pp. 371-380, figs. 3).—Within 15 days there was almost complete penetration of hams, bacon, and tongues by sodium nitrite, and it is recommended that sodium nitrite be used in place of potassium nitrite in sweet-pickle- and dry-cured hams and bacons.

[Sheep breeding at the Delta substation] (*Miss. Farm Res. [Mississippi Sta.]*, 4 (1941), No. 12, p. 5).—Topcrossing native and mixed ewes with Hampshire rams increased wool production.

Chemical composition of the bones of sheep in Western Australia, E. J. UNDERWOOD (*Austral. Jour. Expt. Biol. and Med. Sci.*, 18 (1940), No. 4, pp. 405-408).—The calcium, phosphorus, and nitrogen analyses of the long bones of ewes (2.5 to 3 yr. of age) which had been grazing on dry feed were not significantly different from the long bones of ewes grazing on the same feed with phosphorus supplements. Analyses are presented for the long bones of eight ewes on the dry feed and three with a phosphorus supplement and of the humerus, femur, certain ribs, and vertebrae of wethers on dry feed.

Trends in mohair production in Texas, J. M. JONES. (Tex. Expt. Sta.). (*Southwest. Sheep and Goat Raiser*, 11 (1941), No. 11, pp. 10, 35, 36, 37, 39).—

A popular account is given of estimates in mohair production in seven Western States in 1940.

**The potassium requirements of growing pigs,** E. H. HUGHES and N. R. ITTNER. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 3, pp. 189-192, fig. 1).—Since pigs appeared to need K for optimum growth, the purified ration employed in the previous study was supplemented with 0, 2.25, 4.5, and 9.5 gm. of KCl per 100 lb. live weight to indicate the amounts of K required. The results with lots of five pigs each showed that without K supplement the pigs gained slightly and then lost weight after about 4 weeks and generally finally died. The pigs on rations supplemented with 1.18 gm. (2.25 gm. KCl) per 100 lb. of pig gained but the growth rate was less than when 4.5 gm. of K were supplied per day per 100 lb. live weight. It was then considered that 0.08 percent K was not sufficient and 0.15 percent K in the ration was near the requirement.

**Pantothenic acid in the nutrition of the pig,** E. H. HUGHES. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 3, pp. 185-187, figs. 2).—Pantothenic acid seems necessary for normal growth and well-being in the growing pig. In two experiments, two and five pigs, respectively, on rations lacking pantothenic acid showed an early decrease in appetite, slow growth, and an inability to move about in a normal manner in about 1 mo. With additions of 6.8 mg. of pantothenic acid per 100 lb. of live weight, daily gains of 0.82 and 0.74 lb. were made in the two experiments. Autopsies of the pigs on the deficient rations showed gastritis and inflammation in the large intestine.

**The body fats of the pig.—V, Component glycerides of perinephric and outer back fats from the same animal,** T. P. HILDTCH and W. H. PEDELTY (*Biochem. Jour.*, 34 (1940), No. 7, pp. 971-979).—Continuing this series,<sup>5</sup> previously noted in part (E. S. R., 68, p. 800), the authors found that a chemical analysis of the approximate proportions of the groups of glycerides in back and kidney fat samples supports the hypothesis that steatoglycerides in the animal storage fats resulted from the saturation of preformed oleoglycerides. Concurrently the observations disclose a subordinate effect not connected with a hydrogenation mechanism, namely, a gradual increase in the proportions of dipalmitoglycerides as the general degree of saturation of the depot fats becomes more pronounced.

**Hog carcass studies: Effect of early rate of growth on leanness of carcass,** E. W. CREAMPTON (*Sci. Agr.*, 20 (1940), No. 10, pp. 592-595).—No significant relationships were found in 247 pig carcasses between the rate of gain in live weight and either the length or leanness of the bacon carcass produced. There were differences in rates of gain per day of more than 0.25 lb. and of more than 0.75 lb. in feed intake between the slowest- and fastest-gaining sixths of the population. The data analyzed by variance and covariance do not substantiate the conclusions of McMeekan (E. S. R., 81, p. 403).

**A preliminary report on a new system for the identification of horses,** J. A. SOLIS (*Philippine Jour. Anim. Indus.*, 8 (1941), No. 4, pp. 345-351, pls. 3).—Methods are described for the identification of horses by taking gutta-percha or photographic prints of the anterior third of the hard palate.

**Practical dog feeding,** C. J. KOEHN (*Alabama Sta. Bull.* 251 (1942), pp. [1]+23).—The nutritional requirements of the dog, types of diet, recommended home-mixed rations, and the feeding of pups are dealt with in this practical account. The Alabama standard for canned dog food adopted July 18, 1938, is given in the first of two appendixes and the following tables: (1) Chemical composition of recommended rations tabulated by ingredients to show the sources of

<sup>5</sup> *Biochem. Jour.*, 29 (1935), No. 1, pp. 90-99, fig. 1.

protein, fat, carbohydrate, fiber, calcium, and phosphorus; (2) comparison by age, of body weight and of feed consumed daily by fox hounds receiving dry rations and a good brand of canned dog food; (3) percentage chemical composition of commercial canned dog foods; and (4) formulas which have been tested and found to be unsatisfactory for home-mixed rations are found in the second appendix.

**The hatchability of chicken eggs as influenced by environment and heredity**, W. LANDAUER ([*Connecticut*] *Storrs Sta. Bul.* 236 (1941), pp. 124, figs. 30).—This is a revision of Bulletin 216 (E. S. R., 77, p. 837), summarizing studies on hatchability conducted at the station and other institutions.

**The effect of incubation on the vitamin content of eggs**, E. E. SNELL and E. QUARLES (*Jour. Nutr.*, 22 (1941) No. 5, pp. 483-489).—Microbiologic assays by the methods of Snell et al. (E. S. R., 85, p. 442) of the vitamin components of eggs at different stages of incubation and after hatching showed that the pantothenic acid and riboflavin contents remained essentially the same, whereas biotin decreased from an average around 68 mγ to about 25 mγ per gram during incubation. Nicotinic acid and inositol are apparently synthesized. Over 20 times the amount of nicotinic acid in the unincubated egg was found in the newly hatched chick. The newly hatched chick contained over 6 times as much inositol as the unincubated egg. It thus appears that the chick does not need nicotinic acid and inositol, but it is not evident if enough is synthesized for optimum growth.

**A comparison of wet and dry cooling of dressed poultry**, J. ROBERTS and E. I. ROBERTSON (*Washington Sta. Bul.* 403 (1941), pp. 15, figs. 7).—The wet-cooled birds gained weight, and the dry-cooled lost. The wet method cooled more rapidly, and the poultry presented a better appearance and were equal or superior in flavor to the dry-cooled birds. The higher scalding temperatures resulted in the greater weight changes and more discoloration. Discoloration was retarded by plumping, whereas wet cooling prevented discoloration. The appearance of dry-picked poultry was not affected by the method of cooling, and its weight change was less than that of the scalded birds.

**Concentrate feeding of turkeys**, E. I. ROBERTSON and J. S. CARVER (*Washington Sta. Bul.* 402 (1941), pp. 16, figs. 3).—High-protein concentrate mixtures containing 39 percent of protein feed with alfalfa range and whole corn, oats, wheat, and barley free choice produced greater weight in broad-breasted Bronze tom and hen turkeys up to 28 weeks of age than was produced by similar groups under confined conditions with a developing mash containing about 20 percent of protein and with a mixture of whole grains. Hens and toms grew similarly and were approximately equal in efficiency of feed utilization up to 16 weeks of age. After this age, the toms continued to grow at about the same rate, while the hens showed a perceptibly slower growth rate.

## DAIRY FARMING—DAIRYING

**Dairy research in the defense effort** (*U. S. Dept. Agr., Sec. Agr. Rpt.*, 1941, pp. 117-120).—Included are brief progress reports of studies on the economic limits in the feeding of extra grain to milking cows (coop. 10 State experiment stations), the ovarian-stimulating action of certain young plant materials and the role of pastures in improving the reproductive function of cows, mammary development in young heifers as a basis for predicting future producing ability, the production of vitamin B<sub>2</sub> concentrate from cheese whey, a method for increasing the solids content of evaporated milk without curdling in the heat of sterilization, and the development of processes for making lacquers and resins

from lactic acid suitable as a protective coating for milk cans and other dairy utensils.

[**Dairy investigations in Georgia**] (*Georgia Sta. Rpt. 1941, pp. 69, 89-90, 98-99*).—Progress reports are presented for the following studies: A comparison of sweetpotato meal and peanuts on the vine as a milk-producing feed for dairy cattle, the effects on growth and development of supplementary concentrate feeding for heifers on summer pasture, and the returns secured from improved dairy pastures.

[**Experiments with dairy cattle and dairy products in Wisconsin**] (*Wisconsin Sta. Bul. 453 (1941), pp. 12-18, 66-72, figs. 5*).—From a series of studies on the role of vitamins in dairy cattle nutrition by P. Phillips, N. Lundquist, P. Boyer, I. W. Rupel, and H. Lardy, results are noted on the control of calf scours by feeding adequate amounts of vitamins A and B, the vitamin A requirements of calves, the relation of vitamin A intake to the concentration of plasma ascorbic acid and, in turn, to the breeding efficiency of dairy cattle, the value of shark-liver oil as a source of vitamin A for dairy cattle, and the possible role of manganese in the synthesis of vitamin C by animals.

Reports of other nutrition investigations by Rupel, G. Bohstedt, E. B. Hart, M. I. Wegner, A. N. Booth, and C. A. Elvehjem include the utilization of urea as a source of nitrogen by ruminants and the effect of the level of protein in the ration on the utilization of urea, and the synthesis of various members of the vitamin B complex in the alimentary tract of dairy heifers.

From dairy products investigations by F. M. Skelton, H. H. Sommer, J. W. Knechtges, W. Price, and W. Langhus, results are noted on factors affecting the viscosity of cream, the utilization of corn sirup in the manufacture of ice cream, methods of packaging natural cheese, the optimum time for salting brick cheese, and the role of surface microflora in the ripening of brick cheese.

**Dairy cattle: Selection, feeding, and management**, W. W. YAPP and W. B. NEVENS (*New York: John Wiley & Sons; London: Chapman & Hall, 1941, 3. ed., pp. XVIII+456, pls. [10], figs. 146*).—The third edition of this well-known textbook is noted (*E. S. R.*, 63, p. 889).

**Experiments with annual crops and permanent pastures to provide grazing for dairy cows in the Sandhill region of the Southeast**, E. W. FAIRES, J. R. DAWSON, J. P. LAMASTER, and G. H. WISE. (*Coop. S. C. Expt. Sta.*). (*U. S. Dept. Agr., Tech. Bul. 805 (1941), pp. 42, figs. 6*).—Grazing experiments were conducted with dairy cattle over a 5-yr. period on eight 2-acre plats seeded to annual crops to determine the possibility of providing year-round pasturage under conditions prevailing in the Sandhill region. The two major crops were (1) a combination of oats, barley, rye, and vetch for winter and early-spring grazing, and (2) a combination of soybeans and pearl millet for summer and early-fall grazing. Three other crops, included as trial crops, were (1) corn interplanted with velvetbeans for fall grazing, (2) crimson clover and Italian ryegrass for spring grazing, and (3) pearl millet for summer grazing. During the experimental grazing, cattle were rotated from one plat to another as frequently as was considered necessary to obtain optimum yields. In conjunction with the annual grazing crops, records were kept on the cost and carrying capacity of a permanent pasture established on similar land. Yields of all crops were established by harvesting representative protected areas as well as by grazing.

The yields, and distribution of the yields, varied widely from year to year, depending largely on the amount and distribution of rainfall. The combination of oats, barley, rye, and vetch, the pearl millet, and the corn and velvetbeans produced the best results in terms of total yields and distribution

of yields. The average number of grazing days per season and the estimated cost per 100 lb. of total digestible nutrients were—permanent pasture 152 days and 82 ct.; pearl millet 109 and \$1.18; soybeans and pearl millet 114 and \$1.93; oats, barley, rye, and vetch 99 and \$3.23; Italian ryegrass and crimson clover 24 and \$6.55; and corn stover and velvetbeans 70 days and \$1.77.

**Die Einsäuerung jungen, eiweissreichen Grünfutters mit Trockenmolke** [Ensiling young protein-rich green fodder with dried whey], G. RUSCHMANN and H. BÄRTRAM (*Zentbl. Bakt. [etc.]*, 2. Abt., 103 (1941), No. 12-14, pp. 193-224, figs. 7).—Dried whey was added to green alfalfa and to a grass mixture at rates of 0, 1.68, 3.36, and 5.04 percent at the time of ensiling. Extensive data are presented on the chemical and bacteriological properties of the resulting silages. The optimum level of dried whey as a preservative appeared to fall between 2 and 3 percent. The importance of the microflora of the dried whey in affecting the fermentation process in the silage is stressed. A comparison of dried whey and pure lactose as preservatives indicated that compounds in whey other than the milk sugar exerted a beneficial effect on the silage. The buffer properties of the silage apparently were improved by the proteins and minerals contained in the dried whey.

**Studies on the secretion of milk fat.—III, The effect of thyroxine administration on the blood lipoids and on the nature of the milk fat**, J. A. B. SMITH and N. N. DASTUR (*Biochem. Jour.*, 34 (1940), No. 7, pp. 1093-1107, figs. 6).—Continuing this series (*E. S. R.*, 81, p. 267), thyroxine was administered by intramuscular injection to four lactating cows at the rate of 10 mg. daily over 10- to 15-day experimental periods. Yields of milk and fat were markedly increased during the injection period, but no consistent changes in the level of nonfatty solids in the milk occurred other than a slight decrease in protein concentration. Also, the nature of the milk fat was not significantly altered except for a slight temporary change at the beginning of the hyperthyroid period. The concentration of plasma sugar was increased from 10 to 26 percent, accompanied by a decrease of from 10 to 20 percent in the concentration of the main lipid constituents in the plasma during the injection period. The relationship between the plasma lipoids and yield of milk fat is briefly discussed.

**Secretion of orally administered radio-iron in the milk of cows**, L. A. ERF. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 46 (1941), No. 2, pp. 284-287).—Immediately after complete milking, two cows (one Holstein and one Jersey) were drenched with 155 cc. of iron chloride solution, each cubic centimeter of which contained 4 mg. of  $\text{FeCl}_3$  (radio-iron). Six hr. later both cows were milked and bled, and milking occurred twice daily thereafter for 3 days. The milk secreted by the Holstein and Jersey, respectively, over the 78-hr. period contained 0.121 and 0.128 percent of radio-iron per liter, equivalent to 1.5 and 2.5 percent of the orally administered iron.

**Observations on the serum phosphatase of cattle and sheep**, W. M. ALLCROFT and S. J. FOLLEY (*Biochem. Jour.*, 35 (1941), No. 3, pp. 254-266).—Phosphatase values as determined in 367 blood samples from dairy cows, 119 from beef cattle, and 555 from ewes are summarized. In apparently normal animals these serum phosphatase values ranged from 0.3 to 114.3 and 3.0 to 166.1 units per 100 cc., with 71.2 and 53.3 percent containing less than 15 units and 90.7 and 91.7 percent less than 40 units for cows and ewes, respectively. In view of these wide fluctuations it is concluded that serum phosphatase determination can be of little diagnostic value. Despite wide differences between animals, the general level of an individual tended to remain rather constant over long periods. In both cattle and sheep, serum phosphatase

values progressively decreased with advancing age to maturity and was relatively stable thereafter. There is some evidence that pregnancy per se is accompanied by a slightly raised serum phosphatase in dairy cows, though the level of phosphatase does not appear to be correlated with the stage of pregnancy. No evidence was found of correlation between milking capacity and serum phosphatase activity in dairy cows. The high phosphatase activity of the sera of some clinically healthy cows does not appear to be due to an enzyme activator in these sera.

**Growth response of thyroidectomized goats to artificially formed thyroprotein,** E. P. REINEKE and C. W. TURNER. (Mo. Expt. Sta.). (*Endocrinology*, 29 (1941), No. 5, pp. 667-673, figs. 2).—Following an operative technic as described, a number of goat kids were thyroidectomized during the first month of life. Approximately 1 mo. later, after symptoms of thyroid deficiency had developed, three pairs of the thyroidectomized kids, respectively, received orally 0.3, 0.5, and 1.0 gm. per head daily of thyrolactin-iodinated skim milk protein (E. S. R., 83, p. 608). This treatment arrested the development of cretinism and stimulated growth approaching that of the normal. Growth rate was roughly proportional to the amount of thyroprotein given within the range covered. It is concluded that the thyroprotein had a physiologic activity fully comparable to thyroid substance. The possible utilization of thyroprotein in animal production is discussed.

**Quantitative study of the effect of inanition on responsiveness of the mammary gland to estrogen,** J. J. TRENTIN and C. W. TURNER. (Mo. Expt. Sta.). (*Endocrinology*, 29 (1941), No. 6, pp. 984-989, fig. 1).—Groups of male albino mice, weighing from 15 to 20 gm. each, were fed at five levels of feed intake, i. e., 1.5, 2, 2.5, and 3 gm. and unlimited amounts per mouse daily. Oestrogen (oestradiol benzoate) was administered to members of the different groups in amounts ranging from 1 to 32 Lewis units (E. S. R., 82, p. 322). It was found that as the food intake level decreased the amount of oestradiol benzoate required to produce a minimum duct growth response of the mammary gland was greatly and proportionately increased.

**The assay of prolactin by means of the pigeon crop-gland response,** S. J. FOLLEY, F. J. DYER, and K. H. COWARD (*Jour. Endocrinol.*, 2 (1940), No. 2, pp. 179-193, figs. 6).—A summary of experiences with the crop-weight method for prolactin assays with pigeons showed that for assay of prolactin there should be from 15 to 20 pigeons between 260 and 360 gm. in live weight for each range in dose. The temperature should be maintained at 15° C. and results calculated on the basis of live weight. The relation between crop weight or ratio of crop weight to live weight and dose of hormone was best exhibited by a sigmoid curve.

**Further experiments on the continued treatment of lactating cows with anterior pituitary extracts,** S. J. FOLLEY and F. G. YOUNG (*Jour. Endocrinol.*, 2 (1940), No. 2, pp. 226-236, fig. 1).—Continuing this line of investigation (E. S. R., 80, p. 473; 83, p. 100), four groups of four cows each, all in declining stage of lactation, respectively, received repeated injections over 22 days of (1) inert protein in the form of thymus extract, (2) crude alkaline pituitary extract, (3) concentrated prolactin preparation, and (4) glycotropic preparation. The crude pituitary extract increased the average daily milk production during the experimental period to an average of 16 percent above the expected level, whereas the prolactin preparation, which was seven times as potent as the crude extract in pigeon crop-gland-stimulating activity, increased the milk yield only 5 percent above that expected. The glycotropic preparation had no apparent effect on production. None of the treatments involving pituitary

extract affected the fat content or nonfatty solids in the milk. The significance of these results with respect to a belief in the existence of a single milk-stimulating hormone secreted by the anterior pituitary gland is discussed.

**An analysis of the relationship between the curd tension and the curd surface area of milk,** A. B. STORRS (*Jour. Dairy Sci.*, 24 (1941), No. 12, pp. 1041-1046).—Continuing this line of investigation (E. S. R., 86, p. 378), curd tension and curd surface area were determined on sublots of untreated whole milk, homogenized milk, enzyme-treated milk, and base exchange milk, each adjusted to a pH of 4.0, 4.5, 5.0, 5.5, and 6.0. The coefficients of correlation between curd tension and curd surface area varied considerably, showing both positive and negative correlations, but in no instance were they of sufficient magnitude to be considered significant. It is concluded that curd tension and curd surface area are independent characteristics of milk and that each may be influenced or determined by factors not closely related.

**Studies on soft curd milk prepared by the enzyme treatment method,** A. W. TURNER. (Univ. Ill. et al.). (*Soc. Expt. Biol. and Med. Proc.*, 46 (1941), No. 4, pp. 593-595).—Enzyme treatment in these investigations consisted in adding 1 part of pancreatic concentrate of high tryptic value to 10,000-15,000 parts of cold raw milk, followed by pasteurization in the usual manner. From in vitro digestion experiments it was found that enzyme-milk filtrates contained an average of 18.1 percent more protein than normal milk filtrates. The enzyme-treated milk contained considerably more alcohol-soluble protein and proteose peptone nitrogen but only slightly more amino acid nitrogen than normal pasteurized milk. Casein prepared from enzyme-treated skim milk was more soluble in 70 percent alcohol than that prepared from pasteurized milk.

**Die Aromabildung bei der Rahmsäuerung [The development of aroma in the ripening of cream],** A. I. VIRTANEN, P. KONTIO, and T. STORGARDS (*Biochem. Ztschr.*, 307 (1941), No. 3, pp. 215-219).—To test the theory that acetylmethylcarbinol is formed from citric acid during the ripening of cream by aroma-producing bacteria, pure cultures of these organisms were grown on various media. Acetylmethylcarbinol was produced from glucose in the presence of methylene blue or quinone, but not in the absence of a suitable hydrogen acceptor. It was not formed from citric acid, even in the presence of methylene blue. Apparently sugar and not citric acid is the essential material in aroma development.

**What you can do with colloidal stabilizers,** W. C. COLE. (Univ. Calif.). (*Food Indus.*, 13 (1941), Nos. 9, pp. 44-48, figs. 3; 10, pp. 57-59, figs. 2).—The relation of colloidal stabilizers in food processing is discussed, with particular reference to those that stabilize (1) emulsions, (2) suspensions, (3) foams, (4) jellies as a result of gelation, and (5) the texture of frozen products such as ice cream and other frozen foods by retarding or preventing the growth of ice crystals. The necessity of selecting stabilizers particularly adapted to the system requiring stabilization and regulation of the processing to secure the desired results is stressed. A bibliography of 22 references is included.

**The whence and whither of milk sanitation,** R. S. BREED. (N. Y. State Expt. Sta.). (*Canad. Pub. Health Jour.*, 31 (1940), No. 9, pp. 414-423).—An interesting history of the development of the milk sanitation movement from 1880 to the present.

**The lethal effectiveness of ultra violet rays applied to milk,** G. C. SUPPLEE, G. E. FLANIGAN, and O. G. JENSEN (*Jour. Dairy Sci.*, 24 (1941), No. 12, pp. 1055-1070, figs. 10).—Various sources of ultraviolet radiation supplied by mercury arcs and both standard and special lamps were applied to both flowing and stationary films of milk in the series of tests described. Bacterial plate counts

on milk were made with tryptone glucose agar incubated at 37° C. The bactericidal effect from such radiation was greater when applied to a smooth-flowing milk film than to films flowing over a corrugated cooler surface. Also, the lethal radiation was relatively more effective per unit volume of milk when applied to flowing films than when applied to stationary films having a thickness of an adhesion layer only. The spectral characteristics of the radiation as well as the intensity greatly influenced its lethal effectiveness. Radiation predominantly in the 2,200 to 2,300 Å. region gave erratic bactericidal results, and in some cases sublethal doses appeared to cause stimulation. The total lethal effect of radiation and elevated temperatures when applied simultaneously for less than 1 sec. appeared to be an additive process. By applying ultraviolet radiation of appropriate intensity and spectral characteristics, at least 90 percent and frequently from 95 to 98 percent of the bacteria of raw milk could be regularly destroyed.

**"Quick-time" pasteurization of milk**, A. C. DAHLBERG, R. F. HOLLAND, and R. K. MINER (*New York State Sta. Tech. Bul.* 261 (1941), pp. 15).—Supplementing earlier laboratory trials (E. S. R., 84, p. 809), experiments were conducted on short-time high-temperature pasteurization of milk under controlled factory conditions. The pasteurizing equipment consisted of a section of 12 internal tubes 1.5 in. in diameter by 10 ft. in length. Preheating occurred in the first three tubes, maximum heating was reached in the fourth and fifth, and gradual cooling occurred in the remaining seven tubes. Milk was successfully quick-time pasteurized at 169° to 177.5° F., with a time interval above 140° ranging from 5 to 24 sec. At these higher temperatures the variation in the highest temperature attained could be greater than the present expected pasteurization standards and still show proper pasteurization. In general, milk subjected to quick-time pasteurization was slightly superior in quality to that pasteurized by the conventional vat-holder method.

**Detergents in the dairy industry**, C. SCHWARTZ (*Jour. Milk Technol.*, 4 (1941), No. 5, pp. 258-267, figs. 2).—This is a general discussion of the dairy equipment cleaning problem, with a classification of detergents and suggestions regarding the selection and use of a detergent best adapted to a particular job. As a general conclusion, it is stated that the best detergent available to the dairy industry today is one in which there is contained an efficient calcium-sequestering material for the control or prevention of alkaline-earth-metal precipitates, and an alkali sufficient in amount to do a good cleaning job and of a type least harmful both to operator and equipment.

**Factors affecting the gas content of milk**, C. I. NOLL and G. C. SUPPLEE (*Jour. Dairy Sci.*, 24 (1941), No. 12, pp. 993-1013, figs. 3).—Based on the analyses of 63 mixed raw milk samples as received at commercial milk plants, average gas contents were—oxygen 0.47 percent, nitrogen 1.29, and carbon dioxide 4.45 percent. The oxygen content of hot milk under short-time, high-temperature pasteurization was reduced approximately 50 percent, but substantial amounts of oxygen were reabsorbed during subsequent cooling, the final amount surpassing the prepasteurization level in some cases when a large surface per unit volume was exposed to air during cooling. The flushing of milk with air under 25-in. vacuum, with nitrogen at atmospheric pressure, and with either nitrogen or carbon dioxide under vacuum were all highly effective in removing oxygen from milk. The efficiency of any of the systems increased as milk temperatures were increased. It is shown that the effects of temperature and pressure on the gas content of milk followed the well-known physical laws governing the solubility of gases in liquids. Ascorbic acid proved to be very reactive, consuming oxygen dissolved in milk. It could be employed as a means of deoxygenating milk,

and conversely its stability or preservation was dependent upon the absence of dissolved oxygen in milk. In the absence of dissolved oxygen, ascorbic acid in milk proved stable to intense light, to the oxidizing effect of copper salts, and to high temperature.

**Oxidized flavor in milk.**—X, The effect of feeding potassium iodide supplements to dairy cows on the carotene content of the butter fat and on the ascorbic acid content of the milk and the relationship to metal-induced oxidized flavor, W. C. BROWN, A. H. VANLANDINGHAM, and C. E. WEAKLEY, JR. (W. Va. Expt. Sta.). (*Jour. Dairy Sci.*, 24 (1941), No. 12, pp. 1035-1039, figs. 2).—Continuing this series (E. S. R., 86, p. 523), five Jersey cows received, in addition to the regular herd ration, 5 gm. daily of potassium iodide over a 14-day period. Milk produced during that period was markedly lower in ascorbic acid content but essentially unchanged in carotene content or susceptibility to copper-induced oxidized flavor development as compared with milk produced during the 4 weeks preceding and the 2 weeks following the period of supplemental feeding. It is concluded that the level of the ascorbic acid in milk may not be so great a factor in determining susceptibility to oxidized flavor development as was formerly believed.

**Studies on the antioxygenic effect of oat flour treated milk bottles for milk exposed to sunlight,** C. W. ENGLAND and A. P. WIEDEMER. (Md. Expt. Sta.). (*Milk Dealer*, 31 (1941), No. 3, pp. 33-34, 36, fig. 1).—Mixed herd milk, handled without contact with copper but known to be susceptible to spontaneous oxidation, was used throughout the series of trials. Identical lots of pasteurized cooled milk were bottled in plain glass bottles, untreated paper bottles, and treated paper bottles (the treatment consisting of sizing cardboard with finely milled oat flour prior to fabrication and paraffining). Sublots of each were exposed at 40° and 70° F. to morning, midday, and afternoon sun for 10, 20, and 40 min., then held in the dark at 40°, and judged for flavor after 12, 24, and 48 hr.

In all cases intensity of oxidized flavor increased with increasing length of exposure, and this defect was more intense after exposure at 70° than at 40°. Midday sun activated greater intensity of off-flavor in glass bottles, while morning sunlight had greater effect on milk in paper bottles. Under like conditions, paper bottles afforded more protection to milk than glass bottles. The treated paper bottles afforded some protection to milk against oxidized flavor when the period of exposure to sunlight exceeded 10 min.

**Microbiology of paper containers,** J. R. SANBORN. (N. Y. State Expt. Sta.). (*Mod. Packaging*, 14 (1941), No. 12, pp. 46-47, 106).—In addition to a general discussion of this problem, data resulting from the bacterial analyses of several thousand liquid-tight paper containers, including milk containers, are summarized. A high percentage of these yielded less than 5 colonies per container, and very few exceeded 100 per container, which indicates the high quality of paper stock and the sanitary protection afforded the stock during fabrication of such containers.

**Observations on the composition of Cheddar cheeses,** J. C. MARQUARDT and M. W. YALE. (N. Y. State Expt. Sta.). (*Natl. Butter and Cheese Jour.*, 32 (1941), No. 12, pp. 16-18, 20, 22, 24).—Supplementing an earlier report on this subject (E. S. R., 84, p. 242), data are presented on the salt and moisture contents of various types of Cheddar cheese entered in competition at the 1941 New York State fair. Average values for salt and moisture, respectively, were export Cheddar 1.34 and 37.2, home-trade Cheddar 1.4 and 37.4, sage 1.37 and 37.45, young America 1.37 and 38, pimiento and miscellaneous 1.44 and 39.8, and picnic twins 1.39 and 37.8. Salt content was extremely variable, the

spread between minimum and maximum values exceeding 1 percent in three of the types studied. The spread between minimum and maximum moisture values varied from 4.5 percent in pimienta and miscellaneous types to 8 percent in export Cheddars. The average moisture content of all cheeses was over 2 percent below the legal requirements. Fat analyses revealed that about 50 percent contained less than 30 percent of fat, a percentage below which quality is adversely affected. About 30 percent contained over 32 percent fat, and the remainder contained from 30 to 32 percent fat.

**A new method for making cheese, C. C. FLORA.** (Va. A. and M. Col.). (*Natl. Butter and Cheese Jour.*, 33 (1942), No. 1, p. 16).—The significant feature of the described method is the addition of water to the cheese batch, at the time of cutting the curd, which will lower the acid content of the whey to near 0.12 percent. Otherwise standard methods are followed. It is claimed that in this manner good marketable cheese can be made from milk of low, medium, or high percentage acidity.

**The bacteriology of brick cheese.—I, Growth and activity of starter bacteria during manufacture, J. C. GAREY, E. M. FOSTER, and W. C. FRAZIER.** (Wis. Expt. Sta.). (*Jour. Dairy Sci.*, 24 (1941), No. 12, pp. 1015–1025).—Using a conventional method for the manufacture of brick cheese, experimental lots were prepared using (1) a pure *Streptococcus lactis* starter, (2) a pure *S. thermophilus* starter, and (3) a mixture of the two starter cultures. It was observed during the manufacturing process that *S. thermophilus* practically stopped growth at the third or fourth hour after dipping because of low temperature, whereas the activity of *S. lactis* was not extensive until the latter part of the draining period, and maximum numbers of these organisms were usually reached within 1 or 2 days. At a cooking temperature above 106° F. growth and activity of *S. lactis* was greatly retarded, while a temperature of 112° increased the rate of growth and activity of *S. thermophilus*. When *S. lactis* was the only starter a sour flavor and weak or crumbly body often developed unless special care was taken to control the moisture at dipping. These defects developed if the moisture content at 2 days was higher than 42 percent. A fermented flavor and open texture developed in the cheese with *S. thermophilus* as the only starter. A combination of the two starters gave a better quality cheese than when either was used alone.

**Study of New York State Limburger shows quality improvement in 1941, M. W. YALE and J. C. MARQUARDT.** (N. Y. State Expt. Sta.). (*Natl. Butter and Cheese Jour.*, 33 (1942), No. 1, p. 57).—The score and the salt, moisture, and fat contents of 25 lots of Limburger cheese entered in competition at the 1941 New York State Fair are presented. Bitterness, the most common flavor defect, was noted in 8 of the samples. This condition appeared to be rather definitely correlated with low salt content.

**Italian cheese varieties, J. C. MARQUARDT.** (N. Y. State Expt. Sta.) (*Natl. Butter and Cheese Jour.*, 33 (1942), No. 1, pp. 10–11, 36, 38–39, fig. 1).—Based on direct translations from the Italian, information is presented on the distinguishing characteristics and method of manufacture of Caciocavallo, Provolone, Provolone, and Pecorino Romano types of cheese. The procedures determined at this station for preparing American Provolone-type and Romano-type cheeses are included.

## VETERINARY MEDICINE

[Investigations in diseases of livestock] (*U. S. Dept. Agr., Sec. Agr. Rpt.*, 1941, pp. 211–215).—Reference is made to the control of diseases of horses; effectiveness of phenothiazine against internal parasites; added protection to

the swine industry by closer supervision over the distribution of anti-hog-cholera serum, hog-cholera virus, and similar biological products; suppression of Bang's disease; bovine tuberculosis campaign reaches goal; Federal meat inspection; and livestock quarantines.

[Work in animal pathology and parasitology by the Wisconsin Station]. (Partly coop. U. S. D. A. et al.). (*Wisconsin Sta. Bul.* 453 (1941), pp. 4-10, 23, 61, 62, figs. 3).—Reports of work (E. S. R., 84, p. 668) by S. H. Waxler, C. A. Herrick, C. E. Holmes, D. L. DeGiusti, G. L. Ott, A. I. Coombes, W. Wisnicky, E. H. Spitzer, C. H. Winkler, B. B. Morgan, F. B. Hadley, W. D. Pounen, B. A. Beach, E. G. Hastings, J. R. Wagner, C. A. Elvehjem, J. McCarter, and D. Watson relate to the vaccination of chicks for coccidiosis, experiments with steamed bonemeal and with organic sulfur compounds for control of coccidiosis, rickets in foxes due to unbalanced mineral supplements, Chastek paralysis of foxes a vitamin B<sub>1</sub> deficiency, vitamin A for foxes, deworming of sheep, internal parasites commonly found in horses, mastitis control, relation of wheat gluten to running fits in dogs, and use of low-potency tuberculins.

[Contributions on animal parasitology] (*Jour. Parasitol.*, 27 (1941), No. 6, Sup., pp. 14, 16-23, 24-25, 26, 27, 28-29, 30-31, 35-36, 37, 38).—Among the contributions presented at the annual meeting of the American Society of Parasitologists held in Dallas, Tex., in December 1941 (E. S. R., 86, p. 383), abstracts of which are given, are: The Occurrence of *Dicrocoelium dendriticum* in the United States, by E. W. Price and W. D. Kinchelov (p. 14), The Effects of Sulfaguanidine on Experimental Bovine Coccidiosis, by D. C. Boughton (pp. 16-17), Some Clinical Aspects of Experimental Esophagostomiasis in Cattle, by J. S. Andrews (pp. 17-18), The Biology and Ecology of the Snail (*Stagnicola bulimoides techella* (Hald.)), Intermediate Host of *Fasciola hepatica* Linn., in South Texas, by O. W. Olsen (p. 18), The Effect of Milk Diet on the Development of *Haemonchus contortus* in Calves, by D. A. Porter (pp. 18-19), Sulfaguanidine Feeding as a Control Measure for Cecal Coccidiosis of Chickens, by M. M. Farr and R. W. Allen (p. 20), Effect of a Single Dose of Phenothiazine Upon Egg Production and Viability of the Eggs of Swine Lungworms, by L. A. Spindler and K. C. Kates (p. 20), Skin and Precipitin Tests for the Diagnosis of Trichina Infections in Grain-Fed and in Garbage-Fed Hogs, by L. A. Spindler and J. L. Avery (p. 21), Reactions in Garbage-Fed and in Grain-Fed Hogs to Intracutaneous Injections of Various Diluents, by J. L. Avery (p. 21), Precipitate Formation Around Trichina Larvae in Sera From Trichina-Infected and Trichina-Free Hogs, by L. A. Spindler, J. L. Avery, and H. E. Zimmerman, Jr. (p. 22), and Experimental Infection of Pigs With the Swine Thorn-Headed Worm *Macracanthorhynchus hirudinaceus*, by K. C. Kates (p. 22) (all U. S. D. A.); The Incidence of *Trichomonas foetus* in Wisconsin Cattle, by B. B. Morgan (p. 16), and Immunization Against Coccidiosis by the Use of X-ray Attenuated Oöcysts, by S. H. Waxler and C. A. Herrick (p. 17) (both Univ. Wis.); Hatching Ascaris Eggs in Vitro, by G. L. Graham (p. 17); Losses of *Haemonchus* Larvae Early After Their Administration in Susceptible Sheep, by N. R. Stoll and J. H. Tetley (p. 18); Studies on Bovine Gastro-Intestinal Parasites—VII, The Effects of a Low Plane of Nutrition (Cottonseed Hulls) on Immunity to the Stomach Worm *Haemonchus contortus*, by R. L. Mayhew (p. 19) (E. S. R., 86, p. 383), and Further Data on the Blood Picture in Stomach Worm *Haemonchus contortus* Infections, by E. T. Delaune and R. L. Mayhew (p. 19) (both La. State Univ.); Notes on the Musculature of the Male Genitalia of *Haemonchus contortus*, by W. L. Threlkeld and M. E. Henderson (pp. 19-20) (Va. Expt. Sta.); Limited Tests of Phenothiazine as an Anthelmintic in Goats, by P. D. Harwood and J. E. Guthrie (pp. 20-21); The Duration of Infectivity of Nematode Parasites of Cattle on Florida Pasture With Observations on Re-

sistance of Calves to Natural Re-infection With *Haemonchus contortus*, by D. A. Porter, L. E. Swanson, and T. J. Drake (pp. 22-23) (U. S. D. A. and Univ. Fla.); The Effect of Host Age on the Number of *Trichinella spiralis* Recovered From Rats During the Early Period of Infection, by L. O. Nolf and H. Zaiman (p. 24); The Effects of Immune Serum Upon the Larvae of *Trichinella spiralis* in Vitro, by E. P. Offutt, Jr. (p. 24); Attempted Passive Transfer to Rats and Mice of Immunity to *Trichinella spiralis*, by O. R. McCoy and F. F. Bond (pp. 24-25); The Protective Action of Normal Sheep Serum Against Infections of *Trypanosoma duttoni* in the Mouse, by W. H. Taliaferro and Y. P. Olsen (p. 25); The Trypanocidal Action of Sheep Serum on *Trypanosoma duttoni*, by W. H. and L. G. Taliaferro (p. 25); Quantitative Relationships in Immunity to Hookworm, by G. F. Otto (p. 25); *Hexamita [muris?]* in the Blood of a Mouse, by J. Andrews and M. Reynolds (p. 26); Some observations on *Histomonas* From Wild Pheasants and Domestic Fowls, by D. H. Wenrich (pp. 27-28); Pantothenic Acid and *Eimeria nieschulzi* Infection in the White Rat, by E. R. Becker (p. 28) (Iowa State Col.); Transmission of the Liver Coccidium *Eimeria stiedae* From the Domestic to the Cottontail Rabbit, by H. A. Jankiewicz (p. 28); Life Cycles of Four Species of Intestinal Coccidia of the Domestic Rabbit, by R. L. Rutherford and J. F. Kessel (pp. 28-29); The Occurrence of *Heterodoxus longitarsus* Piaget (Mallophaga: Boopinae) on Dogs in Mississippi, by J. W. Ward (p. 30) (Miss. State Col.); Mechanical Transmission of Shope Rabbit Fibroma by Certain Haematophagous Bugs, by C. B. Philip (pp. 30-31); Removal of Chicken Tapeworms by Host Starvation and Some Effects of Such Treatment on Tapeworm Metabolism, by W. M. Reid and J. E. Ackert (p. 35) (Kans. State Col. et al); The Life Cycle of *Diocotophyme renale*, the Giant Kidney Worm of Mammals, by A. E. Woodhead (pp. 35-36); The Possibility of Chemical Control of the Snail Intermediate Hosts of *Schistosoma mansoni* in Venezuela, by G. W. Luttermoser (p. 36); Effects of Duodenal Mucus of Dogs and Swine Upon the Viability of *Ascaridia lineata* in Vitro, by L. L. Eisenbrandt and J. E. Ackert (p. 36) (Kans. State Col. et al.); Intestinal Resistance to a Second Infection of *Trichinella spiralis*, by A. J. Levin and T. C. Evans (p. 37); and Cultivation Experiments With the Avian Malaria *Plasmodium circumflexum*, by F. Coulston (p. 38).

**Isolation of Coccidioides from soil and rodents.** C. W. EMMONS (*Pub. Health Rpts. [U. S.]*, 57 (1942), No. 4, pp. 109-111).—In the search in Arizona for an animal reservoir of the fungus parasite *C. immitis*, the cause of coccidioidomycosis which occurs sporadically in cattle, sheep, and dogs as an accidental infection, as in man, 105 wild rodents were examined. This fungus was found present upon direct examination or by culture in 25 of these animals, representing 6 species, namely, *Peromyscus crinitus*, *Perognathus baileyi*, *P. penicillatus*, *P. intermedius*, *Dipodomys merriami*, and *Citellus harrisi*. Species of the genus *Perognathus* appear to be especially important hosts, as 21 of 26 specimens had fungus infections. In the San Carlos area of Arizona the fungus has been isolated from the soil and from rodents but not as yet from a human case of the disease. Small rodents appear to constitute an important natural reservoir of *Coccidioides*. This may explain, on the one hand, the presence of the spores of the fungus in wind-blown soil contaminated by infected animals and, on the other hand, the difficulty of isolating the fungus from soil in which it has a highly localized and spotty distribution.

**Manuel de classification et de détermination des bactéries anaérobies [Manual for the classification and determination of the anaerobe bacteria],** A. R. PRÉVOT (*Paris: Masson & Co., 1940, pp. [1]+223*).—This work consists largely of systematic descriptions of the anaerobe bacteria, each presented in a concise, uniform way.

**New and nonofficial remedies, 1941** (*Chicago: Amer. Med. Assoc., [1941], pp. 691+LXX; sup., pp. 30, rev. sup., pp. 53*).

**Sulfapyridine therapy in local infections**, A. H. BRYAN (*Jour. Amer. Vet. Med. Assoc., 100 (1942), No. 778, pp. 73-75*).

**A therapeutic incompatibility between sulfapyridine and quinine**, B. K. HARNED and V. V. COLE (*Jour. Pharmacol. and Expt. Ther., 74 (1942), No. 1, pp. 42-51, figs. 3*).—In the experimental work reported, quinine administered orally with sulfapyridine to rats increased the total amount of sulfapyridine absorbed and excreted in the urine. "The maximal increase was produced by the largest dose of quinine and, using average values, amounted to 44 percent. The increase in the urinary excretion of total sulfapyridine represented principally an increase in the acetylsulfapyridine. The largest dose of quinine produced an average increase of 96 percent in the excretion of acetylsulfapyridine. This effect was not accompanied by an increase in the volume of urine. Quinine depressed the free sulfapyridine in the urine. The maximal decrease observed was 33 percent. Atabrine substituted for quinine produced no comparable effect."

**An in vitro study on the synergistic action of sulfamido compounds and azochloramid upon various pathogenic microorganisms**, E. NETER (*Jour. Pharmacol. and Expt. Ther., 74 (1942), No. 1, pp. 52-60*).—It was revealed in an in vitro study on the combined antibacterial activity of sulfamido compounds and azochloramide that "(1) azochloramide used in combination with sulfanilamide, sulfathiazole, and sulfadiazine may exert greater bacteriostatic activity toward group A hemolytic streptococcus than does either compound alone in like or somewhat higher concentrations; (2) a slight increase in bacteriostatic activity toward group D hemolytic streptococcus was obtained when azochloramide was used in conjunction with sulfanilamide; (3) the combined use of azochloramide and sulfanilamide, sulfapyridine, sulfathiazole, or sulfadiazine resulted in greater inhibition of growth of pneumococcus type I than did that of either drug alone in like or somewhat higher concentrations; [and] (4) the combined use of sulfathiazole or sulfadiazine and azochloramide retarded the growth of *Staphylococcus aureus hemolyticus* to a greater extent than did either drug in like or higher concentrations."

**Conjugation of sulfanilamide by a pathological tissue in vitro**, A. GOTH (*Jour. Pharmacol. and Expt. Ther., 74 (1942), No. 1, pp. 71-74*).—It was found that the fowl pox lesion is able to conjugate sulfanilamide in vitro. The relationship between this conjugating capacity and the glucose-splitting power of the fowl pox lesion is considered.

**Binding of sulfonamides by plasma proteins**, B. D. DAVIS (*Science, 95 (1942), No. 2455, p. 78*).

**Some toxicological and pharmacological properties of gramicidin, tyrocidine, and tyrothricin**, H. J. ROBINSON and H. MOLITOR (*Jour. Pharmacol. and Expt. Ther., 74 (1942), No. 1, pp. 75-82, figs. 3*).—In the work reported the acute, peroral, intraperitoneal, and intravenous toxicity of tyrothricin, gramicidin, and tyrocidine was determined in 1,200 Swiss mice and 210 albino rats. None of these compounds was toxic when given by mouth, but upon parenteral administration all proved definitely toxic, gramicidin and tyrothricin considerably more so than tyrocidine. "Daily parenteral administration of 2 mg. of gramicidin or tyrothricin per kilogram to dogs caused death within 2-8 days. During this period the dogs lost their appetite and weight and secreted excessive amounts of saliva. Their red blood counts dropped in some cases from 6,000,000 to 3,500,000 per cubic millimeter. In isolated organs as well as in situ, tyrocidine produced greater pharmacological changes than tyrothricin or gramicidin, possibly due to its greater solubility in water. None of the drugs has a pro-

nounced specific effect on the respiratory or circulatory system. Large single doses are usually tolerated without any marked effect, while repeated administrations even of small doses cause a fall of blood pressure and impairment of respiration. With lethal doses the respiration stops shortly before the heart. Concentrations of gramicidin suspensions up to 0.5 percent are not irritating upon instillation into the conjunctival sacs of rabbits. However, application of the dried material produces marked conjunctival irritation and a long-persisting opaqueness of the cornea. When injected subcutaneously or intradermally the preparations remain unabsorbed for a long period of time."

**Human encephalitis due to the virus of equine encephalomyelitis, C. M. EKLUND** (*Vet. Med.*, 37 (1942), No. 2, pp. 70-76).—This summary of the present status of knowledge of the subject is presented with a list of 86 references to the literature.

**Hemorrhagic septicemia in mule deer, E. R. QUORTRUP** (*North Amer. Vet.*, 23 (1942), No. 1, pp. 34-36, figs. 2).—An outbreak of a disease among mule deer on the Stansbury Range in Tooele County, Utah, investigated in the fall of 1940, was diagnosed through post-mortem and bacteriological examinations and animal inoculation as due to *Pasteurella bovisepitica*. In an examination of 50 miles of range made on September 4 and 5, 59 dead deer were found, but no sick deer were observed, indicating that the losses had occurred through the month of August, with the peak probably about the middle of the month. In the course of laboratory work a pure culture was obtained through guinea pig inoculation from deer lung tissue which had been frozen in the ice box for as long as 3 weeks.

Oattle were observed grazing on the same range used by the deer, but none was found or reported afflicted. In order to prevent infective organisms being carried downstream to the range of healthy animals below, all carcasses in and near streams were removed and incinerated by the Forest Service and State Game Department officials.

No abnormal losses were observed during the 1941 hunting season, and the deer appeared to be as plentiful on the range as usual.

**Rabies** (*Union So. Africa Dept. Agr. and Forestry Bul.* 214 (1941), pp. 31, figs. 9).—A practical summary of information.

**Bovine tuberculosis eradication in the United States and its resulting beneficial effects on human health, J. A. MYERS**. (Univ. Minn.). (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 778, pp. 12-18).

**Tuberculosis in the buffalo, S. HADWEN** (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 778, pp. 19-22, figs. 3).—This discussion relates to a herd of tubercular buffaloes maintained in Canada for more than 26 yr. The disease did not interfere with the growth of the herd, which made considerable gains. There was no contact with animals other than members of the deer family, which with the exception of the mule deer readily acquired tuberculosis from the buffaloes.

**Further studies on the significance of suspicious agglutination reactions for Bang's disease, C. P. FITCH, W. L. BOYD, M. D. KELLY, and L. M. BISHOP**. (Minn. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 778, pp. 23-26).—Studies in continuation of the earlier work noted (E. S. R., 77, p. 698) are reported, which extended over a period of 12 yr., nearly all of the animals being observed for a period including at least one calving. Bacteriologic examinations were made of the milk, colostrum, placentas, vaginal discharges, fetuses, and calves which died shortly after birth to determine whether the animals were excreting *Brucella abortus*. Agglutination titers of the blood and milk were determined at regular intervals. Negative control animals were

housed with suspect animals in each barn and were allowed in the same paddocks. All animals were isolated at the time of parturition. *B. abortus* was isolated from two animals with suspicious agglutination titers and from two of the controls. The isolation of *B. abortus* from 9 of 97 animals which entered the experimental herd with titers complete at 1:100 or incomplete at 1:100 suggests that these animals may be a sufficiently dangerous source of infection to warrant their removal from a herd.

A clinical survey of intoxications of cattle by Sudan grass (*Sorghum sudanense*), A. L. ROSE (*Austral. Vet. Jour.*, 17 (1941), No. 6, pp. 211-219).—Account is given of a number of serious losses from Sudan grass poisoning supported by a tabulated statement of the principal data as evidence that pure Sudan grass may be just as toxic as are its hybrids with sorghum. The seasonal conditions which predispose to intoxications are those in which rain falls during the heat of the summer, inducing optimum growth of the plant. Sudan grass which has been eaten to the ground by grasshoppers and which is regrowing rapidly after rain has proved, in almost all cases, to be at the dangerous stage. A few mortalities on other sorghum species such as amaranth, Johnson grass, and broom millet are also recorded. Particulars are given of what appears to be a specific line of treatment, especially if adopted along with symptomatic treatment. It is concluded that none of the *Sorghum* spp. is safe to feed off to cattle at any stage of growth.

[Work with sheep parasites by the Georgia Station] (*Georgia Sta. Rpt.* 1941, pp. 77-78).—The work of the year (E. S. R., 84, p. 105) relates to worm control in sheep and control of the sheep tick and the sheep louse *Trichodectes ovis*.

The incidence of coccidia and intestinal nematodes in sheep at the Utah State Agricultural College and vicinity of Logan, D. M. HAMMOND and G. A. HAMILTON. (*Utah State Agr. Col.*). (*Utah Acad. Sci., Arts, and Letters, Proc.*, 18 (1940-41), pp. 69-71).—All of 67 sheep that were given fecal examinations proved to be infected with coccidia. The incidence of species as determined by the unsporulated oocyst was similar in general to that found by Christensen (E. S. R., 80, p. 396) in sheep from Idaho, Wyoming, Maryland, and New York. Sheep at the college kept in clean pens throughout the year and fed from feed racks were found to have a significantly lower rate of infestation with intestinal nematodes than Karakul sheep kept in pastures or in small enclosures and fed on the ground.

A skin disease of sheep due to an ectoparasitic mite, *Psorergates ovis* Womersley 1941, H. B. CARTER (*Austral. Vet. Jour.*, 17 (1941), No. 6, pp. 193-201, pls. 2, figs. 6).—Description is given of the disease and of the mite *P. ovis* which is responsible for a chronic irritation of the skin and much damage to the fleece. The principal lesions produced are a hyperkeratosis of the skin, with an excessive amount of dry, crumbling scurf. The staple becomes stringy with a tip which is dry and spiral-pointed, and its tensile strength may be seriously reduced. Some degree of coting may occur in the fleece of advanced cases. Loose tassels of tangled fibers may appear on the sides and flanks, and considerable patches of the fleece may be lost. As yet the infestation has only been observed among fine-wool merino sheep, of which all ages and sexes may be affected, but other types of merino and other breeds of sheep may be susceptible. The course of the infestation is slow, and the most serious cases tend to occur among sheep over 3 yr. old. The life history of the parasite and effective methods of treatment and control remain to be worked out. It is pointed out that members of this genus appear to be recorded only as ectoparasites of mice and voles.

[Studies on baby-pig mortality].—I, **Acute hypoglycemia in newly born pigs (so-called baby pig disease)**, R. GRAHAM, J. SAMPSON, and H. R. HESTER. (Univ. Ill.). (*Soc. Expt. Biol. and Med. Proc.*, 47 (1941), No. 2, pp. 338-339).—A brief account is given of an unidentified highly fatal affection of newborn pigs, sporadic outbreaks of which have come to the attention of the Illinois Experiment Station during the last 8 yr. In the typical syndrome presented by pigs that suffer from the disease, apparently normal litters at approximately 24 to 48 hr. of age show symptoms of shivering, dullness, and inappetence. Affected pigs often emit a weak crying squeal. Coincident with the loss of appetite and weakness, the hair coat becomes rough and the affected pigs leave the nest and lapse into coma. Death of several or all pigs in the affected litters often occurs within 24 to 36 hr. after the first symptoms are manifested. The extent of the loss has ranged from 1 to 22 litters, representing approximately 5 to 95 percent of the pigs farrowed in some herds. At autopsy no gross pathologic lesions have been observed. Search of the tissues for a causative agent has given negative results. In chemical analyses of the blood abnormal amounts of the blood sugar were consistently encountered. Contributory evidence in support of the possible primary significance of acute hypoglycemia has been observed in the therapeutic response in naturally affected pigs following repeated injections of glucose solution. Pigs in the early stage of the disease show improvement in 2 to 3 hr. following dextrose therapy, while repeated injections of dextrose together with forced feeding of milk have demonstrated that the life of naturally affected pigs may be prolonged and that in some cases the treated pigs may recover. However, glucose therapy even if repeated appears ineffective in the terminal stages of the disease.

**Studies on baby-pig mortality.**—II, **Further observations on acute hypoglycemia in newly born pigs (so-called baby-pig disease)**, J. SAMPSON, H. R. HESTER, and R. GRAHAM. (Univ. Ill.). (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 778, pp. 33-37, figs. 3).—Reporting further (see above), added support of the primary role of hypoglycemia in baby-pig disease is found in the observation that newly born pigs are apparently highly susceptible to the development of an intense fasting hypoglycemia during the first 12 and perhaps 24 hr. or longer after birth and relatively refractory to fasting hypoglycemia at the age of from 120 to 140 hr. It has been demonstrated that newly born, well-nourished pigs, 5 to 6 days old, are relatively refractory to the development of severe hypoglycemia when subjected to a fast of 1 week, during which time all of the stored liver glycogen would undoubtedly be exhausted. This observation suggests that the newborn pig requires a period of several days for the regulatory mechanism involved in the production of liver glycogen from noncarbohydrated material, such as tissue protein, to function effectively. If this mechanism is not ready and the two common sources of blood sugar—(1) absorption from the intestine and (2) reserve glycogen stored in the liver—fail, irrespective of cause, to maintain a safe sugar level, a fatal hypoglycemia becomes imminent.

**Viability of eggs of the swine thorn-headed worm *Macracanthorhynchus hirudinaceus***, K. C. KATES. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 2, pp. 93-100).—Laboratory tests were made of the effects of high and low temperatures, drying, alternate wetting and drying, and ultraviolet irradiation on the viability of eggs of *M. hirudinaceus*. The ability of the contained larvae to infect grubs of the green June beetle was used as a criterion. Eggs in water were destroyed by instantaneous exposure to a temperature of 70° C. and by 10 minutes' exposure to a temperature of 60°. In one series of preliminary tests, not so well controlled, a small number of eggs survived higher temperatures. The majority of eggs in water and in a dried condition survived continuous exposure to temperatures ranging from -10° to -16° for as long

as 140 days, when the test was terminated. No appreciable reduction in number of viable eggs was observed in dry preparations exposed for 50 days at temperatures of 5° to 9° and 37° to 39° and for 265 days at temperatures of 21° to 26°. Alternate wetting and drying at temperatures of 37° to 39° destroyed the viability of eggs on soil in 368 days. On the other hand, eggs subjected to alternate wetting and drying at temperatures of 2° to 5° were still viable after 551 days. Ultraviolet irradiation applied at a distance of 18 in. destroyed nearly all the dry eggs in a single layer in 10 min. Some eggs in films several eggs thick survived for 40 min. Some eggs in shallow water survived irradiation for as long as 120 min. The results are considered to explain the earlier findings that eggs of this worm may be viable on soil for as long as 3.5 yr. under Beltsville, Md., conditions (E. S. R., 86, p. 383).

**The effect of phenothiazine on the hemoglobin concentration, erythrocyte count, and leucocyte count of swine,** E. C. McCULLOUGH and L. SEGHEITL (Wash. Expt. Sta.). (*Vet. Med.*, 37 (1942), No. 2, pp. 80-84, figs. 2).—The results of an investigation of the effect of phenothiazine on hemoglobin concentration and erythrocyte and leucocyte counts are reported in detail in table form, and graphs are given showing the effect of this drug upon both the red cell count and the hemoglobin. Daily administration of therapeutic doses of phenothiazine, even over periods as long as ever would occur under practical conditions, was without apparent deleterious effect upon the swine used. Daily repeated administration of much larger doses over longer periods produced a marked and significant, although not fatal, decrease in the hemoglobin concentration of the blood and in the erythrocyte count. No significant change occurred in the leucocyte count. Although based upon a limited number of animals maintained under a single set of conditions, the data obtained indicate that the amounts of phenothiazine usually recommended for swine possess a large factor of safety.

**Sulfaguanidine feeding as a control measure for cecal coccidiosis of chickens,** M. M. FARR and R. W. ALLIN. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 778, pp. 47-51, figs. 2).—No symptoms, lesions, or coccidial forms were found in fowl fed a 2 percent sulfaguanidine mash for 3 days before inoculation with *Eimeria tenella* and for 9 days thereafter. Birds that were fed a 1 percent sulfaguanidine mash over the same period developed very light infections but showed no symptoms or severe lesions. Birds receiving either a 3 or 5 percent sulfaguanidine mash daily after the appearance of blood in the droppings were not significantly benefited, although oocyst production was sharply reduced. Birds protected from an initial infection of cecal coccidiosis by sulfaguanidine were highly susceptible to a reinoculation of 95,000 oocysts 29 days later. The average gain in weight of the inoculated controls was less than that of the birds receiving prophylactic doses of sulfaguanidine mash, but greater than that of the birds receiving medicated mash as a curative agent.

**The present status of avian encephalomyelitis,** E. JUNGHER and E. L. MINARD. (Univ. Conn.). (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 778, pp. 38-46).—This discussion is presented with a list of 40 references to the literature cited.

**Fowl leukosis—manifestations, transmission, and etiological relationship of various forms,** E. P. JOHNSON (*Virginia Sta. Tech. Bul.* 76 (1941), pp. 21, figs. 14).—The manifestations in birds injected with (1) Virginia strain leucosis agent and (2) B. A. I. strain A leucosis agent in the course of experimental work on the transmission of fowl leucosis are reported in tables. The blood reaction in birds inoculated with these two strains and which became affected as determined from periodic blood smears and finally from gross and histologic post-mortem findings, the manifestations in control birds during the

course of the experiment, and the number of birds inoculated and incidence of disease in each group are also presented in tables.

It was found in experimental transmission of fowl leucosis through chick embryos that intravenous injections resulted in a much higher incidence of successful transmissions than when the material was placed on the chorioallantoic membrane. Likewise, very little difficulty was encountered from contamination and from the introduction of nonspecific infectious materials when the intravenous method was used. However, embryos did not seem to be more susceptible to the leucosis materials than did day-old or even week-old chicks. Young chicks appear to be most suitable for transmission experiments.

In an experiment with "Leghorn chicks from a source relatively free from any form of leucosis and having a history known for several years, comparative data on results of injections with leucosis materials used over a period of years (Virginia strain) and leucosis materials (B. A. I. strain A) were obtained. The latter strain had produced in susceptible Rhode Island Red chicks and embryos for several passages entirely erythroblastic leucosis and what appears to be almost completely hemocytoblastic, with very little if any differentiation taking place. When these leucosis materials from two different sources were inoculated into Leghorn birds whose history indicates comparative freedom from natural occurrence of the disease the results suggest clearly that the birds receiving the inocula determine to an important degree the incidence, course, and form of leucosis that will result in transmission experiments. These results, moreover, give encouraging support toward the possibility of breeding genetically resistant birds whose offspring rarely develop any form of the leucosis complex. In this experiment 50 Leghorn birds were inoculated with B. A. I. strain leucosis agent and 23 or 46 percent of these developed some form of the disease. Sixty-three similar birds were inoculated with Virginia strain leucosis agent and 21 or 33.3 percent developed some form of the disease. Of 98 similar birds from the same source and used to control the experiment, only 8 developed any form of the disease. The high incidence of hemocytoblastoma (lymphocytoma) which occurred in these experiments leaves no doubt as to the transmissibility of this form of the disease. The relatively high incidence of this form resulting from an inoculum that was producing almost exclusively erythroblastic leucosis for several passages in highly susceptible Rhode Island Red chicks furnishes additional evidence in favor of the view that a common causative agent may produce a multiplicity of expressions of this disease complex.

"Of 26 ring-necked pheasant chicks (*Phasianus torquatus* Gmelin) inoculated intravenously with blood from a case of neural lymphomatosis due to Virginia strain leucosis agent, only 3 became affected during an observation period of 12 mo. One of these had neural lymphomatosis and 2 had the visceral form. None of 14 similar birds kept as controls developed symptoms of any form of the disease, nor were any lesions present at autopsy suggestive of any form of the disease."

Included is a list of 15 references to the literature cited.

**The anti-perosis complex**, L. R. RICHARDSON and A. G. HOGAN. (Mo. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 2, pp. 459-461).—It is shown that at least one nutrient in addition to choline and manganese is required to prevent perosis in chicks, and that this substance is not identical with any of the recognized vitamins. The fuller's earth adsorbate of the water extract of liver and a 0.2 N ammonia eluate of the fuller's earth adsorbate are fair sources of the nutrient. The perosis due to a deficiency of the unidentified factor is similar to that produced by a deficiency of manganese or choline but is usually less severe. It is pointed out that were it possible to

supply all other essential unrecognized vitamins in a concentrated form the chicks in all probability would grow faster and probably develop more severe symptoms.

**Eradication of pullorum disease from turkey flocks, W. R. HINSHAW and E. McNEIL.** (Univ. Calif.). (*U. S. Livestock Sanit. Assoc. Rpt.*, 44 (1940), pp. 178-194).—A plan prepared by the California Experiment Station for eradicating pullorum infection from the flocks of 80 members of a San Diego County, Calif., turkey growers' association, containing 22,000 breeder hens, that was inaugurated on July 1, 1939, is described and the progress reported. The project adopted includes testing all birds for carriers by use of the standard tube agglutination method (1:25 dilution) at monthly intervals until one negative test is obtained, field supervision of flocks, inspection of hatcheries, and frequent educational conferences. When the 80 flocks, containing 28,810 birds, were tested in the 1939-40 season, 40 of them (8,718 birds) were free on first test, and by the end of the season a total of 64 were free (80 percent of the flocks and 68 percent of the turkeys). The remaining 16 infected flocks were tested at monthly intervals until the end of the hatching season. There was good evidence that the majority of these losses in 1939 resulted from the purchase of eggs from three ranches. In 1940, 81 percent of the flocks and 81 percent of the turkeys (17,181 birds) were free on first test as compared with 50 percent of the flocks and 30 percent of the turkeys free on the first test in 1939. The infected flocks of 1940 were either sold or cleared by retest, so that all flocks now supplying eggs have the equivalent but unofficial status of the U. S. Pullorum Passed grade. A total of 600,000 eggs were sold to midwestern and eastern hatcherymen in 1939-40 without a single complaint of losses from pullorum disease. Data on 49,890 tests made during 1939-40 showed that 1.77 percent of the males and 4.23 percent of the females were reactors. In no instance in 1940 was there an outbreak of pullorum disease in a flock which came from eggs laid by a negative flock (either on first test or by retest) and hatched by a hatchery accepting only eggs of like status.

This work has been referred to in an article by Harshfield (*E. S. R.*, 85, p. 541) the implication in the abstract that the studies were carried on in Colorado being erroneous.

## AGRICULTURAL ENGINEERING

**[Agricultural engineering work of the Department]** (*U. S. Dept. Agr., Sec. Agr. Rpt.*, 1941, pp. 222-227, 230-233).—The work of the Rural Electrification Administration and its relation to national defense requirements is reported upon, as is also the work of the Bureau of Agricultural Chemistry and Engineering on farm machinery and on heating, storage, and electrification.

**[Agricultural engineering investigations of the Bureau of Agricultural Chemistry and Engineering]** (*U. S. Dept. Agr., Bur. Agr. Chem. and Engin. Rpt.*, 1941, pp. 69-80).—The topics reported upon are farmhouse research; buildings for livestock; silage-pressure studies; potato, corn, wheat, and grain-sorghum storage; pest-control equipment; fertilizer-distributing and crop-production machinery; ginning and packing cotton; fiber-flax processing; and uses for electricity in farming.

**[Agricultural engineering investigations by the Wisconsin Station]** (*Wisconsin Sta. Bul.* 453 (1941), pp. 49-57, 63-64, figs. 6).—The work reported consists of a comparative experiment by S. Witzel, E. Heizer, E. Zehner, and A. Elneron on open shed as against insulated and fully equipped dairy barns; brooder house experiments and design of a satisfactory home-made electric brooder, both by H. D. Bruhn; the use, by F. W. Duffee, of combine engines to do

additional belt jobs to justify their extra cost; design of a new crop blower and a new wagon box for chopped forage, both by Duffee, Bruhn, and G. H. Larson; practical bituminous channel linings for terrace outlets, by H. B. Atkinson and R. S. Calkins (coop. U. S. D. A.); the determination by oxidation-reduction potential measurements of the degree of sewage purification and the condition of the sludge produced in the activated sludge method, by G. A. Rohlich, W. B. Sarles, and L. H. Kessler; and the chlorination of raw sewage, by D. H. Hunter, N. W. Staalson, and Sarles.

**More rational "normal" proposed, J. C. MARE** (*Agr. Engin.*, 22 (1941), No. 9, p. 315).—The average or arithmetical mean may fail to express the usual, typical, or ordinary condition in accordance with the common conception of the term. The "median," the quantity exceeded in half the cases and not reached in the other half, may often be more nearly representative of the "normal" in the commonly accepted sense. Examples taken from a meteorological record showed a use of the arithmetical mean as a normal capable of the absurdity of representing the rainfall for a given month as below the normal for that month in 74 out of 100 yr.

**Hydraulics of water in unsaturated soil, L. A. RICHARDS.** (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 9, pp. 325-326, figs. 6).—This is a simplified exposition of the theoretical and practical principles of the soil moisture tensiometer.

**Hydraulics of sprinkling systems for irrigation, J. E. CHRISTIANSEN.** (Univ. Calif.). (*Amer. Soc. Civ. Engin. Proc.*, 67 (1941), No. 1, pp. 107-125, figs. 12).—In 1932 (about 2 yr. after portable systems for sprinkling agricultural crops were first used in California) the Division of Irrigation of the University of California began a study of sprinkling, principally to determine (1) the hydraulic characteristics of rotating sprinklers, (2) the loss of water by evaporation, (3) the hydraulic characteristics of sprinkler lines, (4) the cost of applying water by sprinkling, and (5) the general success of sprinkling as a method of irrigation. The present paper is concerned with the first three of these subjects.

From field observations and from an analysis here given, it is concluded that sprinklers must be placed closer together than is indicated by the study of symmetrical patterns. The usual spacings of 20, 30, and 40 ft. along the line and from 50 to 70 ft. between lines give fair results when there is adequate pressure and little wind. The customary spacings of from 60 to 90 ft. both ways for stationary overhead orchard systems, however, cause an appreciable variation in application. For evaporation from the spray an expression was derived from the general evaporation formula by assuming that the insolation, the conduction, and the back radiation are negligible and can be omitted. The sensible heat is indicated by the change in the temperature of the water. Loss from this cause was found to be less than 1 percent. Loss from the wet surface of soil and plants during and following the application of water probably exceeds that from a free water surface, however, because of the relatively larger area exposed, and, although the rate decreases rapidly as the surfaces dry and becomes negligible after about a week, during this time the total loss may have exceeded an inch of water. One of the practical results of the analysis of sprinkler line hydraulics is that of emphasizing the advantages of using two short lines supplied from a source through the center of the field instead of a single line of twice that length supplied from a source along one side of the field.

**A comparative study of standard agars for determining bacterial counts in water, W. L. MALLMANN and R. S. BREED.** (Mich. and N. Y. State Expt. Stas.). (*Amer. Jour. Pub. Health*, 31 (1941), No. 4, pp. 341-343).—The old

standard agar (used for milk analyses prior to 1939) and the new standard (TGEM) agar were used in parallel tests on various types and sources of water. Plate counts on the new agar were consistently higher, but the differences were not considered significant, leading to the conclusion that the new standard agar could be substituted for the old for determining the bacterial content of water supplies without causing significant misinterpretations of data.

**Experiences in operating a chemical-mechanical sewage treatment plant,** G. J. SCHROEFFER (*Amer. Soc. Civ. Engin. Proc.*, 67 (1941), No. 1, pp. 61-92, figs. 3).—The author presents data concerning the performance of the plant and the cost of operation and maintenance, as well as on the improvement of the Mississippi River which has resulted from its first 2 yr. of operation. Some of the problems that arose in early operation, the methods used to overcome them, and other improvement changes which have been incorporated to simplify operation or effect economies are discussed.

**Consolidation of elastic earth layers,** D. L. HOLL (Iowa State Col.). (*Iowa State Col. Jour. Sci.*, 16 (1942), No. 2, pp. 319-328).—The author presents a mathematical analysis of saturated earth layers of finite and infinite depth. In the axially symmetric case several types of boundary conditions are considered.

**Gravel-rock overfall structures,** T. P. POWELL (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 11, pp. 384-385, figs. 7).—This method of construction is intended to furnish adequate soil protection with a minimum requirement of material, skill, and time. The necessary filter is produced by making the drop excavation with a 4 : 1 slope on the channel bottom, placing gravel-filled trenches across it and along the sides, adding a 2-in. overall layer of gravel, and shingling the surface with rock in a single layer except at the overfall. At the overfall the rock layer is double, with small, odd-shaped material and gravel dumped behind it to fill the space provided. Correct placement of intermediate size material is especially emphasized, each rock being placed with a downstream edge touching that of another and with as large a V crevice opening upstream as is possible. The crevices are to be filled with graded material.

**Terrace system planning to reduce point rows,** E. C. BUEE (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 9, pp. 321, 324, figs. 2).—To reduce point-row areas to a minimum and eliminate all possible sharp turns and bulges in terrace lines, all terrace systems are planned on topographic maps. A survey crew composed of three or four men makes a topographic map of the field to be terraced. The contour interval usually will vary from 1 to 5 ft., depending on the slope. The completed map is given to a trained planning engineer, who, with due reference to the farm, farm equipment, and farming methods used, designs the terrace system on the topographic map. The survey crew then lays this system out on the farm. The entire cost for the plan should not exceed 7 ct. per acre on slopes ranging from 0.5 to 3 percent. This type of planning can also be applied to water erosion problems in relatively small fields with steep slopes.

**Outlet design for terraced lands,** D. CHRISTY (Tex. A. and M. Col.). (*Agr. Engin.*, 23 (1942), No. 1, pp. 12-14, fig. 1).—The author discusses the determination of the values required for the  $Q=CIA$  equation, presenting a nomogram for the determination of  $C$ . He reaches the following, among other, conclusions: The vegetated ditch becomes the least expensive constructed ditch on slopes greater than 4 percent. However, the vegetated ditch outlet cost (from \$11 to \$13.50 per acre) is, in general, more than the terracing system is worth when the cost of the terracing is added to it. It may be cheaper and more feasible to turn the water onto a strip of waste- or low-value land to allow that strip

to wash away than to try to protect the outlet. This practice is considered satisfactory only where rock is near the surface.

Of a large number of vegetated outlet ditches examined about 80 percent were satisfactory, but when the design velocity was less than 2 ft. per second silting caused a high percentage of failures. At design velocities over 8 ft. per second, on the other hand, the percentage of failures due to erosion was high. The road ditch may be a satisfactory outlet if suitable cooperation between the farmer and the highway department can be secured.

A concrete-lined outlet ditch is cheapest when the steepest part of the field is used as an outlet but is difficult to design (high velocity introducing some special requirements), and is costly in part because of the need for expensive checks at the foot of the slope. The service record of these outlets was excellent, but the cost was high.

The rational run-off formula, while subject to considerable error, will give satisfactory results in the hands of the average agricultural engineer. "The best outlet engineer is one who can, after a critical analysis of labor and materials available, design the least expensive serviceable outlet, . . . not the man who can, with unlimited funds, labor, and material, build a great monument."

**Sawdust-concrete test results, L. W. NEUBAUER.** (Minn. Expt. Sta.). (*Agr. Engin.*, 21 (1940), No. 9, pp. 363-365, figs. 5).—A sawdust-concrete floor was placed in a hog barn. Some of the mixtures used set very slowly. Testing of 698 cylinders made up from 11 species of wood were then made. Kind of wood, size of particles, proportions, water: cement ratio, age, and method of curing were recorded. With some sawdusts little strength was secured, and none of the sawdusts gave much strength. If enough cement was used to give strength the insulation value was lost. The soluble vegetable matter in a given sawdust was found to be an index to the strength of the concrete made from that sawdust. Because of the variables noted it is difficult to give safe rules for making sawdust concrete. It is advisable to make a trial batch at least 2 days before mixing sawdust concrete in quantity.

**What is new in farm machinery, E. A. SILVER.** (Ohio Expt. Sta.). (*Agr. Engin.*, 22 (1941), No. 11, pp. 381-383, 385, figs. 2).—This is a general discussion of needs and current practice, noting progress in hay harvesting equipment, corn combining, hay transportation and green grass handling, harvesting of alfalfa for artificial dehydration, etc.

**Power alcohol in tractors and farm engines, E. L. BARGER.** (Kans. State Col.). (*Agr. Engin.*, 22 (1941), No. 2, pp. 65-67, 78, figs. 6).—The author tabulates physical properties of mixtures of anhydrous ethyl alcohol denatured for motor-fuel use with tractor fuels including regular and third-grade gasoline and distillates. He reports octane numbers for alcohol admixtures of from 0 to 25 percent with regular, third-grade, and third-grade leaded gasolines and four distillates, and gives various cost data on the basis of the price of 25 ct. per gallon, which was paid for the alcohol used in these experiments. A supply at this figure is said to be no longer available. About 3.5 times as many B. t. u. were obtainable from gasoline, and about 5.5 times as many from distillate, per unit of cost as from alcohol. Fuel costs per horsepower-hour and per acre in plowing with a tractor-drawn 2-bottom, 14-in. plow were determined, as were also distillation characteristics of the mixtures, separation temperatures, thermal efficiencies as related to brake horsepower, etc. The alcohol and alcohol blends gave 33.5 percent higher maximum horsepower than did the 46.5 octane gasoline with which the alcohol was mixed, and the 15 and 25 percent alcohol mixtures gave intermediate values. The thermal efficiencies of the alcohol and mixtures were greater than those of the gasoline, and the blends were equal

to or better than the straight gasoline in specific fuel consumption while the 100 percent alcohol ran a good bit higher. In terms of horsepower-hours per gallon, the blends were equal to or better than the gasoline, but 100 percent alcohol fell short. In fuel cost per horsepower-hour, the gasoline was lowest, except at heavy-load operation where detonation was serious, when the 15 and 25 percent blends were equal to the gasoline. The 100 percent alcohol fuel cost curve ranges about 3 times as high as the 100 percent gasoline curve. Similar engine tests on alcohol-distillate mixtures are reported.

**Tractor stop-hitches, A. W. CLYDE.** (Pa. Expt. Sta.). (*Agr. Engin.*, 23 (1942), No. 1, pp. 5-8, figs. 7).—The spring drawbar, though again in use for some plows on small tractors, is usually inadequate. Adding a mechanism to declutch the tractor when the drawbar pull exceeds the normal pull by a predetermined force improved the protection of the plowshares. A complete release relieving the spring entirely of the normal pull and so leaving its entire capacity available for stopping the tractor provided against damage by heavier tractors or higher speeds. A medium size of this device was found to have a capacity adequate for a 4,500-lb. tractor going nearly 3 miles per hour on level ground (17,300 in.-lb.). It is pointed out, however, that the spring alone as a means for stopping the tractor has the two inherent defects of a force varying from zero or a low value to a maximum (whereas a more nearly constant force would be preferable), and lack of provision for releasing energy stored in the spring. For dissipating the spring energy a hydraulic cylinder was built into the hitch above noted, check valves in the piston being provided to facilitate recoupling. This combination made both the stopping and recoupling very smooth. The constant resistance permitted fair protection even of cast shares on one- and two-bottom plows without extreme stopping distance. Some further devices of the same general nature are discussed. A calculation method to determine certain design factors for such hitches is shown, together with a calculation of the hydraulic cylinder orifice areas based on principles related to those of gun recoil control mechanism.

**A simple power wood saw, M. A. SHARP.** (Univ. Tenn.). (*Agr. Engin.*, 22 (1941), No. 9, p. 310, fig. 1).—Reciprocating motion is obtained by driving an old-type reversing steering gear with a 0.25-hp. motor pulley, ratio of 2.5:8. The motion is applied to a 3.5-ft., one-man crosscut saw. The drive bar, thrust bar, mounting of motor, and gear sets are described. A photograph shows the general nature of the set-up.

**Machinery for sugar cane production, H. T. BARR.** (La. State Univ.). (*Agr. Engin.*, 22 (1941), No. 9, pp. 322, 324, fig. 1).—The author describes correct practice in Louisiana cane growing and notes the machines employed.

**Machinery for sweet potato production, J. W. RANDOLPH.** (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 11, pp. 386-388, figs. 4).—Although sweetpotato starch has obtained commercial acceptance, increasing demand, and premium prices, the crop production costs must be lowered from an estimated average of 25 ct. per bushel to a figure permitting profitable factory delivery at from 10 to 15 ct.

For seedbed preparation the cotton growers' equipment and methods were found generally suitable, except that sweetpotatoes need a high bed during the entire growing season, whereas cotton beds are comparatively low and the small power units available give shallow tillage. This tends to develop a definite plow sole and limit yields. Costs for plants can be reduced by the use of available information and home-made equipment from \$17.50, for close spacing of plants from commercial sources, to about \$3 per acre. Current cultivation practice is briefly noted. With reference to harvesting, it is pointed out that dirt, "strings" or enlarged roots, and rot are the only restrictions,

giving opportunity for the development of high-capacity digging and transportation methods without regard to roughness of handling, and various improvements resulting in lowered harvesting costs have been made. The rod type mechanical white potato digger is not effective when the sweetpotato vines are green and rank. Fair results have been obtained with this digger when the vines were previously hoed from the row or by pulling the digger with a tractor equipped with an A-frame vine cutter (a special disk-hiller attachment on a standard cultivator frame). A direct-mounted tractor unit developed by the Bureau of Agricultural Chemistry and Engineering was extensively used during two seasons with excellent results. In one field, previously harvested with mule equipment, this unit gathered an additional 30-35 bu. per acre (from 15 to 22 percent increased yield). Another machine, used only in 1940, was a combination digger and truck loader. For collecting the dug crop, use of the bagging sled has become common practice, saving much time and labor. An experimental rubber-tired cart has been found preferable to the sled, however, because a greater number of bags can be handled and pulled to the "turn row" with the same mule power.

**Automatic feed control for small feed grinders, C. J. HURD** (*Agr. Engin.*, 22 (1941), No. 2, p. 69, figs. 2).—The current supplying the motor is passed through a solenoid containing a plunger operating against a return spring of which the tension is so adjusted as to overcome the pull of the solenoid at about 85 percent of full motor load but to permit the solenoid plunger to be drawn in when the motor current passes that giving rated horsepower, thereby opening the circuit of the electromagnetic vibrator of the feed table and so stopping the feeding of grain to the grinder. Both capacitor and repulsion-induction motors in the  $\frac{1}{2}$ - and 1-hp. sizes have a  $\frac{3}{4}$ - to 2-a. current increase between 75- and 125-percent loads, and the solenoid control operates on a total differential of  $\frac{1}{4}$  a. It is believed that this controller is best suited for mills of 1 hp. or less, or when the grinder is to be used exclusively for grinding shelled corn or small grain.

**Drying artificially heated wheat with unheated air, C. F. KELLY**. (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 9, pp. 316-320, figs. 6).—The experiments reported upon were designed to show relationships between initial temperatures and moisture contents of the wheat and the dry-bulb temperature, humidity, pressure, and outlet temperature of the drying air. Effects of variations in the depth of the wheat layer during drying and of other factors involved in the design of the drier are also considered. Experiments were made at initial temperatures of 121°, 137°, 147°, and 156° F., and with wheat depths in the drier of 6, 12, and 24 in. Data which may be used either for designing or selecting the best operating conditions for driers already constructed are given in tables and charts.

**Relation of agronomic and nutritional factors to engineering problems and farm practices in making grass silage, T. E. WOODWARD**. (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 2, pp. 54-56, fig. 1).—The author points out as advantages of conversion of grass and some crop residues into silage that waste through the refusal of cattle to eat the coarser parts of the dried material is entirely eliminated, and that when weather conditions render the making of good hay impossible converting the grass into silage will conserve nutrients lost when only poor hay can be made. Grass and legume silage will be advantageous in regions where considerable quantities of poor hay are produced but not in regions where hay is uniformly good. An essential for the production of mold-free silage is the elimination and exclusion of air by chopping fine, weighting down with 2 or 3 ft. of green material at the top of the silo, and making the

walls and doors of the silo airtight. It was found that moisture in excess of 68 percent creates a danger of loss by leakage, subjects the silo to unnecessary lateral pressure, and produces silage of lower palatability and nutrient content. Making the silo wall impervious to air by painting with asphalt dissolved in gasoline prevented mold. Desirable engineering improvements are field choppers that will pick up and chop material either by mowing it or by taking it from the windrow at will; a bucket-type elevator to eliminate the blower pipe clogging, caused by finely chopped crops and crops wet with external moisture; and means for draining the excess juice so that it will not seep through the walls of the silo. A discussion by G. R. Shier is appended.

**Observations on the storage of grass silage, H. E. BESLEY and J. R. McCALMONT.** (N. J. Expt. Stas. and U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 2, pp. 51-53, figs. 4).—Foundation drains showed promise of giving satisfactory operation, particularly when pressures are not excessive. Vertical joint leakage from concrete-stave silos may be controlled to some extent by prestressing the hoops, but joints must be redesigned or provided with seals before general satisfaction can be expected. Results of the New Jersey tests on coatings for concrete were found not at all promising. Other observations seemed to indicate that varnishes and synthetic resin with wood-oil vehicles, asphalts, coal tars, and portland-cement washes will probably give some satisfaction. In choosing an asphalt or coal-tar preparation, care should be taken to select one that has a high melting point in order to minimize sticking of the silage. Silos should be adequately reinforced. Silos with exposed reinforcing are likely to be more satisfactory for storing high-moisture silage than those with reinforcing concealed in the mortar joint because of the likelihood of the mortar failing and leaving the steel exposed to the action of the silage acids. Exposed reinforcing can also be prestressed, thereby lessening the tendency for cracks to open in the walls. It can be inspected at will, and repairs or replacements can easily be made when necessary. Under usual farm conditions silos of average size will hold about the same tonnage of grass as of corn.

**Equipment, methods, and costs of collecting farm crop residues, R. B. GRAY.** (U. S. D. A.). (*Agr. Engin.*, 22 (1941), No. 2, pp. 57-58).—The author suggests sets of specifications for moisture, chaff and dirt, and weed contents, for baling and bale size for straw to be delivered to strawboard manufacturers, and for cornstalks to be delivered to the processors, the latter specification including maxima for moisture content, leafy material, kernels, and dirt. Cost data concerning gathering of straw and stalks and five possible schemes for cutting and baling straw are discussed.

**Equipment, methods, and costs of collecting corn stalks, J. B. DAVIDSON.** (Iowa Expt. Sta.). (*Agr. Engin.*, 22 (1941), No. 2, p. 68).—The author points out that the development of cornstalks as a raw material for the manufacture of paper, strawboard, and the like is impeded by the high cost (from \$8 to \$10 per ton) at the factory and the low return to the corn grower. An approximate cost distribution on the basis of \$10 per ton at the factory is given, and points of attack to be considered in an effort to reduce the total cost and increase the return to the farmer are indicated. Baling is especially noted as an expensive operation which might be replaced by chopping if the stalks were to be delivered to a factory nearby. It is also pointed out that the more palatable portions of the stalks, useful as a feed but of little value for manufacturing purposes, might be separated from the industrially valuable coarser portions and retained for farm use. Collecting the stalks at the time of picking or field shelling might also be tried out.

**The purchase of fencing on specification, S. A. BRALEY** (*Agr. Engin.*, 22 (1941), No. 2, pp. 49, 50, fig. 1).—The two factors emphasized as of greatest importance in the corrosion resistance of galvanized wire are the resistance to cracking of the zinc coating on wrapping or twisting the wire about itself in forming end loops and the weight of the uniformly distributed coating. It is noted that the alloy composition of the base metal has a great influence on the adherence of the coating and that maximum corrosion resistance in the base metal itself is very important, the presence of from 0.2 to 0.3 percent of copper in the steel wire adding materially to its corrosion resistance. Though farm fence is not usually manufactured to A. S. T. M. specifications, the purchaser can look for the heaviest coating obtainable for equal or slightly greater cost, and thereby obtain an increase in the life of the protective coating entirely out of proportion to the slightly increased cost. The author's criteria are summed up in the four questions: Does the base metal of the fence have the greatest corrosion resistance, once the protective zinc coat has corroded away? Is the base metal of such composition that the zinc adheres sufficiently so that normal distortion of the wire during fabrication does not cause it to crack and peel? Is the amount of zinc on the wire the most that can be obtained without excessive extra cost? Will the fence maintain approximately the same lustrous finish that it has when purchased?

**The electric fence, C. F. DALZIEL and J. R. BURCH**, (Univ. Calif.). (*Agr. Engin.*, 22 (1941), No. 11, pp. 399-406, figs. 9).—From a detailed study of the characteristics and performance of a number of types of electric fence designs, the authors conclude that it is impossible to design an electric fence controller which will be safe for all individuals. The noninterrupted A. C. electric fence with a current limitation of 8 ma. is believed dangerous. The noninterrupted D. C. fence with a current limitation of 15 ma. is believed reasonably safe. The intermittent types of electric fence controllers as approved in present regulations, although possibly safe electrically, should be considered inhumane. The single impulse electric fence controller is believed to be a satisfactory and reasonably safe solution of the electric fencing problem. The shock hazard from the charge on the average 10- to 15-mile electric fence wire is believed small.

**Radiation in agriculture, J. P. DITCHMAN** (*Agr. Engin.*, 22 (1941), No. 11, pp. 389-390, figs. 2).—The author briefly discusses the radiant energy output of various types of filament and vapor arc and other gaseous discharge lamps, the use of the infrared radiations for brooder warming, crop dehydration, and other heat treatment and of the ultraviolet for irradiation and sterilization, and the nature and some operating characteristics of a new short-tube, small-bore, high-pressure mercury vapor arc consuming 1,000 w. in the lamp proper and requiring cooling by water or other circulating liquid. The cooling liquid may be milk or other liquid requiring irradiation for sterilization or for vitamin D production. Tables of percentage of the over-all input radiated in various wavelength bands in the ultraviolet, visible, and infrared ranges for various sodium vapor, mercury vapor, fluorescent, and filament lamps are included, together with percentages of solar energy in similar bands at the earth's surface at Washington, D. C.

**Effect of short-wave irradiation on farm animals, T. E. HIGHTON**. (Ind. Expt. Sta.). (*Agr. Engin.*, 22 (1941), No. 2, pp. 47-48).—This is a brief review of work on the ultraviolet irradiation of poultry and cattle. Some results of poultry irradiation by means of 250-w. CX lamps are mentioned. It is noted that the irradiation from these CX lamps contains only from 1 to 7 percent as much of the highly effective mercury-arc wavelengths 280.4 and 296.7 m $\mu$  as does that from the 100-w. S-4 lamp.

**New electric lamp brooder, D. C. KENNARD and V. D. CHAMBERLIN** (*Ohio Sta. Spec. Cir. 63 (1942), pp. 7, figs. 4*).—This brooder consists essentially of a 4- by 4-ft. top and 1-ft. sides made from a 4- by 8-ft. piece of  $\frac{1}{4}$ -in. plywood or sheet of  $\frac{1}{8}$ -in. hard fiberboard, top and sides being nailed to 1- by 1-in. cleats so that the sides project 4 in. above the top to provide space for litter-insulation material, the whole supported on four 16-in. legs  $1\frac{1}{2}$  by  $1\frac{1}{2}$  in. and heated by one 150-w. reflector-type flood lamp and one 250-w. drying lamp. It was found unnecessary to provide either thermostatic control or mechanical ventilation. Side curtains were used only when the behavior of the chicks indicated draft. When curtains were needed, strips cut from feed bags and made 4 ft. by 8 in. were satisfactory. These brooders have proved effective in extensive use throughout the year under widely varying conditions.

**Heating studies of an outdoor brooder, J. B. GREINER.** (U. S. D. A.). (*Agr. Engin., 22 (1941), No. 11, pp. 391-392, figs. 2*).—A group of 14 brooders, 2 heated by kerosene lamps and the remaining 12 by a variety of electric units variously insulated, were subjected to 4 series of tests, 1939-41. All of the brooders were of inexpensive construction. Modifications of design found necessary for convenience or efficiency included changing from bimetallic to wafer and snap-action, switch-type thermostats operated from outside the brooder. Among heating units discarded or changed were the bowl-type radiant heaters and heating coils in the shrouded air passage in the rear of the brooding compartment. In the final series of tests the brooders heated by 250-w. reflector drying lamps were first and second in economy of electricity consumed per unit, and a non-fan-equipped commercial package unit was third in economy. Two of the fan-equipped units were fourth and fifth in economy. Throughout these tests the brooders heated by kerosene oil lamps as checks have been more economical when costs of electricity and oil are compared. Electricity was cleaner and more convenient, however, and lowered the labor requirements.

**Citrus growers profit by refrigeration research** (*U. S. Dept. Agr., Bur. Plant Indus. Rpt., 1941, p. 22*).—A 50-percent increase in the number of orange boxes per car having necessitated special fan equipment, car wheel-driven fans were placed in several hundred cars and were found more effective at normally low temperatures and during much of the season than was car icing alone.

**How to obtain adequate farm housing with limited income, D. G. CARTER** (*Agr. Engin., 22 (1941), No. 9, pp. 309-310*).—Much of this housing must be done with noncommercial grades of material and cash outlays of less than \$500. In 200 cases studied the author found that the farm was able to contribute an average of about 75 percent of the labor and sufficient materials to make the noncash contribution equal to slightly more than one-half the total house value. The average income of the families included in the study was about \$700 (median, about \$500). The typical cash expenditure was approximately equal to 1 year's income, and the resulting house value was \$1,500 (median, \$1,300). There are approximately 2,000,000 farm families in the lower one-third by income classification, the average housing condition within this group being substandard and the need for improvement critical. If a program of "self-help" in labor, materials, and technical aid can be developed, housing can be attained by a large number of families. In every case there will be some cash expenditure for materials, probably averaging \$500. or more per unit. This cash expenditure will be utilized for the materials that afford a higher standard of quality, rather than for the rough or bulk materials.

**Balancing farm structures with farm capabilities, J. A. SLIPPER.** (Ohio State Univ.). (*Agr. Engin., 22 (1941), No. 9, pp. 311-312*).—This paper considers only functional structures, living quarters being left aside. As the basis for

determining what and how much functional structure is optimal, the author proposes to start from the productivity indexes when available, since maximum productive capacity of the soil is a fundamental fixed point. From the productivity index "we may calculate (1) the volume and weight of each harvested crop to be stored if the cropping program were conducted at the 'normal' or at the 'attainable' level, and (2) the number and kind of livestock that these crops as feed will support and that the structures are to accommodate." In addition to the space and strength requirements thus indicated, the necessary degree of stabilization of temperature and humidity and of dust control must also be known and provision for advantageous use of the required labor must be made. The paper is an analysis of the broad fundamentals of the problem and is not concerned with structural designing per se, with materials, or with building costs, but rather with the "duties of a structure to the enterprises of which it is an organic, functional part."

**Farm buildings—tombstones or tools**, D. H. DOANE (*Agr. Engin.*, 22 (1941), No. 9, pp. 313-315).—The author stresses the viewpoint that farm buildings should be planned rather for use value than for extreme permanence. A structure built to outlive its usefulness violates the principle that there should be minimum obsolescence value left to throw away at the end of the useful life of the building.

**Fireplaces and chimneys**, A. H. SENNER and T. A. H. MILLER (*U. S. Dept. Agr., Farmers' Bul.* 1889 (1941), pp. [2]+52, figs. 44).—This supersedes Farmers' Bulletin 1649 (*E. S. R.*, 64, p. 686). It first takes up chimney design, construction, and cleaning and repairing flues in considerable detail. Fireplaces of both indoor and outdoor types are then discussed, the indoor constructions dealt with including such modified fireplaces as the Franklin stove and designs providing for circulation of air from the room through ducts heated by the fire, with return to the room through grilles or registers above the fireplace. Beauty and appropriateness of design are considered, as well as safety, effectiveness, and convenience.

**Watch your step: Farm safety for national defense**, W. BRINK (*U. S. Dept. Agr., Misc. Pub.* 481 (1942), pp. 32, figs. 9).—Possible causes of accident or injury likely to be found in buildings, farm machines, electrical equipment, gasoline and other inflammable materials, home appliances, and farm animals are pointed out. Causes of fires, fire prevention, and provision of adequate fire-fighting facilities are among the subjects especially stressed, as are the numerous causes of minor and major personal injuries. Preventive or protective measures are suggested wherever practicable. Figures showing agriculture to be the most hazardous occupation are graphically presented.

## AGRICULTURAL ECONOMICS

[**War problems in agricultural economics**] (*U. S. Dept. Agr., Sec. Agr. Rpt.*, 1941, pp. 1-24, 27-65, 79-117, 121-155, 166-175, 182-195, 220-222, 237-239).—This report to the President of the United States describes the wartime task of the Department and of agriculture. The phases applying more or less definitely to agricultural economics and not noted elsewhere are discussed in sections as follows: Impact of war and defense effort on agriculture, price conditions and farm-price policy, our farm exports in wartime, commodity agreements among nations, food situation in Europe, our cooperation with Latin America, preparing post-war foreign-trade policy, agriculture's requirements for defense production, organization to handle the Department's defense relations, special defense functions in the Department, locating defense industries and military and

naval reservations, the wartime job of the A. A. A., the commodity loans, farm conditions in 1941, the year's production, the cotton problem, handling the wheat surplus, sugar supplies for American consumers, wartime changes in the tobacco situation, fruits and vegetables, the defense response in livestock products, poultry and eggs for defense, dairy production for defense and lend-lease shipment, pressure on storage facilities, lend-lease buying and surplus distribution, crop insurance, our changing crop map, preparing for the impact of peace, agriculture in post-war readjustment, the shelf of projects, agricultural planning, reports of State committees on farm requirements, hired labor in agriculture, evolution of our land policy, land legislation of State governments, shortage of farms to rent, land values and land speculation, farm credit problems, marketing facilities and methods, agricultural aspects of current irrigation problems, and the commodity exchanges.

**Report of the Chief of the Bureau of Agricultural Economics, 1941, H. R. TOLLEY** (*U. S. Dept. Agr., Bur. Agr. Econ. Rpt., 1941, pp. 51*).—This report to the Secretary of Agriculture for the year ended June 30, 1941, describes and discusses the activities of the Bureau under the following headings: A democracy uses its experts in a time of crisis, blending research and planning into programs for action, unifying policies through interbureau cooperation, and focusing Bureau of Agricultural Economics activities on farmers' local problems.

Appendixes include tabular examples of the year's work of the Bureau and a list of publications issued during the year.

**[Investigations in agricultural economics at the Georgia Station].** (Partly coop. U. S. D. A.). (*Georgia Sta. Rpt. 1941, pp. 8-15, fig. 1*).—Included are brief descriptions of farm management studies in Greene and Gwinnett Counties, a study of 10 of 12 farmer wholesale fruit and vegetable markets of the State, and a study of the 1940 cotton ginnings of the State. Some brief general findings are given for each study. A map shows the types of tenancy areas of the State. The principal characteristics of each area are described.

**Farm income [studies in Wisconsin].** (Partly coop. U. S. D. A.). (*Wisconsin Sta. Bul. 453 (1941), pp. 34-45, 46-47, figs. 3*).—A discussion of county management of tax-delinquent land, by G. Wehrwein and P. Raup; changes in livestock markets, by M. A. Schaars and A. Hobson; southern dairy competition, by W. P. Mortenson and Schaars; how to select the better-paying and most productive farms, by P. E. McNall and D. Anderson; milk production with little grain, by H. O. Anderson and McNall; badly eroded areas call for drastic changes, by McNall, L. A. Salter, and H. O. Anderson; and returns from farm wood lots, by H. O. Anderson, D. Keyes, and McNall.

**Incoming and outgoing payments of Iowa farm families, L. WITT** (*Iowa Sta. Res. Bul. 293 (1941), pp. 409-472, fig. 1*).—"This study has two major purposes: (1) To develop technics for estimating the income-expenditure patterns of farm families over a period of years, and (2) to apply these technics in constructing an income-expenditure pattern for Iowa farm families during a major business cycle." A table shows by the years 1929-39 (1) the incoming payments to Iowa farm families from agricultural products and from off-farm wages; (2) the outgoing payments for rent, feeder stock, wages, seeds, limestone and fertilizer, twine, gasoline, oil and grease, baby chicks, machinery, buildings and repairs, taxes, short-term interest, long-term interest, telephone, electricity, farm organization, consumption, and sales tax; and (3) the short- and long-term capital adjustments. Another table shows the payments made by families as ratios of the expenditures for the same items in 1929, and a third table shows the payments as ratios of the total incoming payments in the same year. The greater part of the bulletin is devoted to a description of the pro-

cedure used in developing each series of estimates. The estimates of income and expenditures cover almost a complete major business cycle and include nearly all income and 80 percent or more of the expenditures.

"Incoming money payments of Iowa farmers in 1932 were only 38 percent of the 1929 level. By 1939, they had increased to 88 percent of 1929. With the sharp drop in income in 1931 and 1932 farmers also reduced expenditures but since 1933 have increased them. Expenditures were reduced far more for some items than for others. Expenditures for fertilizer, machinery, and buildings in 1932 were about 20 percent of those for 1929, while expenditures for taxes, gasoline, telephones, and electricity had dropped only to about 75 percent of those for 1929. Tax and interest payments remained relatively high until 1931, when they dropped sharply as the full impact of the depression hit Iowa agriculture. With higher incomes after 1933, farmers increased some expenditures but not others. In 1939 more was spent for feeder livestock, seeds, gasoline, baby chicks, electricity, and farm living than in 1929, even though income was 12 percent less. This was possible through smaller increases in other expenditures, particularly taxes, buildings, wages to hired labor, and interest on indebtedness, all of which were less than two-thirds of 1929 levels. In recent years the homestead exemption law has reduced expenditures for taxes, while foreclosures, revaluations, and bankruptcies have wiped out much of the interest charges. Heavy expenditures for machinery were made in the last few years, the number of farms served by electricity more than doubled from 1929 to 1939, more gasoline was used for power, and more chicks were purchased from hatcheries. Farm-family living and rent together make up nearly half of the total expenditures of Iowa farmers. Both items showed considerable flexibility over the business cycle, though not as much as income. In 1939 they were as large as in 1929 and hence were a larger part of the total income. There were, of course, more tenants in 1939. The combination of factors as portrayed by expenditures shows sharp contrasts in 1939 compared to 1929, and with it have gone shifts in demand for various factors of production. Clearly Iowa agriculture is continually changing in character."

**The significance of reported trends in Louisiana agriculture**, T. L. SMITH (La. State Univ.). (*Southwest. Social Sci. Quart.*, 22 (1941), No. 3, pp. 233-241).—The author calls attention to some interpretations of Louisiana census data, the principal one being the reporting of areas tilled by sharecroppers as farms. He concludes that "only farm owners, farm managers, and farm renters should be included in the category of farm operators. The farm 'tenant' who cannot qualify as a renter (standing, share, or cash) should be relegated to the category of farm laborers. The land worked by him should not be counted as a farm."

**Farm management in Newberry County, South Carolina**, M. J. PETERSON and J. D. KINARD (*South Carolina Sta. Bul.* 338 (1942), pp. 31, figs. 3).—Data covering the entire farm business of 101 farms were collected early in 1940 for the crop year just ended. The physical and economic conditions of the county, land use, fertility maintenance, number of livestock, etc., are described. Analysis is made of the receipts, expenses, and income of farms and factors affecting income—combination of enterprises, size of business, labor efficiency, rates of production, distribution of farm capital, and education of the operator.

"Some of the outstanding features of the successful farms in Newberry County were good balance of enterprises, relatively high labor efficiency, adequate size of business, rates of production of both crops and livestock above the average, and effective distribution of the capital invested in the farm business. Where the physical factors permit and the operator's management ability is adapted,

it appears that the most profitable combination of enterprises is to have livestock, such as dairy cattle, hogs, or poultry, combined with cotton. This type of farming resulted in the largest business, greater efficiency of labor, and provided a distribution of income throughout the year."

**A method of estimating the economic effects of planned conservation on an individual farm**, A. C. BUNCE and G. W. COLLIER. (Coop. Iowa Expt. Sta.) (*U. S. Dept. Agr., Misc. Pub. 463* (1942), pp. 28).—"This publication outlines some factors that should be considered and some estimates that should be made in order to determine the probable economic effects of adopting a specific plan of erosion control." It presents a method of making the estimates that may be used by farmers in evaluating the implications of alternate farm plans upon farm income. The method is discussed and illustrated by use of a farm that had adopted a program of soil conservation. No attempt is made to evaluate separately the effect of specific erosion control measures. The subject is discussed under the following headings: Changes in crop production, effect of changes in crop production on the livestock system and farm income, effect of changes in crop production and livestock on the use of labor, cost of achieving control of erosion, estimated capital loss resulting from soil erosion, and the final balance.

**A bibliography on the agriculture of the American Indians**, E. E. EDWARDS and W. D. RASMUSSEN (*U. S. Dept. Agr., Misc. Pub. 447* (1942), pp. V+107).—Annotated items included are grouped under the following headings and subheadings: Comprehensive histories; agriculture of the American Indians, including comprehensive references, agriculture of particular regions and tribes, specific crops and animals, and agriculture on Indian reservations in the United States; and uncultivated plants used by the American Indians, including food and industrial plants and medicinal plants.

**Agricultural production in New York, 1866 to 1940**, T. E. LAMONT ([*New York*] *Cornell Sta. Bul. 769* (1941), pp. 36, figs. 27).—This is a revision of Bulletin 693, *Agricultural Production in New York, 1866 to 1937* (E. S. R., 80, p. 124).

**Foreign Agriculture, [January 1942]** (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr.*, 6 (1942), No. 1, pp. 42, figs. 5).—Included are the following articles: Sweden Adjusts Its Agriculture to War Conditions, by E. Aberg (pp. 3-14); Wartime Agriculture and Post-War Objectives, by M. Ogdon (pp. 15-32); and Food Consumption in the United Kingdom, by J. H. Richter (pp. 33-42).

**Corporate-owned farm land in Minnesota, 1936-1940**, A. A. DOWELL (*Minnesota Sta. Bul. 357* (1942), pp. 24, figs. 13).—The data as to farm real estate held by rural corporations other than the Minnesota Department of Rural Credit were obtained from the files and publications of the Minnesota Agricultural Conservation Committee of the U. S. D. A. Agricultural Adjustment Administration. In the analysis the farms were segregated into the following groups on the basis of corporate type: (1) Federal Land Bank and Federal Farm Mortgage Corporation, (2) Minnesota Department of Rural Credit, (3) joint stock land banks, (4) insurance companies, (5) open and closed banks, (6) trust and mortgage investment companies, (7) educational, religious, and fraternal organizations, and (8) other corporate agencies. The extent of holdings, the variations by type-of-farming areas and by counties, and the holdings by the different types of agencies are analyzed and discussed. The factors responsible for corporate holdings—land values, prices of farm products, crop yields, and price relationships—the disposal of corporate-owned farms, and the trends in corporate holdings are discussed and described.

The percentage of all farm lands owned by corporate agencies increased from 9.1 percent on January 1, 1936, to 10.4 percent on January 1, 1938, and then declined to 9.9 percent on January 1, 1940. On January 1, 1940, the holdings in the different counties varied from 0.5 percent to 30.9 percent of all land in farms. Life insurance companies owned more land than any other type of corporation. The Minnesota Department of Rural Credit ranked second. Corporate holdings tended to be high in areas where land prices declined most severely prior to acquisition and to be relatively low in areas where the least relative decline had occurred. There was some tendency for corporate holdings to be relatively low in high land value areas and relatively high in low land value areas.

**Farm tenancy in California and methods of leasing, R. L. ADAMS and W. H. SMITH, JR. (*California Sta. Bul. 655 (1941), pp. 119, figs. 5*).**—"The purposes of this publication . . . are to (1) indicate the extent and trend of farm tenancy in California, (2) point out the usefulness or utility of the practice of leasing, (3) suggest a basis for determining an equitable division of farm income between landlord and tenant, (4) suggest certain items to be considered in drawing up farm leases, and (5) describe leasing methods and practices commonly followed in various sections of California." The method used in the study was largely of a survey nature and much of the analysis is of a descriptive nature. The sections dealing with extent, trends, and distribution of farm tenancy in the State are based largely on reports of the U. S. Bureau of the Census. Those on the utility of farm tenancy, the rental basis, and California leasing practices are based largely on data obtained in field surveys. The most important sources of these data were records of county agricultural conservation associations, the Agricultural Extension Service, banks, loan companies, land companies, buyers of crop and livestock products, etc. These data were supplemented by questionnaires, correspondence, and interviews with over 350 farmers and livestock men. The section dealing with Federal legislation affecting leasing practices in the State is based entirely upon published material of the U. S. D. A. Agricultural Adjustment Administration, supplemented by correspondence with officials of that organization. The section on California farm leasing practices was based on data obtained from 4,377 farm leases and supplementary field investigations in the more important agricultural sections of the State.

**The nature and extent of farm tax delinquency in South Carolina, G. H. AULL (*South Carolina Sta. Bul. 337 (1941), pp. 31, figs. 4*).**—Data were obtained by trained WPA workers from the county records of all but two counties of the State regarding the ownership and location of each piece of farm property delinquent during the period 1933-37, the acreage and assessed value involved, the amount of taxes levied, and the date of subsequent payment, if any, of the taxes. Using these data and those obtained in a study of farm real estate tax delinquency during the period 1928-32, a study is made of the trends in delinquency as shown by the number of properties and acres delinquent and the total amount of delinquent taxes. Using the data for the 1933-37 period, the frequency of delinquency, the geographic distribution of delinquency in 1937, the characteristics—ownership, size, assessed value, and taxes levied—of delinquent and nondelinquent properties, and the current status of delinquent properties, are analyzed and discussed.

"The study indicates that delinquency has become chronic in the case of many farms and is acute at some time or other on three out of every four of those listed for taxation. The average farm property in the State is delinquent once every 2 yr. Approximately 20 percent of the properties which became delinquent were found in the delinquent column every year, and delinquencies of 1 yr. only occurred in less than one-third of the cases examined."

Approximately 25-30 percent of the taxes becoming delinquent remained unpaid after 5 yr. "For the most part delinquency occurs relatively more frequently on individually owned (as contrasted with corporate-owned) properties, which are of less than average size and of low absolute assessed value. The data suggest, however, that from the standpoint of actual value, delinquent properties are regularly over-assessed—this in spite of the fact that assessments on delinquent properties have been reduced more rapidly in recent years than assessments on other properties. These reductions, however, have been offset in part by higher rates of taxation on delinquent than on nondelinquent properties."

**Annual Report of the Manager of the Federal Crop Insurance Corporation, 1941, L. K. SMITH** (*U. S. Dept. Agr., Fed. Crop Ins. Corp. Rpt., 1941, pp. 25*).—This report to the Secretary of Agriculture for the fiscal year ended June 30, 1941, "consists of an analysis of the Corporation's activities, an examination of the problems we met and our solution of them, and an explanation of improvements incorporated in next year's program."

**Report of the Chief of the Agricultural Marketing Service, 1941, C. W. KITCHEN** (*U. S. Dept. Agr., Agr. Market. Serv. Rpt., 1941, pp. 55*).—This report to the Secretary of Agriculture for the year ended June 30, 1941, covers the work of the Service on agricultural statistics; the market news; standards for farm products; inspection, grading, and classification; and regulatory work.

**Report of the Chief of the Commodity Exchange Administration, 1941, J. M. MEHL** (*U. S. Dept. Agr., Commod. Exch. Admin. Rpt., 1941, pp. 45*).—This report to the Secretary of Agriculture for the fiscal year ended June 30, 1941, discusses the futures markets under the defense program and the general regulatory activities of the Administration. The futures activities in different grains, cotton, wool tops, fats and oils, butter, eggs, potatoes, and different feedstuffs are discussed.

**Report of the Administrator of the Surplus Marketing Administration, 1941, R. F. HENDRICKSON** (*U. S. Dept. Agr., Surplus Market. Admin. Rpt., 1941, pp. 46*).—This report to the Secretary of Agriculture for the fiscal year ended June 30, 1941, discusses the activities of the Administration under the following headings: Agricultural marketing and distribution programs today, the marketing agreement programs, domestic distribution programs, dealing with specific agricultural marketing problems, and agricultural transportation cases and actions.

The local structure of milk prices in New Hampshire markets, **A. MAC-LEON** (*New Hampshire Sta. Bul. 332 (1941), pp. 60, figs. 13*).—The historical background of milk prices in New Hampshire is sketched briefly. Analysis is made of the prices received at the farm by producers in a typical market (Nashua, N. H.), of producers' prices at varying distances from the market, and of individual producer's prices received within a given distance from the market. The price relationships between different markets of the State are studied. With a view to ascertaining producers' responses to prices, detailed studies were made in the Haverhill and Jefferson areas. In the first area the Boston, Mass., and Manchester, N. H., markets are in competition, and in the second area the Boston and Berlin, N. H., markets. In each case, following a brief historical statement of the price relationships between the Boston and the other market, the factors other than price influencing producers in the choice of a market and the market response of the producers are analyzed and discussed.

The study of the Nashua market showed that prices to producers are not arrived at through any scientific basis and are not those which would be

brought about by perfectly competitive conditions. Between markets of the State, prices varied much more widely than the difference in transportation charges would justify. The factors affecting the market response of producers to varying prices of milk are so many and so varied that no generalizations are possible as to the findings reported.

**Egg marketing in the Los Angeles area**, H. E. ERDMAN, G. B. ALCORN, and A. T. MACE (*California Sta. Bul.* 656 (1941), pp. 91, figs. 30).—This represents an attempt to ascertain how the Los Angeles egg market works. Studies were made (1) of the way the southern California market is organized to move eggs from producer to consumer, and of the sorts of agencies that handle eggs, the services they perform, and the nature of the competition between them; (2) of the way in which prices are determined, the nature of the price structure, and the way market prices are reported in the Los Angeles market and in certain other markets; (3) of the rate at which quality of eggs declined under conditions somewhat similar to those under which eggs move through the trade channels; (4) of the movement of eggs into and out of the Los Angeles market area and of the way the Los Angeles market is constantly adjusting itself to other markets in the United States; and (5) of the marketing methods found useful in certain other regions to ascertain their adaptability to southern California.

Four different procedures were used. First, representatives of a large number of firms in the egg business were interviewed. Second, price and movement data compiled from State and Federal market news reports were analyzed. Third, several lots of eggs purchased from producers were candled and broken to ascertain interior quality. Fourth, other marketing systems reported in publications and in correspondence with the authors were studied.

What may be done to improve conditions in the Los Angeles market is discussed. Some suggestions are made as to means that might be used to improve the position of poultry producers.

**Washington apples on the New York and Chicago fruit auctions**, M. T. BUCHANAN (*Washington Sta. Bul.* 401 (1941), pp. 55, figs. 13).—Analysis is made of the volume and prices of Washington apples on the two auctions during the marketing seasons, 1928-29 through 1939-40. The quantities and prices of different varieties, grades, and sizes of apples and the seasonal sales of important varieties are examined and comparisons made between the two markets. For the New York auction comparisons are also made between the important production areas of Washington. The study was based mainly on data obtained from New York Daily Fruit Reporter and from the Chicago Fruit and Vegetable Reporter. Tabulations and data of the U. S. D. A. Bureau of Agricultural Economics and Agricultural Marketing Service, the Washington State Department of Agriculture, and previous studies of the experiment station were also used. In the study of prices, analysis was made for each auction of the differentials for variety, grade, and size.

For the 12 marketing seasons studied the proportion of the annual commercial production of the State sold in the Chicago auction varied from 2.1 to 4.5 percent, averaging 3.6; that on the New York auction from 6.2 to 11.6 percent, averaging 8.6; and that for the two auctions combined from 10.5 to 14.8 percent, averaging 12.2 percent. During the latter part of the period there was a shift from the New York to the Chicago auction in the proportion of apples marketed.

Delicious is the most important variety grown in Washington. Prices of standard Delicious declined rapidly during the period studied relative to the prices of other varieties, and in the later years Winesap and Yellow Newtown apples returned about the same money as Delicious. There was a tendency toward

sales of fewer varieties. In general, medium-sized apples sold for the highest price. Grade as a factor affecting price had about the same effect on both auctions. The highest grade differentials were for Delicious and the next highest for Rome Beauty. The differential was higher for Jonathans on the Chicago auction and for Yellow Newtowns on the New York auction. There was less difference between the prices of different grades of apples when prices were low than when high.

**The marketing of Washington apples in Los Angeles, California—Part I, Transportation and wholesale distribution,** M. T. BUCHANAN and E. F. DUMMEIER (*Washington Sta. Bul.* 406 (1941), pp. 51, figs. 3).—This is the first of a series of reports analyzing information obtained in a survey conducted during December 1940 to February 1941 of apple marketing in Los Angeles. This report is based mainly on information obtained from railway agents, the Wenatchee Valley and Yakima traffic associations, the U. S. D. A. Agricultural Marketing Service, 30 truckers, 8 brokers, 28 jobbers, and 10 chain store organization headquarters. The methods of transportation, transportation rates, and the comparative advantages of truck and rail transportation are described. The channels of wholesale distribution, point of sale, packs and packages used, condition of apples in the hands of jobbers, brands and advertising and jobber margins, brokerage fees, and other costs of wholesale distribution are discussed. A general discussion of the Washington apple deal includes discussions of "illegitimate marketing," size of apples, prices, competition of Canadian apples, the need of a central marketing agency, storage, and the advantages and disadvantages of the sale of C grade apples.

During 1939 and 1940 approximately 60 percent of all Washington apples sent to Los Angeles were transported by motor trucks. The most important channel of distribution of apples on the Los Angeles market was the packer-shipper, broker, jobber, retailer channel. The total charges per box in January 1941 for transportation and wholesale distribution of Extra Fancy Jonathan apples sold by jobbers to retailers at \$1.87 per box were: Transportation 30 ct., jobber margin 12 percent (22 ct.), and brokerage fee 5 ct. per box.

**The world wheat situation, 1940-41: A review of the crop year,** H. C. FARNSWORTH (*Wheat Studies, Food Res. Inst. [Stanford Univ.],* 18 (1941), No. 4, pp. [2] + 109-190, figs. 18).—War influenced every phase of the wheat situation in 1940-41. It resulted in artificial shortage of wheat in continental Europe and in reduced consumption there. It restricted wheat exports and augmented the wheat surplus carried by the overseas exporting countries. It stimulated many governments to assume full or partial control over wheat supplies, distribution, and prices. Britain's tightened naval blockade in the Atlantic kept overseas wheat from going to the Axis area of the Continent. The overseas exporting countries continued to struggle with the problem of surplus wheat stocks. Australia alone was little troubled, since she had suffered a virtual crop failure in 1940.

**Crops and Markets, [December 1941]** (*U. S. Dept. Agr., Crops and Markets*, 18 (1941), No. 12, pp. 269-328, figs. 4).—In addition to crop and market reports of the usual types, tables are included showing the acreages, yields per acre and production, total and by States, of different crops in 1940 and 1941 and the average 1930-39. A short article discusses the cost of producing field crops in 1940 and includes tables showing for corn, wheat, and oats the estimated costs of production in 1940 and the estimated cost per bushel on a 10-yr. average yield basis by groups of States, and for cotton the estimated cost of production by selected States and areas for 1940 and the estimated cost per pound of lint on a 10-yr. average yield basis.

## RURAL SOCIOLOGY

[Investigations in rural sociology] (*U. S. Dept. Agr., Sec. Agr. Rpt., 1941, pp. 24-27, 65-67, 155-164, 195-201*).—Rural life problems discussed in this report are farm and nonfarm population balance, migration in a defense period, our changing industrial map, coordinating farm with industrial trends, the impact of defense industries on rural communities, hired labor in agriculture, the long-range outlook for agricultural laborers, the post-defense farm-labor problem and the Department's responsibility, emergent groupings in the farm population, an analysis of agricultural census returns, migration and its problems, and aids to farm security, including increasing food production, experience gained in home-stead development, security for farm tenants, camps for migrant workers, medical care for farm families, helping those dispossessed from farms acquired by the Government for defense purposes, and defense employment for farmers.

[Rural organizations in Wisconsin], A. F. WILEDEN, F. H. FORSYTH, M. ANDERSON, M. KELLOGG, and D. VOERNHOLT. (Coop. U. S. D. A.). (*Wisconsin Sta. Bul. 453 (1941), p. 45*).—A sharp increase is reported in the number of clubs and other special interest organizations in rural Wisconsin during the past 15 yr. Most of the increase has come about in young people's clubs, which have tripled in number, and women's clubs, which have more than doubled.

Community land-use planning committees: Organization, leadership, and attitudes, Garrard County, Kentucky, 1939, H. W. BEERS, R. M. WILLIAMS, J. S. PAGE, and D. ENSMINGER. (Coop. U. S. D. A.). (*Kentucky Sta. Bul. 417 (1941), pp. 141-236, figs. 11*).—Rural people dwell together in neighborhoods and communities that do not necessarily coincide in extent with land-use areas, magisterial districts, voting precincts, postal routes, or school attendance areas. Yet boundaries of the 38 neighborhoods and 9 communities were determined in Garrard County by a relatively simple process of systematic observation described in Part 1.

Part 2 deals with the personnel and activity of the land-use planning community committees and part 3 with the opinions of committee members and non-members on the various questions investigated. In attitude and opinion, the committee member selections differed in general from their neighbors in a more general belief that land use is changing for the better, in more frequent adoption of land-conserving practices at home, in a more usual belief that conservation is profitable, in the thought that governmental agricultural programs have taught conservation, in the feeling that conservation practices would continue after a withdrawal of government payments, in the belief that education makes young people better farmers, in a generally favorable evaluation of extension work and county agent activity, in a relatively more favorable evaluation of the U. S. D. A. Agricultural Adjustment Administration program, and in the more consistent suggestion that rural living levels and rural satisfaction have become somewhat higher and greater during their generation.

After three years: A restudy of the social and economic adjustment of a group of drought migrants, P. H. LANDIS (*Washington Sta. Bul. 407 (1941), pp. 36*).—Continuing this study (*E. S. R., 82, p. 125*), the author concluded that measured by absolute average middle-class standards of living a large proportion of the migrants might be dubbed failures. Contrasted with their past situation in the northern Great Plains preceding their migration the group was making progress—were better satisfied with their present conditions than with their previous ones and planned to remain in the State. Between 1930 and 1940 the percent increase of population in the State of Washington was 11.1 compared with 7.0 percent increase for the United States as a whole.

**The resident laborer on the sugar cane farm, H. HOFFSOMMER.** (Coop. U. S. D. A.). (*Louisiana Sta. Bul. 334* (1941), pp. 50, figs. 3).—This continues work noted in Bulletin 320 (E. S. R., 84, p. 119).

More than 8 out of 10 of the 1,000 families (exclusive of owners and special workers) living on the 100 farms sampled had the tenure status of resident laborers. Of these, more than three-fourths were colored. A total of 328 families were interviewed, of whom 242 were resident laborers. Of these, 205 reported work during the planting and growing season at an average wage of 96 ct. per day. The average daily earnings for cutting cane were \$1.37. Roughly three-fourths of the resident laborer families reported a gross cash income for the past year, including the contributions of wives and children, of from \$250 to \$500. White families had slightly larger incomes than Negroes, though Negro family members contributed more than white family members. Eighty-one of the resident laborer families had children of from 10 to 15 yr. of age. Of these children, roughly one-half contributed to the family budget, with an average contribution of \$78. White and colored boys contributed with about the same relative frequency, but the colored boys contributed greater amounts. All of the girl contributors were colored.

Resident laborers moved rather infrequently, the average length of residence on the present farm being 13 yr. and the average number of farms lived on since working for themselves as apart from their parents being 2.5. The resident laborer belongs to a relatively fixed tenure class. Of 280 heads of families who started out as laborers, nearly 8 out of 10 still remained laborers. Eight out of every 10 resident laborers received as perquisites a house, garden space, wood, and a team for hauling the wood. Nine out of 10 of the resident laborers, croppers, and tenants received credit advances. Seven out of 10 of the tenants and croppers had glass windows in their houses, as compared with 3 out of 10 for the resident laborers. Two out of 10 of all houses had some screening. Among the houses for colored families, less than 1 out of 10 had screening.

The most commonly found laborer house consisted of two rooms, with three-, four-, and five-room houses next in order of frequency. Sharecropper and tenant houses averaged larger than laborer houses. Fourteen percent of the households reported ice boxes and phonographs, 5 percent radios, 4 percent electricity, and smaller percentages running water, bathtubs, telephone, and daily and weekly papers.

Church attendance was by far the most important formal community activity, more than 9 out of 10 of the tenants, croppers, and laborers stating that members of their families participated. More than 6 out of 10 of all families had members belonging to lodges. Less than 2 out of 10 reported members attending picture shows. Less than a third of the white and only 3 percent of the colored laborers reported attending dances.

**Some contrasts in women employed in two types of industries in Mississippi, D. DICKINS.** (Miss. Expt. Sta.). (*Social Forces*, 19 (1941), No. 4, pp. 522-532).—This report concerns the status of white women employed in five industrial plants of Mississippi (three cotton textile mills and two cotton garment plants), all located in poor agricultural areas of the State, and includes their ages, schooling and occupational experience, occupation of families in which reared, marital status and residence, number of children and care during mothers' working hours, housekeeping arrangements, home duties of housekeeping and nonhousekeeping women, and difference in women in the two industries.

## FOODS—HUMAN NUTRITION

**The progress of nutrition knowledge** (*U. S. Dept. Agr., Sec. Agr. Rpt., 1941, pp. 71-79*).—This brief account points to practical implications of the work of the Bureau of Home Economics (*E. S. R., 86, pp. 700, 716*).

**The nutrition campaign** (*U. S. Dept. Agr., Sec. Agr. Rpt., 1941, pp. 67-71*).—This is a brief account of the part taken by the Department in formulating a food policy for the present emergency and in putting it into action.

**[Food and nutrition studies by the Georgia Station]** (*Georgia Sta. Rpt. 1941, pp. 125-128*).—This report (*E. S. R., 84, p. 122*) notes progress in the study of the effect of environmental conditions on the ascorbic acid and mineral content of turnip greens and the mineral content of cowpeas grown in two or three areas in the State, as part of the project on the composition of vegetables grown in the South carried on cooperatively with five other Southern States and the U. S. Department of Agriculture. Progress is also reported on work concerning factors affecting the ascorbic acid content of tomatoes, and factors influencing the utilization of calcium by the animal body, including data on the calcium oxalate content of New Zealand spinach.

**[Nutrition studies at the Wisconsin Station]** (*Wisconsin Sta. Bul. 453 (1941), pp. 24-31*).—This report of progress in studies, many of which have been reported elsewhere, on animal nutrition and food values summarizes findings indicating that animals may synthesize some vitamins (S. Black and C. A. Elvehjem); vitamin E keeps carotene from oxidizing (F. Quackenbush, R. P. Cox, H. Gottlieb, and H. Steenbock); ethanalamine intensifies kidney hemorrhage in rats (R. Johnson, C. R. Thompson, Quackenbush, and Steenbock); a fourth factor, in addition to linoleic acid, pyridoxin, and pantothenic acid, is necessary to cure rat acrodynia (Quackenbush, F. Kummerow, D. Anthony, and Steenbock); meat contains its share of vitamins (L. M. Henderson, J. M. McIntire, and Elvehjem); pantothenic acid is distributed in various natural sources (A. Earle, C. Peters, and F. Strong); phosphorus in milk is highly available to the animal (R. Bunkfeldt and Steenbock); a large part of the thiamin and nicotinic acid content of wheat is removed in the milling of white flour (L. J. Teply, Strong, and Elvehjem); 1-2 mg. of riboflavin daily is not enough to meet the human requirement (H. Parsons, M. Reynolds, B. Moore, D. Williams, Strong, and R. Feeney); egg white may bind more than one vitamin (Parsons, M. Johnson, and D. Anderson); hydrolysis improves the quality of soybean protein (Parsons and C. Walliker); and "salty soys" prepared by soaking the soybeans before deep-fat frying are a good source of protein in the human diet (Reynolds, M. Primrose, and M. Rohde).

**Food composition tables**, H. R. MARSTON and M. C. DAWBAEN (*Austral. Council Sci. and Indus. Res. Pam. 107 (1941), pp. 36, figs. 3*).—This compilation, prepared in response to the request for information as to the composition of foodstuffs suitable for use in army rations, was based on data from a large number of original scientific communications, the values having been selected with due consideration of the methods employed for the chemical analyses and for the bio-assays utilized in the assessment of the various constituents. In the case of the vitamin data in particular, "only those assays which have been conducted by methods which are reasonably capable of yielding reliable data have been accepted." These methods are outlined briefly. The graph for the composition of beef was drawn up from information from American sources, but the similar graph for the assessment of the composition of mutton was based upon determinations made on Merino carcasses in the nutrition laboratory of the Council for Scientific and Industrial Research, Australia.

The tables are prefaced by brief discussions concerning the energy, protein, mineral, and vitamin requirements of man, and the general nutritional contribution of breadstuffs and meats. The food composition tables give data on the percentage of proximate constituents and minerals, and on the calorie and vitamin values per pound of the edible portion (percentage on the as-purchased basis indicated) of all foods. Vitamins A, B<sub>1</sub>, riboflavin, and C, and among the minerals, the calcium, total and available (ionizable) iron, and total and available (non-phytic) phosphorus, are considered.

**Effect of various concentrations of papain and potassium iodate on the loaf volume of bread,** J. DAVIDSON and J. A. LECLEERC (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 3, pp. 145-152, figs. 3).—"The results of baking tests show that there is a consistent interaction between various concentrations of papain and potassium iodate in their effect on the loaf volume of bread. When added singly, some concentrations of potassium iodate and papain depress the loaf volume of bread, the extent of depression being directly related to the concentration. When added together, certain of these concentrations counteract each other. While papain stimulates diastatic activity and potassium iodate depresses it, the action of these substances on the loaf volume of bread cannot be ascribed to their effect on the diastatic power of the flour since sodium chloride, which is always used in bread baking, also stimulates diastatic activity, yet causes no depression in loaf volume."

**The nutritive value of some Tanganyika foods.—II, Cassava,** W. D. RAYMOND, W. JOJO, and Z. NICODEMUS (*East African Agr. Jour.*, 6 (1941), No. 3, pp. 154-159).—Based upon analyses presented, the following figures for the composition of fresh peeled cassava root are suggested for use in dietary calculations: Moisture 62 percent, protein 0.7, fat nil, and carbohydrate 30 percent. Analyses showed the calcium content to vary from 31.26 to 51.35 mg. per 100 gm. of fresh peeled root, phosphorus from 104.6 to 199.5, and iron from 0.18 to 0.37 mg. Determinations of ascorbic acid gave values from 30.9 to 54.6 mg. per 100 gm. for 4 samples of raw peeled root and from 12.3 to 52.4 (average 29.3) mg. for 91 varieties of raw whole roots. The skin was less rich in ascorbic acid than the edible peeled roots; these latter when boiled lost about half of their ascorbic acid, but roasting caused only slight loss. Cyanogenetic glucosides present in appreciable quantities in the raw roots were destroyed upon cooking. The leaves, analyzed without leaf stalk, were very rich in ascorbic acid, containing from 325.6 to 381.4 (average 353.2) mg. per 100 gm. when freshly picked. Storage at tropical room temperatures caused rapid and pronounced losses of ascorbic acid, the leaves containing but 75.1 mg. of ascorbic acid per 100 gm. after 1 day and only 37.5 mg. after 3 days of storage. The carotene content of the leaves varied from 9,746 to 11,136  $\mu$ g. per 100 gm. in the fresh state. Losses of vitamin C and carotene upon cooking (boiling until tender in a small amount of water) were slight, but the cyanogenetic glucoside present in the raw leaves was destroyed upon cooking. Determination of phosphorus, calcium, and iron in the leaf blade gave values of 0.098, 0.187, and 0.003 percent, respectively. Oxalic acid in the leaves was high, averaging 108.9 mg. per 100 gm. Juice extracted from the fresh leaves and concentrated in vacuum gave a preparation that kept well and that contained upwards of 2,000 mg. of ascorbic acid per 100 gm.

**Biological values of soybean protein and mixed soybean-pork and soybean-egg proteins in human subjects,** L. T. CHENG, H. C. LI, and T. H. LAN (*Chin. Jour. Physiol.*, 16 (1941), No. 1, pp. 83-89).—The results of nitrogen balance studies conducted by the Mitchell method (*E. S. R.*, 51, p. 407) on three human subjects are reported. During the test period the three subjects received diets containing 2.6 percent of protein, which supplied about 4 percent of the calories,

as furnished, respectively, by soybean curd, a mixture of 3 parts of pork protein and 7 parts of soybean protein, and a similar mixture of egg and soybean proteins. The digestibilities of these several proteins were found to be 97, 96, and 94 percent, respectively, and the biological values 64, 67, and 77, respectively.

**Biological values of proteins in watermelon and pumpkin seeds**, T. E. KING (*Chin. Jour. Physiol.*, 16 (1941), No. 1, pp. 31-35).—The Mitchell nitrogen balance method (E. S. R., 51, p. 407), applied to the proteins of watermelon and pumpkin seeds at a 10-percent level of intake, gave results indicating digestibilities of about 92 percent and biological values of the proteins of 73 and 63, respectively.

**Poultry cooking**, L. M. ALEXANDER (*U. S. Dept. Agr., Farmers' Bul.* 1888 (1941), pp. II+33, figs. 31).—Cook at moderate heat, and vary the cooking method according to the age and fatness of the bird—these are given as the two rules of modern poultry cooking. The methods, including broiling, frying, roasting, braising, stewing and steaming, and the cooking of smoked turkey, are given, together with a guide to quantities and recipes, including those for stuffings and for favorite chicken combinations, and suggestions for carving.

**Annual review of physiology, III**, edited by J. M. LUCK and V. E. HALL (*Stanford University, Calif.: Amer. Physiol. Soc. and Annual Rev., Inc.*, 1941, vol. 3, pp. VIII+784).—Among the 26 reviews comprising this annual publication (E. S. R., 86, p. 123), the following deal with topics of special nutritional significance: Developmental Physiology, by E. Witschi (pp. 57-78); Growth, by C. E. Palmer and A. Ciocco (pp. 79-106); Energy Metabolism, by T. M. Carpenter (pp. 131-150); The Digestive System, by J. E. Thomas (pp. 233-258); Liver and Bile, by W. B. Hawkins (pp. 259-282); Formed Elements of the Blood, by G. M. Higgins (pp. 283-312); Endocrine Aspects of the Physiology of Reproduction, by O. Riddle (pp. 573-616); and Reproduction in Mammals, by M. H. Friedman (pp. 617-642).

**Anthropometric data on college women of the Middle States**, E. G. DONELSON, M. A. OHLSON, B. KUNERTH, M. B. PATTON, and G. M. KINSMAN. (Minn., Iowa, Kans., Ohio, and Okla. Expt. Stas. and Kans. State Col.). (*Amer. Jour. Phys. Anthropol.*, 27 (1940), No. 3, pp. 319-332).—"Anthropometric measurements of 1,013 college women from the States of Iowa, Kansas, Minnesota, Ohio, and Oklahoma are reported. The measurements taken were [chosen primarily for the purpose of indicating the nutritional status of the individual and included] height, weight, chest breadth (lateral), chest depth (anteroposterior), girth of the arms and left leg, and pressure of the right and left hands. There were 437 Old Americans [persons whose ancestry has been American for at least three generations] observed. Seventy-eight percent of the Oklahoma students were Old Americans, 62 percent of the Ohio group, 45 percent of those from Kansas, 27 percent of the Minnesota group, and 21 percent of the Iowa students. The means for the Old Americans were slightly smaller for all measurements than the means for those not classed as Old Americans, with the exception of the chest breadth and depth which were no different; the girth measurements were significantly smaller. The measurements, ranked according to degree of variability expressed by the coefficient of variation, follow in increasing order of magnitude: Height, chest breadth, chest depth, leg girth, arm girths, weight, and pressure. The measurements for height, weight, girth of right arm, and leg circumference show a small consistent increase with ages 17, 18, and 19 yr. The women measured for this study excel in height and weight previously measured college women from the respective States. The chest diameter measurements, although of a magnitude similar to earlier measurements on college women, were exceeded slightly by Hrdlička's measurements of Old Americans.

The pressure force measurements varied between States, but all exceeded that determination by Hrdlička for adult Old Americans."

**Width-weight tables (revised)**, H. B. PRYOR (*Amer. Jour. Diseases Children*, 61 (1941), No. 2, pp. 300-304, fig. 1).—Revised width-weight tables differ from the earlier ones chiefly in taking into consideration lateral measurements of the chest, as well as biiliac diameters. The method of developing the tables is described, and the resulting tables for 15-year-old girls are presented to illustrate their use.

**Physical measurement of young children**, V. B. KNOTT (*Iowa Univ. Studies Child Welfare*, 18 (1941), No. 3, pp. 99, figs. 15).—In this investigation of the reliability of anthropometric measurements of children of preschool age, 35 physical measurements were obtained on 131 children between 3 and 6 yr. of age. For most of the measurements each child was measured separately by two technicians, and for five of the measurements two observations by the same technician were secured. The data analyzed included 3,643 differences between the independent observations of the two technicians and 221 differences between the two observations by the same technician.

The report includes chapters on the relation of anthropometric reliabilities to the scientific study of physical growth; the literature dealing with the reliability of the measurements; aims, material, and method of analysis; separate chapters dealing with the reliability of measurements of length, transverse and anteroposterior diameters, girths, and skin and subcutaneous tissue; reliability of measurements in relation to their magnitude and rate of growth; and a final chapter presenting a summary and conclusions.

Of special interest are the author's estimates of the approximate frequency of measurement considered profitable during the preschool years. These include stature 10 times a year; hip width, sitting height, leg girth, and total arm length from 3 to 4 times a year; head, chest depth, and elbow width every 2 yr.; and the remaining measurements chiefly once a year.

**The blood sedimentation rate in healthy girls**, L. BENSON and E. J. ROGERS. (*Univ. Vt.*). (*Jour. Lab. and Clin. Med.*, 26 (1941), No. 6, pp. 987-989).—Blood sedimentation rates, determined by the Cutler method, are reported for 327 presumably healthy girls, all of whom were known not to have been ill at any time within 4 mo. after the blood was withdrawn for the original tests. Ninety-two percent of the girls had rates between the limits of 2 and 13 mm. per hour, whereas the rates of 8 percent of the girls ranged from 14 to 25 mm. per hour. The median fell at 7 mm. "This study suggests that in young women the blood sedimentation rate is variable, and that about 10 percent of healthy young women may have sedimentation rates of greater velocity than the average arbitrary range. The diagnostic value, therefore, of the erythrocyte sedimentation rate must be guided by these normal variations."

**Measure of metabolic speed in children**, M. TOBIAS and L. STOCKFORD (*Amer. Jour. Diseases Children*, 61 (1941), No. 4, pp. 675-686).—Data obtained in routine pediatric practice, concerning metabolic rate, total serum cholesterol, and carpal development (bone age), were used in this study. The subjects, selected at random as ones for whom two or more of these measurements had been made, represented clinically constitutionally inadequate children and included 125 boys and 91 girls. These children ranged from 1 to 14 yr. in age. Correlations of the accumulated data were made by the Pearson product-moment method in order to establish the relative validity of each procedure as a measure of metabolic speed. No significant relation was demonstrated between age and sex and the three measures of metabolic speed. The data, analyzed according to the interrelations of the three measures, showed that "the assessment of

delay in carpal development is not a measure of 'slow metabolic speed.' Determination of the level of total cholesterol is a simple and valid measure of a low level of maintenance basal metabolic rate activity in children. Determinations can be satisfactorily accomplished for children beyond the age of 2 yr. When the basal metabolic rate is within the so-called normal limits of  $\pm 10$  and  $-10$  percent, its normalcy must be authenticated by measures of both the total cholesterol and the skeletal development. Determinations of basal metabolic rate are less reliable than are determination of total cholesterol as measures of slow metabolic speed."

**Clinical appraisal of growth in children, J. D. BOYD** (*Jour. Ped.*, 18 (1941), No. 3, pp. 289-299, figs. 5).—The fallacy of attempting to appraise the growth of individual children by comparison with standard height-weight-age tables is discussed, with illustrative growth curves from the author's experience and the literature. Practical recommendations are given as follows:

"In each physical examination of the infant or child, include records of certain specific measurements and data regarding the rate and degree of growth and development. Appraise these against available standards of normality. Do not assume with finality that the child who falls within these standards is developing as well as he may be able to do under improved circumstances. When the infant or child falls below such standards, do not explain away his status without assuring yourself that correctable abnormality of body or of manner of life is not present. Finally, accept standards of growth and development for what they are—cross-sectional averages of children from diverse groups and of varied levels of health—rather than ideals of achievement."

**Nutritional status of school children in a small industrial city, S. L. ZAYAZ, P. B. MACK, P. K. SPRAGUE, and A. W. BAUMAN.** (Pa. State Col. et al.). (*Child Develpmt.*, 11 (1940), No. 1, pp. 1-25, figs. 13).—In this comparison of the dietary habits and nutritional status of 428 school children in an industrial city of about 82,000 population where low incomes prevail, the families were arbitrarily grouped in five income classes from class A of \$5,000 annual cash income and above to class E on direct Government relief, and also in five education level groups from class A with all adults college graduates to class D with no adult a high school graduate. The dietary habits were estimated in terms of weekly intakes of the principal food groups from records kept by some adult in the family of the food consumption of each child during a typical three-meal week day and similar records kept by the child for 2 days. Nutritional status was evaluated from nine tests as described by Mack and Smith (*E. S. R.*, 82, p. 130).

The weekly average intakes of the various types of foods, grouped by income classes, showed a decrease from higher to lower incomes in the consumption of milk, meat, eggs, citrus fruits, and green vegetables; little or no difference between C and D and E combined in yellow vegetables, tomatoes, and bread; and a higher consumption of fruit other than citrus in C than in the other two groups. An association between family income and response to the nutritional tests was evident in physical examination, skeletal status, hemoglobin, and dark adaptation but not for the other factors. The same tendencies were shown in comparisons with the educational status.

**The school lunch as a supplement to the home diet of grade school children, M. E. LOWTHER, P. B. MACK, C. H. LOGAN, A. L. O'BRIEN, J. M. SMITH, and P. K. SPRAGUE.** (Pa. State Col.). (*Child Develpmt.*, 11 (1940), No. 3, pp. 203-247, figs. 5).—In this investigation in which the authors had the cooperation of J. J. Shaw and P. Dodds, the procedures outlined by Mack and Smith (*E. S. R.*, 82, p. 130) were followed in the appraisal of the nutritional status

and dietary habits with relation to socioeconomic status of 225 grade school children chosen from two communities described in the report of Zayaz et al. noted above in such a way as to represent the family cash-income distribution of the school children in the combined communities.

Analysis of the dietary records showed that energy intake tended to fall slightly with descending classes, protein declined gradually, calcium sharply, phosphorus less abruptly than calcium, iron gradually, vitamin A abruptly, vitamin B<sub>1</sub> and riboflavin gradually. The vitamin C intake equaled or exceeded the U. S. D. A. Bureau of Home Economics standards (E. S. R., 81, p. 142) in all groups but C. A similar distribution of nutritional status ratings led to the conclusion that "both the responses to the nutrition tests and the analysis of the dietary intakes of the children clearly indicate the need for improvement in nutritional status of a considerable proportion of the children in all socioeconomic groups, with this need becoming more acute as the socioeconomic level becomes lower."

**The preparation of a casein hydrolysate for the study of the relationship between choline and homocystine.** A. D. WELCH (*Jour. Biol. Chem.*, 137 (1941), No. 1, pp. 173-181, fig. 1).—Hydrolysis of casein with concentrated hydriodic acid, by the method described, resulted in a mixture of amino acids grossly deficient in methionine, homocystine, homocysteine, and tryptophan, as indicated by growth tests with rats fed the casein hydrolysate with and without these amino acid supplements in an otherwise adequate diet. The casein hydrolysate is recommended as a relatively inexpensive substitute for mixtures of purified amino acids for the study of the relationship between choline and homocystine. The need for choline (or betaine) in order to enable the rat to utilize the homocystine for growth, and the ineffectiveness of the arsenic analog of choline chloride in this respect were demonstrated in confirmation of these discoveries by Du Vigneaud et al. (E. S. R., 84, p. 274). The lower homolog of methionine, S-methylcysteine, the  $\beta$ -methyl derivative, and the methyldiethyl homolog of choline chloride were also ineffective in inducing growth on a diet containing homocystine in place of methionine.

**Choline metabolism.**—V, The effect of supplementary choline, methionine and cystine and of casein, lactalbumin, fibrin, edestin, and gelatin in hemorrhagic degeneration in young rats, W. H. GRIFFITH (*Jour. Nutr.*, 21 (1941), No. 3, pp. 291-306, figs. 3).—In continuation of the series (E. S. R., 86, p. 275), the occurrence and severity of hemorrhagic degeneration in rats fed 25 diets differing in protein content from 18 to 40 percent, in total methionine from 0.4 to 1.2 percent, and in total cystine from 0.05 to 1.2 percent were determined, using as the proteins casein, lactalbumin, fibrin, edestin, and gelatin. As further indices of the degree of choline deficiency, increases in the weight of the kidneys and in the extent of deposition of fat in the liver were determined.

Renal damage was found not to be proportional to the cystine content of the diet in the amounts fed (0, 0.3, 0.5, and 1 percent), and the minimum daily requirement for choline was the same at these various levels. However, the higher cystine levels had a slightly more toxic effect in the absence of added choline. Casein was the most protective of the proteins used, and lactalbumin, fibrin, edestin, and gelatin aggravated the effects of choline deficiency, presumably because these proteins contained less methionine and more cystine. Hemorrhagic degeneration was absent or nearly so in each group receiving more than 8 mg. of methionine per gram of food. Under these conditions choline did not appear to be essential. With lesser amounts of methionine the renal lesions and fat deposits varied according to the methionine and

cystine levels. The choline requirement varied inversely with the dietary methionine and directly with the dietary cystine.

In discussing the significance of these findings, the author points out that "the prevention of hemorrhagic degeneration in young rats is a relatively sensitive test for those metabolites which may supply methyl groups for the synthesis of choline."

**Coccarboxylase, pyruvic acid, and bisulfite-binding substances in children,** H. WORTIS, R. S. GOODHART, and E. BUEIDING (*Amer. Jour. Diseases Children*, 61 (1941), No. 2, pp. 226-230).—The subjects of this study were children hospitalized because of conduct disorders, behavior problems, psychoneuroses, and mental deficiency, but showing none of the recognized signs of vitamin B<sub>1</sub> deficiency or conditions which might be expected to produce a vitamin B<sub>1</sub> deficiency.

Blood coccarboxylase values for 50 children from 4 to 15 yr. of age ranged from 4  $\mu$ g. (2 subjects) to 13  $\mu$ g. (1 subject), with an average of  $7.5 \pm 1.82$   $\mu$ g. per 100 cc. For the 24 children who were 12 yr. of age or over the average was  $6.5 \pm 1.38$ , and for the 26 under 12 yr. of age  $8 \pm 2.06$   $\mu$ g. per 100 cc., as compared with an average of  $7.0 \pm 2.1$   $\mu$ g. per 100 cc. reported by Goodhart and Sinclair (*E. S. R.*, 83, p. 420) for a group of adult subjects. A trend toward higher values in young children is suggested. Blood pyruvic acid values for 35 children between 7 and 16 yr. of age ranged from 0.71 to 1.21, with an average of 0.96 mg. per 100 cc., and for 60 adults from 17 to 70 yr. of age from 0.77 to 1.16, with an average of 0.98 mg. Values for the cerebrospinal fluid for both children and adults were in practically the same range. Bisulfite-binding substances in the blood of 93 children from 3 to 16 yr. of age ranged from 2.0 to 4.9, with an average of 3.55, and in cerebrospinal fluid from 0.42 to 1.79, with an average of 1.24 mg. per 100 cc. Corresponding values for 105 adults from 17 to 70 yr. of age were blood from 2.00 to 5.72, with an average of 3.84, and cerebrospinal fluid from 0.42 to 3.07, with an average of 1.63 mg. per 100 cc., respectively. It is reiterated (*E. S. R.*, 84, p. 705) that the value of bisulfite-binding substances in blood and cerebrospinal fluid cannot be used as an indication of vitamin B<sub>1</sub> deficiency or as an accurate measure of the levels of pyruvic acid in these fluids.

**Coccarboxylase content of blood of infants and of children,** F. W. SCHLUTZ and E. M. KNOTT (*Amer. Jour. Diseases Children*, 61 (1941), No. 2, pp. 231-236).—A series of blood coccarboxylase values determined by the method of Goodhart and Sinclair (*E. S. R.*, 83, p. 420), with a few modifications, is reported for healthy and ill infants and children, and a few women in labor and during lactation, with in some instances values for the same subjects following thiamin therapy.

Well-nourished subjects in general had values of 10  $\mu$ g. or above per 100 cc. and chronically and acutely ill subjects lower values. Thus, an apparently healthy breast-fed infant 10 weeks of age gave a value of only 7.0  $\mu$ g. per 100 cc., which increased to 14.7  $\mu$ g. after the mother's diet had been supplemented with 500 International Units of thiamin chloride daily. Two healthy infants of the same age, hospitalized for metabolism studies and receiving the same type but not the same quantities of food (breast milk and evaporated milk formulas), were tested at frequent intervals from 7 to 20 weeks of age. The larger of the two maintained a fairly constant coccarboxylase level of about 12  $\mu$ g. per 100 cc., while the values for the other gradually decreased from 10.8 to 8  $\mu$ g. per 100 cc. At a level of 9.2  $\mu$ g. symptoms of slight vitamin B<sub>1</sub> deficiency were evident. Final coccarboxylase levels of 13.1 and 10.1  $\mu$ g. per 100 cc., respectively, were obtained following the fortification of the milk formula with vitamin B<sub>1</sub>, 133 I. U. of thiamin chloride being used daily in the second case. Three women in labor had values

of 8.7, 8.9, and 8.6  $\mu\text{g.}$  per 100 cc.; during lactation on a regular diet 4.9, 10.3, and 13.8  $\mu\text{g.}$ ; and on a regular diet supplemented with 500 I. U. of thiamin chloride daily 11.3, 11.1, and 23.0  $\mu\text{g.}$  per 100 cc. daily.

In the opinion of the authors cocarboxylase determinations give a reliable estimate of the thiamin content of vital fluids, especially the blood, and should be of aid in detecting subclinical vitamin B<sub>1</sub> deficiency.

**The formation of pyruvic acid following ingestion in man,** E. BUEDING, M. H. STEIN, and H. WORTIS (*Jour. Biol. Chem.*, 137 (1941), No. 2, pp. 793-794).—In 21 experiments on 17 healthy, well-nourished subjects, glucose and pyruvic acid were determined in the blood under basal conditions, following which glucose at the level of 1.75 gm. per kilogram of body weight was ingested in 25 percent solution. Blood pyruvic acid was determined by the method of Bueding and Wortis (*E. S. R.*, 85, p. 852) at 30- to 60-min. intervals over a period of from 4 to 6 hr. The maximum rise usually occurred at the end of 1 hr. (30 min. in one case) and ranged from 0.14 to 0.93 mg., averaging 0.43 mg. per 100 cc. Following the peak, the level fell to normal at or before the third hour in all but one case. "These observations indicate either (1) that pyruvic acid is a normal intermediary in the metabolism of glucose in man, or (2) that the ingestion of glucose by mouth stimulates the formation of pyruvic acid in some other way."

**The absorption and fate of free citric acid in the rat,** C. A. KUETHEB and A. H. SMITH (*Jour. Biol. Chem.*, 137 (1941), No. 2, pp. 647-658).—Citric acid at the level of 100 mg. per 100 gm. of body weight was administered in 10 percent solution by stomach tube to fasting rats. The amount remaining in the gut after  $\frac{1}{2}$ , 1, 2, 3, and 5 hr. was determined in animals sacrificed at these intervals. The amount of citric acid absorbed was calculated as the difference between the amount administered and that recovered minus the amount present in the fasting gut, as determined in a separate control group. Other experiments showed that the stomach and small intestines and their contents upon ligation and removal from the rat did not destroy the citric acid then injected into the stomach, when the whole was incubated in Tyrode's solution for 5 hr. This evidence indicated that the orally administered citric acid was probably not destroyed by bacteria or enzymes present, and that the amount that disappeared from the gut was truly absorbed.

Data on the absorption of citric acid showed that under the conditions of the experiment about 90 percent was absorbed within 5 hr., with the rate of absorption greatest for the short intervals and decreasing as the period was lengthened. This suggested that the rate of absorption was proportional to the amount of material in the gut. Glycogen, determined in all livers following the administration of citric acid to the rats, increased from the  $\frac{1}{2}$ -hr. period, with a peak at 3 hr., after which the concentration decreased. The rise and subsequent fall were interpreted as probably indicative of two opposing tendencies, synthesis and hydrolysis of glycogen. During the earlier periods the rate of synthesis was the greater, resulting in an increase in glycogen, but in the later periods, with decrease in rate of synthesis as the absorption rate decreased and with continuing hydrolysis, the net result was a decrease in liver glycogen. The quantitative data for citric acid absorbed and glycogen formed suggested a mole for mole relationship.

**The calcium content of the normal growing body at a given age,** K. E. BRUWA and H. C. SHEEMAN (*Jour. Nutr.*, 21 (1941), No. 2, pp. 155-162).—To find whether it is age or the individual rate of growth which determines the percentage of calcium in the normal animal, the percentage of body calcium was determined in over 400 rats from a long-established stock colony, selected for analysis at the age of 28 days or the "end of infancy." Animals were taken from families on

three dietaries based on two-thirds ground whole wheat and one-third dried whole milk, but differing in calcium supplements so that dietary calcium was 0.35, 0.49, and 0.64 percent in the three diets, respectively. The results of the analyses of the animals of the six series (each sex from each of the three family diets) were studied statistically for possible influence of body size at the given age.

In none of the six comparisons did the heavier animals show a significantly higher percentage of body calcium than the lighter animals, as would be the case if higher body weight meant greater maturity of skeletal development at the age studied. Comparisons of animals grouped as large, medium, and small showed slightly higher percentages of calcium in the small and slightly lower percentages in the large animals than in those of medium size representing the average for their age, sex, and nutritional background. These differences were so small, however, that none were statistically significant. It is concluded, therefore, that "among normal growing individuals of a given sex, having the same hereditary and nutritional background, age is the predominant determining factor in the increasing percentage of calcium in the body."

**Influence of different nutritional conditions upon the level of attainment in the normal increase of calcium in the growing body,** C. S. LANFORD, H. L. CAMPBELL, and H. C. SHERMAN (*Jour. Biol. Chem.*, 137 (1941), No. 2, pp. 627-634).—Purebred albino rats from a long established colony received the basic diet composed of one-third whole milk powder, two-thirds ground whole wheat, and salt to the extent of 2 percent of the wheat. This diet, containing from 0.34 to 0.35 percent of calcium, was better balanced and of higher protein and initial calcium content than the diet previously used in a similar study (*E. S. R.*, 81, p. 451). One group received only the basal diet, while the others received this diet supplemented with calcium carbonate to bring the calcium levels to 0.48 and 0.64 percent, respectively. Animals at 28, 60, 90, and 180 days and 1 yr. of age were selected for analysis from second and third generations of each of these three dietary families. Net body weight (gross body weight less weight of the gastrointestinal contents) and the weight and percentage of body calcium are reported for males and females separately as averages for animals in each age group in each dietary family. The data, analyzed for statistical significance, showed that increasing the calcium content of this superior diet resulted in successive increases in percentage of body calcium at a given age, the difference induced by each stepwise increment being one-tenth to one-twelfth at the period of most rapid growth and about one-thirtieth at full maturity. Rats on the highest level of calcium intake attained at the age of 2 mo. a percentage of body calcium (0.80 percent) which those on the diet with 0.35 percent calcium required 50 days more to attain. At 28 days of age only a low degree of association existed between degree of calcification and body size, this finding being in agreement with that of Briwa and Sherman as noted above. For later ages, however, the data indicated that greater than average body weight tended to be accompanied by lower than average percentage of body calcium and vice versa. This interrelationship appeared to be at least as marked at the more liberal as at the lower levels of calcium intake and at least as marked at full maturity as during rapid growth.

**The changes in composition of solutions of calcium chloride and calcium lactate in the intestine,** C. S. ROBINSON, D. E. STEWART, and F. LUCKEY (*Jour. Biol. Chem.*, 137 (1941), No. 1, pp. 283-292, fig. 1).—The present study, representing an extension of earlier work (*E. S. R.*, 73, p. 718) dealing with the regulation and changes in intestinal reaction, is concerned with detailed experimental analysis of changes in water content and in H-ion, cation, and anion concen-

trations in perfused intestinal loops of dogs with Thiry-Vella fistulas. The experiments, which are described, involved the establishment of the fistula and, after healing of the ends, circulation of solutions of calcium chloride and calcium lactate of known composition for 3 hr. without change in pressure. At the end of the period the solutions were analyzed. The changes in composition indicated that concentrated acid solutions of calcium chloride yielded the most calcium to the body, but that acidity did not increase absorption of calcium from lactate solutions, although increase in concentration did increase the amount absorbed. Hence, the particular salt involved, as well as the concentration and acidity of the solution, were of importance in determining the amount of calcium absorbed. Alkaline solutions quickly became acid, partly by an influx of  $\text{CO}_2$ . Water and salts passed in either direction through the intestinal wall to alter the osmotic pressure of the intestinal contents. The acidosis of calcium chloride was apparently not caused by selective absorption of chloride ion from the intestine, but by displacement of other cations by calcium whose subsequent excretion caused a deficit in total cations.

**Red cell volume circulating and total as determined by radio iron, P. F. HAHN, W. M. BALFOUR, J. F. ROSS, W. F. BALE, and G. H. WHIPPLE** (*Science*, 93 (1941), No. 2404, pp. 87-88).—Radioactive iron given by mouth or vein to anemic dogs was found to be rapidly used up in the construction of new hemoglobin within newly formed red cells (*E. S. R.*, 85, p. 418). In the study here reported red cells containing the radio iron were given by vein to eight dogs, six of which were normal, and the degree of dilution noted after varying periods allowed for mixing of the ordinary and labeled red cells. The true circulating red cell volume determined by this method averaged about 75 percent of the value as computed from the jugular hematocrit and the plasma volume (dye method), indicating an inherent error of about 25 percent in this latter method. The red cell volume measured by dilution of the injected labeled red cells was almost the same after 10 min. as after from 1 to 3 days, average differences between the two values amounting to only 3 percent. This indicated that in these normal dogs the number of immobilized red cells in marrow, spleen, and other vascular spaces did not exceed 10 percent of the circulating mass and may have been considerably less. It is suggested that this method can be used to study human physiology, normal and abnormal.

**Sensitivity of the dark-adapted eye during a prolonged period of observation, B. SEMEONOFF** (*Nature [London]*, 147 (1941), No. 3728, pp. 454-455, fig. 1).—In this study, undertaken to determine if the course of dark adaptation is affected by fatigue, a single subject trained in adaptation tests underwent two tests during periods of 6 hr. from 10 or 10:30 p. m. to 4 or 4:30 a. m. after an ordinary day's activity followed by 3 hours' fire-watching duties. In the first test adaptation was carried out in complete darkness and in the second in diffuse red light bright enough to read by with difficulty. The Nagel adaptometer was used, and readings were taken following 10 min. of preliminary light adaptation, and then at intervals of 5 min. during the entire 6 hr. No significant differences were found in the readings with prolongation of time in either test. This indicates that at least for the trained subject ordinary fatigue at the end of a normal day's sedentary work has no effect on the adaptation process as a measure of the maximum level attained, and suggests that it is possible to maintain accurate observations in the dark-adapted state during a protracted period of enforced wakefulness.

**A survey of nutrition and dental caries in 120 London elementary school children, I. ALLEN** (*Brit. Med. Jour.*, No. 4175, (1941), pp. 44-46).—In an examination over a period of 1 yr. of 120 elementary school children for dental caries

and surface structural defects of the teeth, together with height-weight determinations as an index of nutritional status, "(1) the lower incisors and canines showed the best surface structure and the molars the worst, the upper incisors and canines being intermediate; the structurally soundest teeth are, therefore, those of which the greatest part is formed in utero before dietary deficiencies are normally felt by the child. (2) A definite association existed between the quality of the structure of the teeth and the amount of caries present. The better the structure the greater the resistance to dental disease. (3) An improvement in physical condition as judged by an increase in the nutrition (weight/height) index at ages 5 and 6 was found to be fairly strongly associated with a smaller increase in dental caries."

**Studies on the relationship between diastatic activity of saliva and incidence of dental caries**, H. J. FLORESTANO, J. E. FABER, and L. H. JAMES. (Univ. Md.). (*Jour. Amer. Dent. Assoc.*, 28 (1941), No. 11, pp. 1799-1803, fig. 1).—Ptyalin was determined by the starch-iodine technic in saliva from 166 subjects classified according to their dental condition into three noncarious groups and five carious groups showing progressive caries development. In general the time required for starch hydrolysis was greater in the noncarious cases, the time for complete diastatic action of the saliva averaging 9.3 min. for the 76 noncarious cases and 4.0 min. for the 90 carious cases. For each group the average diastatic action showed a direct relation to the incidence of caries, the greater diastatic activity being accompanied by a higher incidence of tooth decay. It is suggested that the diastatic activity of saliva be used as an index of caries susceptibility.

**Cure of signs of egg white disease by corn oil fatty acids and vitamin B<sub>6</sub>**, E. M. MACKAY and R. H. BARNES (*Soc. Expt. Biol. and Med. Proc.*, 46 (1941), No. 2, pp. 353-357, fig. 1).—Egg white injury in rats resulting from including commercial dried egg white in the ration in considerable amounts developed much more slowly when 10 percent of the fat in the diet was in the form of corn oil than as hydrogenated cottonseed oil. The injection of vitamin B<sub>6</sub> into corn oil-fed rats also brought about the almost complete disappearance of signs and symptoms of egg white injury.

**Vitamin-Tabellen der gebräuchlichsten Nahrungsmittel** [Vitamin tables of the most common foods], W. DROESE and H. BRÄMSEL (*Ernährung, Beiheft* 8 (1941), pp. [4]+63).—These tables, set up separately for each vitamin, give average values, expressed in milligrams or gamma per 100 gm., for the content of vitamins A, B<sub>1</sub>, B<sub>2</sub> (lactoflavin), P-P factor (nicotinic acid), C (ascorbic acid), and D in foodstuffs most commonly in use in Germany, these being classified as meat; game; fish; milk and cheese; butter and fat; cereals; legumes; root, stem, leafy, and fruit-form vegetables; fruits and fruit juices, etc. The averages are based on selected values from studies (chosen from literature available) considered satisfactory from the standpoint of methodology and statistical accuracy of the data. Supplemental tables indicate the bibliographic references giving the data upon which each figure is based. The bibliography includes 510 references. For the most part figures are given only for fresh and raw material, but where available values are also reported for cooked, canned, dried, frozen, or preserved products. Preceding each table, brief notations are given concerning the nature and chemical properties of the vitamin in question, the clinical picture in case of its deficiency, general nature of the methods of determination, factors employed for converting various units to milligrams or gamma, and a statement concerning the daily requirements.

**Vitamin A contents of Shanghai foods.—II, The colorimetric assay of 25 common fishes**, P. G. MAE (*Chin. Jour. Physiol.*, 16 (1941), No. 1, pp. 67-72).—

Vitamin A values determined by the method of Moore (E. S. R., 81, p. 451) and expressed as blue units per 100 gm. of fresh flesh are reported for 25 fishes designated by common and scientific names. Data on percentage of edible portion are also reported.

**Carotene and human requirements, A. L. BACHARACH** (*Chem. and Indus.*, 60 (1941), No. 23, pp. 435-436).—Calling attention to the shortage of preformed vitamin A in England and the increasing necessity for the adult population to rely upon the carotenoids as the chief source of this vitamin, the author emphasizes the unlike effectiveness of different carotenoids as vitamin A precursors and the variation from species to species and from individual to individual in the power of converting the carotenoids into vitamin A, and states that the utmost caution "must be used in calculating the vitamin A contents of human dietaries when the vitamin A is not preformed but is derived from the carotenoids of plant foods." Among the sources of error in such calculations are (1) the calculation of inactive or partially active carotenoids as if they were  $\beta$ -carotene, particularly likely to happen if colorimetric or to a lesser extent spectrophotometric methods are used for estimating the total carotenoids unless chromatographic or other separation has been carried out; (2) possible failure of absorption of carotenoids of different foods, knowledge of this point being incomplete; (3) incomplete absorption through the influence of other factors such as mineral oil; (4) uncertainty as to the effectiveness of conversion of carotenoids into vitamin A, nothing being known about the biochemistry of this process; (5) variations in the effective utilization of carotene with the deficiency of the subject, an inverse relationship being apparent; and (6) possible losses in cooking, although these are generally slight.

"For the reasons enumerated above, carotene is a less effective source of vitamin A activity for the human being; and may be a very much less effective source than the preformed vitamin. In calculating food values from tables of nutrient analyses, including vitamin contents, it is considered advisable to equate not less than 2  $\mu$ g. of  $\beta$ -carotene to 1 International Unit of vitamin A. Where an appreciable proportion of the provitamin consists of compounds containing only 1  $\beta$ -ionine ring, a corresponding further increase must be made in the amount of carotene taken as equivalent to 1 I. U."

**Calcium in the alimentary tract of the rat, W. H. ADOLPH and C. O. LEANE** (*Jour. Biol. Chem.*, 137 (1941), No. 2, pp. 517-523).—The technic used for studying calcium absorption with rats utilized not fasting animals but those taken from the stock diet and placed for a 4-day period on a diet practically free of calcium but liberal in roughage and adequate in other respects. The rats were then given by stomach tube 2 cc. of calcium lactate containing 10.4 mg. of calcium, after which they were killed at 1-, 2-, and 3-hr. intervals. The alimentary tracts were ligated and removed, and the contents of the stomach, small intestine, cecum, and large intestine were analyzed for calcium. A control group receiving only water was similarly treated. The total amount of calcium found in the alimentary tract of this control group averaged 0.87 mg. per 100 gm. of body weight. This, presumably representing the small amount of calcium contained in the digestive juices plus unabsorbed calcium from the basal diet, was regarded as a blank and was subtracted, in calculation of the amount absorbed by the experimental animals, from the calcium found in the intestinal tract per 100 gm. of body weight. The absorption coefficient, calculated as milligrams of calcium absorbed per hour per 100 gm. of rat body weight, averaged 3.6, 2.2, and 1.5 after absorption periods of 1, 2, and 3 hr.

When the same amount of calcium (as calcium borogluconate solution) was injected intravenously instead of being administered by stomach tube, there was

no significant change in the amount of calcium found in the intestinal tract after the several intervals, even when the body tissues of the animals were saturated with calcium by daily subcutaneous injection of 9.2 mg. of calcium (as borogluconate) during the 4-day period. The subsequent intravenous injection of calcium at 14.3- and 28.6-mg. levels did not produce any significant increase in the amount of calcium in the intestinal contents. These results indicate that in the rat the intestinal tract does not excrete calcium in amounts which are related to the metabolic calcium level.

**Severe calcium deficiency in growing rats, I-III.** (Univ. Calif. et al.). (*Jour. Nutr.*, 21 (1941), No. 1, pp. 61-74, figs. 3; pp. 75-84, figs. 4; 22 (1941), No. 1, pp. 1-6, fig. 1).—Three papers are presented.

I. *Symptoms and pathology*, by M. D. D. Boelter and D. M. Greenberg.—This study is concerned with the symptoms and pathological changes induced in rats kept for long periods on diets low in calcium. These diets, similar to those used by Tufts and Greenberg (*E. S. R.*, 80, p. 275), usually contained but 10 mg. of calcium per 100 gm. of food, although in some cases they contained 4 or 20 mg. The basal diet, containing 546 mg. of calcium per 100 gm., and the control and low-calcium salt mixtures were the same as those used by Kleiber et al. (*E. S. R.*, 85, p. 417).

Rats reared on the low-calcium diets showed retardation of growth, the divergence from the controls becoming pronounced at the end of the second or third week for those animals receiving the diet containing 10 mg. of calcium per 100 gm. The time required for retardation of the growth rate varied with the calcium content of the diet, taking longest with one containing 20 mg. of calcium per 100 gm. of food. Reduced food consumption, due to decreased appetite, and high metabolic rate both contributed to the decreased growth rate of the calcium-deficient rats. These animals, as compared with normal ones, showed reduced sensitivity and reactivity. They had an abnormal posture and gait and showed susceptibility to internal hemorrhage, which resulted in prostration, paralysis of the hindquarters (frequently fatal), encrusted nostrils, bleeding from the anus, and black, diarrheal feces. The hemorrhages and their consequences of prostration and paralysis were easily induced by mild galvanic shock. There was a large increase in the volume of urine and a reduced span of life.

Autopsy revealed osteoporosis or low-calcium rickets. Rats suffering from the effects of calcium deprivation became normal in all respects a few weeks after they were supplied food with an adequate amount of calcium. The injection of calcium salts usually caused the death of the calcium-deprived animals within a few hours. It is pointed out that muscular weakness and collapse rather than tetany result from severe deficiency of calcium in the diet of the rat, and that the outstanding effect of this regimen is the susceptibility of the animal to hemorrhages.

II. *Changes in chemical composition*, by M. D. D. Boelter and D. M. Greenberg.—This report is concerned with the chemical changes in blood, tissues, and bone accompanying the symptoms and pathological changes observed in the calcium-deficient rats. The data reported for the experimental and control groups indicate that "severe calcium deprivation causes a rapid reduction in the serum calcium concentration and a decrease in the calcium and magnesium content of the whole rat carcass. The serum inorganic phosphorus, magnesium, and phosphatase, red corpuscle magnesium, and the blood sugar do not deviate from normal. There is the usual content of hemoglobin in the blood. The soft tissues maintain their normal mineral content. The bones of the deficient animals are greatly demineralized. The percent of ash and calcium of the bone is only about one-

half the normal. There is a lesser decrease in the phosphorus and magnesium percentage. In the bone ash, the contents of calcium, magnesium, and phosphorus are slightly low, high, and normal, respectively."

III. *Serum calcium of individual animals during development of calcium deficiency*, by D. M. Greenberg and W. D. Miller.—Rats taken from the stock diet when they weighed about 100 gm. were placed on the severely calcium-deficient diet used in the above studies, and the change in serum calcium concentration was followed in each animal during the whole course of the deficiency. Calcium, precipitated as the oxalate from a single drop of blood, was determined by using the cerate-Mohr salt titration procedure with o-phenanthroline as indicator. The serum calcium concentration began to drop almost at once after the animals were placed on the deficient diet, falling to 7.4 mg. per 100 cc. (average eight animals) after 30 days and to 6.1 mg. after 68 days, with little fall thereafter. The serum protein concentration was not altered by the calcium deprivation. Animals subjected to galvanic shock after 9 weeks on the diet showed paralysis and symptoms of hemorrhage but no change in serum calcium concentration. Great depletion of body calcium and phosphorus stores occurred during the depletion period, analyses of five animals yielding values of  $0.426 \pm 0.06$  percent for calcium and  $0.383 \pm 0.03$  percent for phosphorus as against the normal values of 1.0 and 0.75 percent, respectively.

**Ferrous and ferric iron in liver extract**, R. S. FISHER and W. A. PEABODY (*Soc. Expt. Biol. and Med. Proc.*, 46 (1941), No. 2, pp. 207-209).—Simple aqueous extracts of pork liver were found to prevent the oxidation of added ferrous iron and to reduce added ferric iron. The data presented show that from 50 to 95 percent of the added ferric iron was present in the ferrous state at periods from 1 mo. to  $4\frac{1}{2}$  yr. after the addition of the ferric ammonium citrate. It is suggested that "the efficacy of liver and iron combinations in the treatment of the iron-deficiency anemias may be partly due to this action of the liver extract in supplying or maintaining iron in the more easily absorbable ferrous state."

**The response to intravenously injected dextrose in rats on normal and B<sub>1</sub> deficient diets**, D. J. PACHEMAN (*Amer. Jour. Physiol.*, 133 (1941), No. 1, pp. 43-46).—The decrease in tolerance of vitamin B<sub>1</sub>-deficient rats to glucose administered orally, as demonstrated by Lepkovsky et al. (*E. S. R.*, 64, p. 294), is shown not to be due to changes in absorption from the intestines as a similar decrease in tolerance to dextrose administered intravenously has been demonstrated. The tail veins were used for the injection. The progressive decrease in tolerance to dextrose as thus administered was apparently independent of food intake. In similar experiments on rats which had been on a normal diet the response to dextrose administered intravenously was fairly constant.

**Some effects produced by long-continued subminimal intakes of vitamin B<sub>1</sub>**, H. R. STREET, H. M. ZIMMERMAN, G. R. COWGILL, H. E. HOFF, and J. C. FOX, JR. (*Yale Jour. Biol. and Med.*, 13 (1941), No. 3, pp. 293-308, pl. 1).—Contradictory findings in the literature on studies of the nervous system of rats, dogs, and chicks on diets lacking in vitamin B<sub>1</sub> are noted, and experiments are reported in which extensive peripheral nerve destruction was found in dogs maintained for from 200 to 393 days in a state of chronic vitamin B<sub>1</sub> deficiency produced by limiting the B<sub>1</sub> intake to about 2 µg. per kilogram of body weight.

The dogs developed progressively a condition characterized by moderate spasticity of the hind legs, unsteadiness, staggering, and vomiting, while controls restricted to the same food intake but given approximately 8 µg. of crystalline B<sub>1</sub> per kilogram of body weight daily remained in good health throughout the period. "Histological studies of the nervous system of representative animals revealed extensive myelin degeneration of both peripheral nerves and

posterior columns of the spinal cord in two of the animals with chronic vitamin B<sub>1</sub> deficiency, and less extensive degeneration in another. Sections from the control animals disclosed, at the most, only moderate degeneration of peripheral nerves."

**The urinary excretion of thiamin in normal children, R. A. BENSON, C. M. WITZBERGER, and L. B. SLOBODY** (*Jour. Ped.*, 18 (1941), No. 5, pp. 617-620).—A group of 22 normal children, 20 girls and 2 boys, from 4 to 10 yr. of age served as subjects in this study of at least a month's duration of the daily intakes and urinary outputs of thiamin. Intakes were calculated from daily food consumption records by the use of the tables of Williams and Spies (*E. S. R.*, 80, p. 710) and 24-hr. excretions determined by essentially the Hennessy and Cerecedo modification (*E. S. R.*, 82, p. 588) of the thiochrome procedure.

The daily vitamin B<sub>1</sub> intakes averaged 990  $\mu$ g. (330 International Units), with a ration of 45  $\mu$ g. per 100 calories. The outputs ranged from 92 to 602  $\mu$ g., with an average of 268  $\mu$ g., or 27.2 percent of the amount ingested. It is noted that this average is in good agreement with values reported by Light et al. (*E. S. R.*, 82, p. 425) for rats in excretion equilibrium. The ratio did not hold following the injection of a test dose of 5 mg. of thiamin, which resulted in a wide range in excretion values of from 3.3 to 18.3 percent of the intake. No constant relationship was found between the thiamin content of the first sample voided in the morning and the following 24-hr. excretion, showing that it is impossible to predict a 24-hr. output from the morning sample.

Since the children were normal as far as could be judged by history, physical and laboratory examination, and progressive weight gains during the month of the study and the preceding month, their average intake as noted, 45  $\mu$ g., is thought to be adequate to provide for excellent health in children of this age and weight.

**The urinary pyruvate in thiamine deficiency, H. A. HARPER and H. J. DEUEL, JR.** (*Jour. Biol. Chem.*, 137 (1941), No. 1, pp. 233-238).—On the theory that an increase in pyruvic acid in the urine would be a more specific indication of thiamin deficiency than an increase in bisulfite-binding substances, as reported by Banerji and Harris (*E. S. R.*, 83, p. 851) and confirmed by Shils et al. (*E. S. R.*, 84, p. 706), rats on a thiamin-free diet were tested at weekly intervals for urinary pyruvate, as determined by the hydrazine procedure of Lu (*E. S. R.*, 82, p. 587), with simultaneous determinations of 24-hr. urinary creatinine as an index of adequate excretion.

As depletion progressed there was a definite increase in pyruvate excretion. Values for 10 male rats increased from a mean of  $1.84 \pm 0.05$  mg. per day on the sixth day of depletion to  $3.57 \pm 0.34$  mg. per day at the forty-third day and for females from  $1.50 \pm 0.11$  mg. per day at 3 days to  $2.90 \pm 0.21$  mg. per day at the forty-fifth day. With lessened food intake the excretion of pyruvate decreased, although the relation was not strictly quantitative. Thiamin feeding, even in small doses, produced a temporary lowering of pyruvate excretion and suspension of the supplement a return to high levels, but supplements adequate for mineral growth did not suffice to lower the pyruvate levels to the original values. A consistent sex difference in pyruvate excretion was noted, the males giving higher urinary pyruvate values than the females studied under identical conditions of thiamin depletion.

**Nicotinic acid in blood, B. D. KOCHHAR** (*Indian Jour. Med. Res.*, 29 (1941), No. 1, pp. 133-136).—Data obtained by a method similar to that of Swaminathan (*E. S. R.*, 80, p. 131) are reported on the distribution of nicotinic acid in the whole blood, erythrocytes, leucocytes, plasma, and serum of dogs; in the blood of a number of human subjects suffering from various diseases, including lobar

pneumonia, bronchopneumonia, severe anemia, and anemia with diarrhea; and in the blood of a pellagrin with marked anemia.

By far the highest content of nicotinic acid in dogs' blood was in the erythrocyte layer, the values ranging in the four dogs studied from 1,196 to 1,980  $\mu\text{g}$ . percent, and the lowest values in the plasma, from traces to 115, and in the serum from 28 to 120  $\mu\text{g}$ . percent. In the human subjects the values ranged from 252 to 680  $\mu\text{g}$ . percent for the nonpellagrins and from 300 to 412  $\mu\text{g}$ . percent for the pellagrin.

From the similarity in values obtained, it is concluded that the estimation of the nicotinic acid content of blood is probably of little value in the diagnosis of pellagra.

**The inhibiting effect of urea on the microbiological assay of riboflavin,** H. ISBELL, J. G. WOOLEY, and H. F. FRASER (*Pub. Health Rpts. [U. S.]*, 56 (1941), No. 7, pp. 282-285).—Data are presented to show the inhibitory effect of urine on the microbiological assay of riboflavin in urines low in this vitamin. These results confirm the findings of Fraser et al. (*E. S. R.*, 84, p. 564) who, applying the method of Snell and Strong, found that the addition of increasing amounts of such urines to the assay tubes gave progressive diminution of the riboflavin value per cubic centimeter. Further tests, applying this method of assay to solutions of riboflavin containing various individual constituents of urine in physiologic concentrations and above, indicated that urea was the inhibiting substance.

From data on the assay values for riboflavin solutions of various concentrations in the presence of varying amounts of urea, a partial regression equation was established from which the amount of riboflavin actually present could be calculated. Samples of urine, analyzed for urea content and containing known added amounts of riboflavin, were assayed for the vitamin, the values were corrected by the regression equation, and the percentage recovery of added riboflavin was calculated. The tabulated results indicate an average recovery of 103 percent (range 87-118 percent), and suggest that the regression equation may be used to obtain the true amount of riboflavin present in a urine exhibiting the depressing phenomenon.

**Riboflavin contents of some typical fruits,** C. S. LANFORD, B. FINKELSTEIN, and H. C. SHEEMAN (*Jour. Nutr.*, 21 (1941), No. 2, pp. 175-177).—Determination of the riboflavin content of a number of fruits by the feeding method of Bourquin and Sherman (*E. S. R.*, 66, p. 410) gave the following mean values, expressed as micrograms per 100 gm. of the edible portion (described): Apple,  $4.3 \pm 1.2$ ; banana,  $47.7 \pm 4.6$ ; grapefruit,  $20.0 \pm 2.1$ ; grapefruit juice (canned),  $11.8 \pm 1.4$ ; orange,  $27.8 \pm 2.0$ ; pear,  $19.8 \pm 2.8$ ; and tomato,  $37.3 \pm 3.3$ .

**Relation of ascorbic acid concentration in juice of Florida grapefruit to variety, rootstock, and position of fruit on the tree,** P. L. HARDING and E. E. THOMAS. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 1, pp. 57-61).—An earlier study dealt with seasonal changes in the ascorbic acid content of orange juice and the difference in concentration between fruit exposed to the sun and shaded fruit (*E. S. R.*, 83, p. 137). The present study of grapefruit juice is summarized as follows:

The ascorbic acid concentration was determined for 390 individual grapefruits from outside and inside branches of 5 trees each of Marsh grapefruit grown on rough lemon, of Marsh grapefruit grown on sour orange, and of Foster (pink) grapefruit grown on sour orange rootstocks. Fruits from the outside branches from the three sources had a consistently higher ascorbic acid concentration. This difference was found to be significant at the 1-percent level. No significant difference in ascorbic acid content was found between Marsh grapefruit grown

on rough lemon and sour orange rootstocks, although that on rough lemon was slightly higher. A significantly higher ( $P=0.01$ ) ascorbic acid concentration was found in Foster (pink) grapefruit than in Marsh when both were grown on sour orange rootstock. The results showed that Florida grapefruit from various sources has high antiscorbutic properties, and in this experiment the average ascorbic acid concentration was 0.40 mg. per cubic centimeter of grapefruit juice.

**Influence of purines, creatinine, and creatine on the oxidation of vitamin C.** K. V. GIRI and P. V. KRISHNAMURTHY (*Nature [London]*, 147 (1941), No. 3715, p. 59).—Supplementing the observations previously noted (E. S. R., 85, p. 705), the authors report, with tabulated data, that the oxidation of vitamin C by  $\text{Cu}^{++}$  at pH 7.2 is completely inhibited by the purines, xanthines, uric acid, and theophylline in a final concentration of 0.00014–0.00017 M, while caffeine and theobromine even at higher concentrations are without effect. Creatine at a final concentration of 0.000095 M had no effect, but creatinine at practically the same concentration, 0.0011 M, afforded almost complete protection. It is suggested that “in addition to glutathione and other thiol compounds which are known to exert similar protective action against the oxidation of vitamin C, the presence of purines and creatinine in the body may insure the existence of reduced vitamin C or prevent the oxidation of the vitamin by  $\text{Cu}^{++}$ .”

**Levels of ascorbic acid in the blood plasma of apparently healthy children.** F. E. HOLMES, G. E. CULLEN, and W. E. NELSON (*Jour. Ped.*, 18 (1941), No. 3, pp. 300–309, figs. 5).—Plasma ascorbic acid levels are reported for a group of 69 institutional children over a 10-mo. period, and a second selected group of 49 children from the same institution, about half of whom were rated high and the other half slightly below average in health and physical development. Data were also obtained from children in a convalescent home and others with infectious and metabolic diseases in a hospital ward. Saturation tests were conducted on 17 of the institution children, 13 of whom had been found to have low and the others high plasma levels. Some of the institution children with low levels were given ascorbic acid in addition to their regular diet in amounts of 50 mg. a day for from 17 to 38 days and then 100 mg. daily for 21 additional days.

Estimated dietary intakes of ascorbic acid ranged from 21 to 122, with an average of 60 mg. daily for the institution children, and averaged 120 and 130 mg., respectively, for the children in the convalescent home and the hospital ward. The most significant observation was the relatively large number of children with low plasma levels in all determinations. No factors were found by physical examination or study of the hemoglobin content to distinguish children with low from those with high plasma values. There was no evidence of seasonal variation as a result of changes in dietary intakes. There were no significant differences in the plasma levels of presumably well children in the institution and the sick children in the hospital. In children with both high and low plasma levels, the values were raised by the administration of ascorbic acid, but the excretion of ascorbic acid following the test dose was (with one exception) much less in the children with originally high than low levels. “No conclusion is drawn concerning the minimal adequate level of ascorbic acid in the plasma. However, if this level is to be considered as 0.6 mg. percent, or even 0.4 mg. percent as suggested by Ralli, then it is obvious that dietary standards should be revised. Particularly should this be the case in planning institutional diets, where there is less opportunity for observation of the individual child's intake.”

**Vitamin C deficiency in an otherwise normal adult, J. H. CRANDON and C. C. LUND** (*New England Jour. Med.*, 222 (1940), No. 18, pp. 748-752, figs. 3).—A normal male subject 27 yr. of age and weighing 158 lb. at the beginning of the experiment subsisted for a period of 4 mo. on a vitamin C-free diet supplemented by the other known vitamins. Plasma ascorbic acid determinations were made daily by the macromethod of Mindlin and Butler (*E. S. R.*, 80, p. 728), and determinations of the ascorbic acid content of the white cells and platelets by the method of Butler and Cushman. Capillary fragility by the Göthlin method, basal metabolism rates, hemoglobin (Sahli), and body weights were determined at frequent intervals. After 85 days on the vitamin C-free diet, an experimental wound was made on the back of the subject and a similar one on a normal control with high blood plasma ascorbic acid, and small portions of the muscle were removed for analysis. On the sixth postoperative day the sutures were removed from both wounds, and on the eleventh day specimens were taken for examination.

During the entire period of the experiment, no sign or symptom of scurvy developed. The plasma ascorbic acid fell rather rapidly during the first 11 days, remaining between 0.14 and 0 mg. per 100 cc. for approximately 28 days and 0 thereafter. The ascorbic acid level of the white cell layer of the centrifuged blood fell from a normal value of 28.0 mg. per 100 cc. on the seventeenth day to 4.0 mg. on the eighty-second day and 0 mg. on the one-hundred and twenty-second day of the diet. The basal metabolic rate fell to -20 percent during a period of losing weight, with somewhat higher values later when the weight losses were checked. A slight fall in red-cell count and hemoglobin about the beginning of the third month was rapidly corrected by an intake of 8 gm. of ferrous sulfate daily. All other tests, including capillary resistance, gave normal values. Subjectively, the only symptom of fatigue was a mild lassitude. No increased fatigue on muscular exertion could be detected in ergograph tests. In spite of the complete absence of vitamin C from the biopsy muscle of the deficient subject, there was no appreciable difference from the control in the healing of the wound.

**Experimental human scurvy, J. H. CRANDON, C. C. LUND, and D. B. DILL** (*New England Jour. Med.*, 223 (1940), No. 10, pp. 353-369, figs. 12).—The experiment noted above was extended to a total of 6 mo. on the controlled vitamin C-deficient diet, with a subsequent period in which an attempt was made to determine the vitamin C requirement of the subject by saturation tests with ascorbic acid.

After 134 days small perifollicular hyperkeratotic papules began to develop over the buttocks and legs and progressed in severity during the next 3 weeks. After 161 days small hemorrhages or petechiae appeared over the lower legs and gradually extended over the lower thighs. At the end of 182 days a second wound was made similar to the first as noted in the preliminary report. On examination 10 days later the skin showed healing, but beneath the skin there were no signs of healing but instead unorganized blood clots, sections of which on examination showed lack of intercellular substances and capillaries. At this time there were no gross changes in the gums or teeth although X-ray films showed interruption of the lamina dura, no anemia, no diminution in capacity for anaerobic work but inability to perform aerobic work, accompanied by a decrease in rate of disappearance of blood lactate, no change in blood complement titer, and no evidence of lowered resistance to infection. The capillary resistance tests were still negative, there was a fall in blood pressure, a lowering of total phosphorus content of the striated muscle, and an increase in phosphagen phosphorus.

Immediately following biopsy after the second wound, daily doses of 1,000 mg. of ascorbic acid were administered intravenously and plasma and urine ascorbic

acid determinations made hourly. On the first day the plasma ascorbic acid content fell very rapidly during the first 3 hr. following the injection, reaching zero at the end of 5 hr. Saturation of the blood occurred between the third and fourth days, but the tissues were not completely saturated at this time, as shown by the urinary excretion. On the basis of the length of time required before the first signs of scurvy appeared and an estimation of from 4 to 6 gm. as the maximal amount of vitamin C required for resaturation, the maximal daily utilization of the vitamin was calculated to be between 30 and 45 mg.

**Experimental human scurvy:** Notes on a remarkable study reported by Crandon, Lund, and Dill, F. W. Fox (*Brit. Med. Jour.*, No. 4182 (1941), pp. 311-313).—The findings in the above noted investigations of Crandon et al. are reviewed and discussed in comparison with those of the author and his associates. Attention is called to the complementary nature of the two investigations and the similarity in the results obtained and the general conclusions drawn. "Taken together, the two investigations lend no support to the assumption, so commonly made, that large amounts of the vitamin would improve the general standard of health, though the precarious nature of such meager supplies is equally clearly demonstrated."

Other conclusions drawn from the review are that in the future more attention should be given to follicular keratosis as the first recognizable sign of scorbutic tendency, that estimation of the ascorbic acid content of the white cell platelet layer of the centrifuged blood appears to be a reliable method of investigating subclinical scurvy, that the role of ascorbic acid as a prerequisite for the formation of intercellular substances has now been definitely established for the human subject, and that ascorbic acid may be concerned with the rate of disappearance of the blood lactate accumulating during the performance of physical work.

**Vitamin C and fatigue** (*Lancet [London]*, 1941, I, No. 12, pp. 386-387).—In this editorial comment, based chiefly on the studies of Crandon et al. and Fox et al. noted above, emphasis is given to the correlation in the findings of the former group of fatigue and weakness following performance tests in progressive vitamin C deficiency with an abnormally low rate of disappearance of blood lactic acid produced by the work, and several lines along which further study is needed are suggested as follows:

"First, what is the rate of improvement on restoring ascorbic acid to the diet? Second, is the mechanism of such a nature that when working normally it can be made more efficient by superadded ascorbic acid? Third, is it such that ascorbic acid is used up, and if so can the immediate supply be replenished more rapidly via the alimentary tract than by mobilization from the store which evidently exists in the body?"

**Ascorbic acid deficiency and enzyme activity in guinea pig tissues**, C. J. HARRER and C. G. KING (*Jour. Biol. Chem.*, 138 (1941), No. 1, pp. 111-121).—The possibility that ascorbic acid in addition to its probable function as a carrier-catalyst in tissue respiration may be of importance as a regulating and protective agent in cellular physiology led to this investigation of the effects of ascorbic acid on the action of two hydrolytic and two respiratory types of enzymes in guinea pig tissues. Liver esterase activity decreased progressively with vitamin depletion to —65 percent in acute scurvy, and the phosphatase activity of intestinal mucosa and kidney cortex was changed to only a moderate degree and of liver and brain to an even lesser extent during scurvy. Succinic dehydrogenase activity of the heart and skeletal muscle showed a marked decrease and cytochrome oxidase activity a moderate decrease in ascorbic acid deficiency.

**Studies on hemoglobin regeneration in patients with vitamin C deficiency**, E. L. LOZNER (*New England Jour. Med.*, 224 (1941), No. 7, pp. 265-268).—Five patients with moderate anemia and with presumptive vitamin C deficiency, as indicated by total absence of reduced ascorbic acid from the plasma, were treated with bed rest and a diet composed of foods containing no more than a trace of ascorbic acid or of the vitamin B complex. In four of these regeneration of hemoglobin took place spontaneously or with the administration of iron alone. It is concluded, therefore, that hemoglobin regeneration may occur in the absence of reduced ascorbic acid from the blood plasma. It is suggested that loss of blood in scurvy, which is essentially a hemorrhagic disorder, may play a role in the development of the anemia accompanying scurvy.

**Vitamin E** (*New York: Chem. Pub. Co.*, 1940, pp. VIII+88, figs. 2).—This monograph contains the texts of papers read at a symposium held under the auspices of the food group of the Society of Chemical Industry, April 22, 1939. The papers have been grouped in three parts consisting, respectively, of four papers on the chemical structure and properties of tocopherol (vitamin E), six on the physiological action of vitamin E and the consequences of vitamin E deficiency, and five on the clinical and veterinary uses of wheat-germ oil and vitamin E preparations.

**Alpha-tocopherol (vitamin E)** (*Rahway, N. J.: Merck & Co.*, 1941, pp. [2]+13).—A supplement to the bibliography noted previously (*E. S. R.*, 85, p. 712).

**Uncomplicated vitamin E deficiency in the rabbit and its relation to the toxicity of cod liver oil**, C. G. and J. B. MACKENZIE and E. V. MCCOLLUM (*Jour. Nutr.*, 21 (1941), No. 3, pp. 225-234).—In an extension of earlier work (*E. S. R.*, 84, p. 713), evidence was obtained that the ingestion of animal fats (particularly cod-liver oil) is not a prerequisite for the production of nutritional muscular dystrophy in rabbits. Severe lesions of the voluntary muscles were produced on a vitamin E-deficient diet containing only 0.5 percent of animal fat, and were prevented by synthetic  $\alpha$ -tocopherol alone. However, the preventive action of the  $\alpha$ -tocopherol was rendered ineffective when cod-liver oil was added to the basal diet or when both the  $\alpha$ -tocopherol and the cod-liver oil were administered orally within a few minutes of each other. Several possible explanations are given of the dystrophic action of cod-liver oil fed separately from vitamin E. The explanation considered most likely is the destruction of the  $\alpha$ -tocopherol by cod-liver oil following the ingestion of the two substances.

**Vitamin K—2-methyl-naphthoquinone (vitamin K-active), vitamin K<sub>1</sub>, vitamin K<sub>2</sub>, other related substances** (*Rahway, N. J.: Merck & Co.*, 1941, pp. [2]+20).—A supplement, dated November 1941, to the previously noted bibliography (*E. S. R.*, 86, p. 429).

## TEXTILES AND CLOTHING

**Wool characteristics in relation to Navajo weaving**, J. O. GRANDSTAFF (*U. S. Dept. Agr., Tech. Bul.* 790 (1942), pp. 36, pls. 2, figs. 19).—According to an abstract submitted by the author, the physical characteristics of Navajo wool, in relation to hand weaving of rugs and blankets, were studied at the South-western Range and Sheep Breeding Laboratory, Fort Wingate, N. Mex., from 1937 to 1939. Small experimental rugs were woven from selected lots of wool produced by a flock of Navajo sheep. In addition, a study of the physical characters of the wool used in the manufacture of 162 old Navajo blankets and rugs, now in museum and private collections, was made. In the first test it was found that Navajo wool of medium fineness, corresponding in average diameter to

commercial Three-eighths Blood, had the most desirable length and proportion of outer-coat and undercoat fibers for the production of rugs with good texture. In the second test with five lots of wool, representing the range in fiber-diameter dispersion ordinarily encountered in Navajo wool of medium fineness, it was found that the proportion and diameter distribution of outer-coat and kemp fibers were more important factors in determining rug quality than average fineness. This conclusion was verified by a third test with wools coarser and finer than the medium grade. The most uniform wool, containing from 7 to 11 percent of fibers between  $40\mu$  and  $50\mu$  in diameter, with fewer than 1 percent of fibers exceeding  $50\mu$  in diameter, invariably produced rugs with the most desirable texture. The low percentage of grease and crimp associated with the fibers of Navajo wool make it desirable for Navajo handicraft methods. Kemp in excess of 2 percent caused the rugs to be uneven in color and harsh in texture. The old blankets and rugs of superior quality were made from fine or medium Navajo wool containing a low percentage of outer-coat and kemp fibers. Workmanship and wear in these old specimens made the effects of variations in wool quality less apparent than in the new rugs experimentally woven. These tests conclusively demonstrated that wools suitable for Navajo handicraft uses should be from an open type of fleece with a low content of natural yolk, a broad crimp, a staple length between 10 and 20 cm., 5-10 percent of fibers more than  $40\mu$  in diameter with maximum uniformity obtainable in wool of this type, and practical freedom from kemp and other medullated fibers.

**Women's measurements for garment and pattern construction.** R. O'BRIEN and W. C. SHELTON (*U. S. Dept. Agr., Misc. Pub. 454 (1941), pp. VI-73, pls. 14, figs. 13*).—This research project, sponsored and supervised by the Bureau of Home Economics from July 1939 to June 1940, was conducted as a series of State Work Projects Administration projects in Arkansas, California, Illinois, Maryland, New Jersey, North Carolina, and Pennsylvania, with the cooperation of local universities and other educational institutions. In this study, carried out by a plan much like that employed earlier in obtaining body measurements of boys and girls (*E. S. R.*, 86, p. 140), weight and 58 body measurements used in pattern and garment construction were taken on each of 14,698 women. The results obtained were subjected to a detailed statistical analysis so planned as to provide data from which the garment and pattern industry can develop a system of sizes satisfactory to consumers and all branches of the trade. The procedure and scope of the study, the data obtained, and the statistical analysis are presented in detail. As is discussed, the analysis showed that girth measurements have little relation to vertical measurements, and that a combination of horizontal and vertical measurements must be used if all the measurements are to be accurately predicted. Height, the most practical vertical measurement, is as accurate a predictor as any other one, but no one girth measurement is as good a predictor of the other girths as is weight. That is, a stature-weight combination would be the best basis for classifying women's body types for the establishment of a standard system of garment and pattern sizes. Figures for setting up such a system are given. Data for alternative systems which would not be so generally satisfactory are also included.

**The importance of clothing in air conditioning.** C. P. YAGLOU and A. MESSER (*Jour. Amer. Med. Assoc.*, 117 (1941), No. 15, pp. 1261-1262).—Surface temperatures of clothing, exposed skin, and skin under the clothing were determined in a series of experiments with healthy men and women in clothing of various weights and exposed to ordinary air conditions in an air-conditioned room. The conclusion drawn from the study is that "differences of comfort

standards between men and women, and individual differences, are largely due to differences in dress and can be reconciled by adjustments of clothing, according to susceptibility to cold or heat. If women would dress in winter with clothes that are comparable in warmth to those of men, they would be comfortable in a temperature of 72° F. instead of 76° F., and there would be less discord over the matter of room temperature. Conversely, if men would take off their vests, coats, and collars in hot weather, buildings would not have to be cooled below 83° F. instead of 76° to 80° F. as at present, and difficulties now experienced with sharp temperature contrasts would be alleviated."

**Hosiery seam position during the Frazier test, E. C. PETERSEN.** (U. S. D. A.). (*Rayon Textile Mo.*, 22 (1941), No. 8, pp. 59-62, figs. 3).—Values for the recovery-stretch ratio ( $r/s$ ), a measure of how well the stocking returns to its original shape, and the stretch load increase for the inch from 19.2 to 20.2 in. ( $s'-s$ ), a measure of the resistance of the stocking to stretching, were obtained in tests using the Frazier machine (1) with the hosiery seam beneath the lower machine jaw and (2) with the seam between the machine jaws. Twelve hose of each of 11 styles of cotton hose were tested, 6 in each position. An analysis of variance was made for the  $r/s$  and  $s'-s$  values secured by both methods. The variation within styles of hose was found to be less and the differences between different styles more significant when the hose had been placed in the machine with the seam between the jaws, and it is considered that in future testing of worn hosiery the seam should be so placed. The relative strength of the portion receiving the most wear and therefore the most likely to break is thus tested.

**Coat making at home, M. SMITH** (U. S. Dept. Agr., *Farmers' Bul.* 1894 (1941), pp. [4] + 27, figs. 35).—This publication, designed to help with the simple technics of tailoring, includes pointers on selecting the pattern and materials, lists necessary or desirable equipment, and tells in detail how to go about making the coat. There are also special sections on fur trim and remodeling.

## HOME MANAGEMENT AND EQUIPMENT

**Improving levels of living of tenant families, D. DICKINS** (*Mississippi Sta. Bul.* 365 (1942), pp. 18, figs. 9; also in *Miss. Farm Res.* [*Mississippi Sta.*], 5 (1942), No. 1, pp. 4-7, figs. 9).—The levels of living of 100 owner families were compared with those of 117 share-renter and 93 sharecropper families. All were young white families residing in poorer agricultural areas of the State and averaging 4.6, 4.8, and 4.4 family members, and \$790, \$577, and \$484, respectively, in yearly incomes. Returns from farming, value of housing and of products furnished by the farm, and money income from nonfarm sources were greater for owner than for tenant families. Returns from farming and value of housing and of products furnished by the farm were greater for share-renter than for sharecropper families, but the latter group had the greater money income from nonfarm sources because of work relief received. Money incomes of share-renter and sharecropper families were about the same (one group earned more from the farm and the other off the farm), but the nonmoney income of the latter group was the lower by about \$100, since they lived in poorer houses, produced less food, and had less frequent increases in inventories. Cash expenditures for family living were about \$100 greater by owner than by tenant families. The two groups of tenant families had about the same cash expenditures, but the share renters spent less for food, since they raised more at home, and so had more to spend for clothing, recreation, and community welfare. Net deficits,

due chiefly to increase in debts for family living, were shown by 34 percent of the owner families, 45 percent of the share renters, and 52 percent of the sharecropper families.

From these findings it is considered that improvement in levels of living of tenant families in such areas would involve (1) more attention to the use to which each acre is put, with receipts from the sale of farm products distributed throughout the year; (2) greater production of food for family consumption; (3) making of simple repairs on buildings and premises; (4) training in nonagricultural pursuits to make possible earnings from nonfarm activities; (5) better understanding of qualities in goods and their use; and (6) a feeling of need for improved standards of living.

**How do farmers adjust to low incomes?** (*Wisconsin Sta. Bul. 453 (1941), pp. 32-33*).—This brief report is based on findings by M. Cowles and I. Head of a recent survey of expenditures of farm families operating farms in several counties in the State.

### MISCELLANEOUS

**Report of the Secretary of Agriculture, 1941, C. R. WICKARD** (*U. S. Dept. Agr., Sec. Agr. Rpt., 1941, pp. VI+245*).—In addition to a summary of findings of the State agricultural experiment stations, the principal findings of the Department are presented. The latter data are noted elsewhere in this issue.

**Report of the Director of the Office of Foreign Agricultural Relations, 1941, L. A. WHEELER** (*U. S. Dept. Agr., Off. Foreign Agr. Relat. Rpt., 1941, pp. 14*).—This report for the fiscal year ended June 30, 1941, describes and discusses the effects of the Lend-Lease Act, the war and agricultural world trade, post-war plans for world agriculture, new services performed by the Office, and its organization and functions.

**Fifty-third Annual Report [of Georgia Station, 1941], H. P. STUCKEY** (*Georgia Sta. Rpt. 1941, pp. 161, figs. 31*).<sup>a</sup>

**Forty-eighth Annual Report [of Minnesota Station], C. H. BAILEY** (*Minnesota Sta. Rpt. 1941, pp. 95*).<sup>a</sup>

**What's new in farm science: Annual report of the director, [Wisconsin Station, 1941], I, compiled by N. CLARK and N. HOVELAND** (*Wisconsin Sta. Bul. 453 (1941), pp. [2]+88, figs. 25*).—This portion of the annual report of the station deals with animal diseases and breeding; animal nutrition; home economics; farm income and welfare; farm engineering; game management; bacteria, molds, and yeasts; and dairy products.<sup>a</sup>

**Methods of correlation analysis, M. EZEKIEL** (*New York: John Wiley & Sons; London: Chapman & Hall, 1941, 2. ed., pp. XIX+531, figs. [91]*).—A revision of the book previously noted (*E. S. R., 64, p. 399*), with the introduction of a chapter on the method of analysis by variance.

<sup>a</sup> The experimental work reported is for the most part noted elsewhere in this issue.

## NOTES

---

**Arkansas University and Station.**—A grant of \$150,000 from the General Education Board for the conduct of a five-State regional study of land tenure and farm labor problems has been announced. The university has been designated as fiscal agent. The research will include field studies of land tenure and farm labor problems in Arkansas, Mississippi, Louisiana, Texas, and Oklahoma. A regional staff, headed by Dr. H. C. Hoffsommer, professor of rural sociology and sociologist at the Louisiana University and Station, will be employed, and a regional research laboratory will be set up at the university on a 3-year basis. The project will be under the direction of the southwestern land tenure research committee, of which Dr. C. O. Brannen, head of the department of rural economics and sociology and assistant director of research, is chairman.

**Colorado College and Station.**—The Colorado Agricultural Research Foundation has been set up at the college as a nonprofit corporation to promote agricultural research. The plan is similar to that of the Wisconsin Alumni Research Foundation. It is expected that the major part of its funds will come from patentable discoveries and inventions of the staff of the college and station, but provision is made for contributions from public-spirited citizens.

**Georgia Station.**—Wallace Kincaid Bailey, horticulturist of the Puerto Rico Federal Station, has been transferred to this station to carry on cooperative peanut studies.

**Iowa College and Station.**—Dr. Frank F. Riecken, associate in soil survey of the Illinois Station, has been appointed research assistant professor of soils. Dr. S. W. Edgecombe, extension associate professor of horticulture, has been appointed associate professor of plant science in the University of Manitoba.

**Kentucky University and Station.**—The resignations are noted of Dr. B. J. Errington as animal pathologist and E. J. Beers as field agent in cream grading. Military leave has been granted to J. D. Foster, inspector in charge of the creamery license section; Dr. Ladd N. Loomis, assistant veterinarian; T. C. Hardesty, field agent in cream grading; R. H. Hageman, assistant chemist; H. F. Miller, assistant in agronomy; and W. C. Templeton, Jr., instructor in farm crops. R. O. Gustafson has been appointed assistant forester.

**Minnesota University and Station.**—G. Leroy Peterson, instructor and assistant in agricultural economics, has been appointed assistant professor of agricultural economics in the University of Connecticut.

**Cornell University and Station.**—Dr. Karl McKay Wiegand, professor emeritus of botany, died March 12 in his sixty-ninth year. A native of New York, he was graduated from the university in 1894 and received the Ph. D. degree in 1898. He was assistant and instructor in botany from 1894 to 1907 and associate professor of botany at Wellesley College from 1907 to 1913. Returning to the College of Agriculture in the latter year as head of the department of botany, he served in this capacity until his retirement in August 1941. He was the author of about 100 papers on the taxonomy of plants and plant geography.

**Nevada Station.**—Preliminary work has begun on a study of methods of extracting rubber from rabbit brush (*Chrysothamnus nauseosus*), a common western desert shrub which contains a high content of rubber.

**New York State Station.**—William G. Walter, assistant in bacteriology, has been appointed assistant professor in bacteriology in the Montana College.

**North Carolina Station.**—A central crops research farm to be located 10 miles south of Raleigh and known as the McCullers Branch Station was authorized by the last legislature for field work in agronomy, horticulture, botany, and entomology. Two research greenhouses were also provided, one for agronomy and one for horticulture.

Dr. W. J. Peterson has been appointed head of the new division of nutrition, physiology, and genetics in the department of animal industry, effective May 1. Dr. E. R. Collins has been placed in charge of extension and coordinator of research and extension programs in agronomy, effective on the same date. Other appointments include L. G. McLean as project leader in nursery and flower research, N. C. Teeter as assistant in agricultural engineering, and R. W. McMillen as assistant in agronomy for small grain breeding work vice W. H. Chapman.

**Oklahoma Station.**—The station has inaugurated a new publication series to be called the V Series and consisting of 4- and 8-page leaflets dealing with food production problems. Elmer L. Hartman, in charge of floricultural work, has entered military service and his duties have been taken over by W. R. Kays.

**Tennessee Station.**—The General Education Board has granted funds for a research project on the economic basis of farm forestry. This will be carried through a period of 3 years or more and will involve the cooperation of all departments of the university which are related to this field.

**Texas Station.**—A tract of 160 acres formerly operated by El Paso County has been acquired for operation as the El Paso Valley Experiment Station. Dr. S. E. Jones has been appointed superintendent. A State fund of about \$5,000 has been granted for an office building, barn, and hay shed. The adaptability of various field, vegetable, and drug crops to the region will be tested.

**Wyoming Station.**—A new project on alfalfa pollinization by honeybees in Wyoming has been authorized and will be carried on by the associate research apiculturist with some student assistance. The purpose of this work is to determine the role of the honeybee in tripping the alfalfa flower and its value as an agent in cross-pollinization. It is also hoped to compare the relative efficiency of the Italian and Caucasian races of honeybees in pollinizing the alfalfa flower.

Another new project is on varieties of Wyoming green vegetables desirable for freezing and manipulative treatment to conserve the maximum amount of ascorbic acid. The agronomy department will grow the vegetables, and the testing will be done by the home economics research assistant.

Robert F. Eslick, assistant agronomist, has resigned to accept a similar position with the Colorado College. Ward Smith has been appointed animal husbandman.

# INDEX OF SUBJECTS

NOTE.—The abbreviations "Ala.", "Conn.[New Haven]", "Mass.", etc., after entries refer to the publications of the respective State experiment stations; "Hawaii" and "P.R.U." to those of the experiment stations in Hawaii and Puerto Rico (University station); and "U.S.D.A." to those of this Department.

- AB preparation, effect of admixtures on its toxic action, 637.
- Abacá—  
diseases in Philippines, 337.  
production in American tropics, U.S.D.A. 772.
- Abies balsamica*, abnormality in, U.S.D.A. 636.
- Abortion—see also Bang's disease and *Brucella abortus*.  
in herds free of Bang's disease reactors, Ind. 87.  
salmonellosis in horses, 677.  
trichomonad, of cattle, Tex. 243.
- Acacia leucophylla*, rust fungus on, 802.
- Acadian contracts in southwest Louisiana, sociological aspects, 549.
- Acanthocephala* in young robin, 391.
- Acanthospyche junodi*—  
control by airplane dusting, 659.  
gustatory reactions, 660.
- Acaulopage stenospora* n.sp., description, 491.
- Aceratagallia sanguinolenta*—  
control, [N.Y.]Cornell 217.  
transmission of specific variety of potato yellow-dwarf virus by, 216.
- Acetic orcein, new stain-fixative for chromosome, 455.
- Acetonemia—  
and albuminuria in dairy cows, 242.  
in cattle, physiologic and metabolic aspects, 242.
- Achillea millefolium*, climatic or regional races, 762.
- Achondroplasia in calves, 177.
- Achromotrichia—  
hydroquinone, a vitamin deficiency, 712.  
inefficacy of pantothenic acid against, 712.  
nutritional, effect of pantothenic acid, 711, 712.
- Acid(s)—  
amino, see Amino acid(s).  
C-atoms in, increase in number, 600.  
fatty, see Fatty acids.  
in seed fats, increase in number with advance in evolutionary position, 600.
- Acidity, organic, studies, Conn.[New Haven]
- Acrobeloides butschlii*, notes, 62.
- Acrodynia—  
fourth factor necessary for cure, Wis. 854.  
rat, relation of pyridoxin, pantothenic acid, and linoleic acid to cure, Ala. 700.
- Acrostalagmus*—  
*bactriosporus* n.sp., notes, 62.  
*obovatus* n.sp., notes, 62.
- Actinomyces*—  
*antibioticus*, new soil organism antagonistic to pathogenic and nonpathogenic bacteria, 170.  
*ipomoea*, notes, N.J. 645.  
*scabies*, notes, 794.
- Actinomycetes, soil, relation to potato scab control, Mich. 643.
- Adelphocoris rapidus*, see Plant bug, rapid.
- Adistemia watsoni*, life history, nearly completed, 809.
- Adobe structures in soils, development, Calif. 296.
- Adrenalin—  
daily injection of male rats with, gonad response, 463.  
injection, blood chloride and phosphorus content, effect on, 126.
- Adrenals in dwarf mice, development, 178.
- Accidium gossypii*, aecial stage of *Puccinia boutelouae*, 641.
- Acdes*—  
spp. on Delaware salt marsh, tidal inundation as limiting factor, 512.  
*vevans* eggs, distribution, 512.
- Acolophides* spp. in Utah, 808.
- Acrobacter*—  
*aerogenes*, CO<sub>2</sub> requirement, 761.  
phosphatase production by, 85.  
strain, action of sulfanilyl guanidine, 386.
- Aerosols, insecticidal, use of fatty acids in, 356.
- African coast fever, transmission by ticks, 815.
- Agallia constricta*, transmission of specific variety of potato yellow-dwarf virus by, 216.

- Ageratum conyzoides* virus disease and tobacco, 202.
- Agonodcrus pallipes*, description, 809.
- Agricultural—
- areas in Frederick Co., classification, Md. 692.
  - census returns, analysis, U.S.D.A. 852.
  - colonization, *see* Land settlement.
  - commodities, fixed prices for, 548.
  - cooperation, principles of, Okla. 402.
  - cooperative in Wales, distribution of profits, 402.
  - credit, current problems in, 400.
  - credit, short-term, use of, Ala. 691.
  - economics—
    - expanding scope, 400.
    - war problems in, U.S.D.A. 844.
  - economy of Colombia, U.S.D.A. 692.
  - efficiency, effect of tenure systems on, 400.
  - engineering, *see* Engineering.
  - experiment stations, *see* Experiment stations.
  - exports, early development, status, and outlook, Okla. 692.
  - extension work, community situation affecting, Mich. 412.
  - holdings in industrial areas, Ind. 106.
  - income and export subsidies, 401.
  - journals, new, 576.
  - labor, hired, U.S.D.A. 852.
  - labor problem of Union of South Africa, 549.
  - labor problem, post-defense, and the Department's responsibility, U.S.D.A. 852.
  - labor research, proceedings of conference on, 404.
  - labor, supply and demand for, Del. 256.
  - labor unions, organizational problems, 401.
  - laborers, long-range outlook for, U.S.D.A. 852.
  - land market, control, 402.
  - land, reconsideration of rent theory as it applies to, 400.
  - legislation, international yearbook, 404.
  - machinery—*See also* Combine(s) and Harvesting.
    - and equipment, Ala. 691.
    - efficiency in use, Ariz. 694.
    - for production and harvesting of sweetpotatoes, 316.
    - needs and current practice, 838.
    - work of Bureau of Agricultural Chemistry and Engineering on, relation to national defense, U.S.D.A. 835.
  - Marketing Service, report, U.S.D.A. 849.
  - planning, progress, 263.
  - policies in unoccupied China since 1937, U.S.D.A. 257.
  - production—
    - and prices, Del. 256.
    - goals for 1942, Okla. 402.
    - in New York, 1866-1940, [N.Y.] Cornell 847.
  - products—
    - and byproducts, industrial utilization, U.S.D.A. 723.
    - cost of production, *see specific crops*.
    - exports, additional data, P.R.U. 287.
    - marketing, *see* Marketing.
    - programs, economic effects, 399.
    - publications, new series, P.R.U. 287.
    - relief, *see* Rural relief.
    - research—*see also* Research.
      - war-time bibliographical aids in, editorial, 721.
    - residues, work of regional research laboratories on, U.S.D.A. 723.
    - science, impacts of war on, editorial, 289.
    - situation, appraisal of national interest in, 399.
    - statistics, U.S.D.A. 549.
    - statistics of Ohio, 262.
    - surplus disposal and school lunch program, U.S.D.A. 555.
    - surpluses, use to overcome nutritional deficits, 260.
    - tenancy, *see* Farm tenancy, Farm tenure, and Land tenure.
    - wastes, activated carbon from, 738.
    - work, coordination by new school of agriculture, Miss. 572.
    - workers' budgets, 402.
  - Agriculture—
    - American, and export trade, Okla. 692.
    - American, and newly developing international situation, 400.
    - American, social effects of war and defense program, 400.
    - and meteorology, 590.
    - changing structure and impacts on labor, 400.
    - climate as limiting factor in South Dakota area, U.S.D.A. 295.
    - county boards of, 263.
    - Department of, *see* United States Department of Agriculture.
    - electricity in, *see* Electricity.
    - financing, textbook, revision, 120.
    - function of credit in, 402.
    - improvement, measures for, 399.
    - in Argentina, 718.
    - in Argentine trade agreement, U.S.D.A. 692.
    - in Great Plains, stability, livestock and forage production as aid, U.S.D.A. 772.
    - in Louisiana, significance of reported trends in, 846.
    - in Manchuria under Japanese control, U.S.D.A. 105.
    - in Russia, effects of World War II on, U.S.D.A. 257.
    - in São Paulo-Northern Paraná Region, U.S.D.A. 105.
    - in Sweden, adjustment to war conditions, U.S.D.A. 847.
    - in Uganda, 542.
    - labor efficiency in, 260.

## Agriculture—Continued.

- modern, function of credit in, 400.
- of American Indians, bibliography, U.S.D.A. 847.
- radiation in, 842.
- Soviet, and Russo-German War, U.S.D.A. 257.
- trade unions in, 550.
- transportation requirements, U.S.D.A. 260.
- tropical and subtropical, recent studies, 718.
- wage determination, methods in, 400.
- war problems, Okla. 692.
- wartime, and post-war objectives, U.S.D.A. 847.
- Agilus ruficollis*, see Cane borer, red-necked.
- Agromyza phaseoli*, relative resistance of cowpea varieties to, 223.
- Air-conditioned rooms, importance of clothing in, 874.
- Air-permeation experiments, powder compactor for, 724.
- Alabama argillacea*, see Cotton leafworm.
- Alabama Station, report, 717.
- Albumin, egg—
  - binding of more than one vitamin by, Wis. 854.
  - thick, characteristics of ovomucin gel, 461.
- Albuminuria and acetonemia in dairy cows, 242.
- Alicaligenes*—
  - phosphatase production by, 85.
  - radiobacter*, crown gall, and hairy root bacteria, comparative physiology, 338.
- Alcohol, power, in tractors and farm engines, 838.
- Alder aphid, woolly, studies, Ga. 807.
- Aldoses, oxidation by hypiodite in methanol, 435.
- Aleyrodidae of Mexico, review, 657.
- Alfalfa—
  - and other legumes, comparative forage production, P.R.U. 318.
  - bacterial wilt resistant strain, U.S.D.A. 771.
  - bacterial winterkilling, Colo. 636.
  - boron deficiency, Wash. 35.
  - boron for, field trials with, 341.
  - breeding, Nebr. 33.
  - dwarf and Pierce's disease of grapevine, association, U.S.D.A. 336.
  - harvesting for artificial dehydration, 838.
  - hay and corn grain, relative net energy values, 515.
  - hay and winter sunshine as sources of vitamin D for pigs, 516.
  - hay, mineral composition, Colo. 662.
  - hybrids, seed development in, 607.
  - injury caused by potato leafhopper, nature of, 808.
  - irrigation tests, Tex. 180.
  - leaf meal, effect on hatchability and egg production, 517.
  - lipids, effect on sweetclover poisoning in cattle, 248.

## Alfalfa—Continued.

- meal, growth-promotion value, Nebr. 76.
  - new strains, U.S.D.A. 774.
  - on neglected hay lands, fertilizer tests, N.H. 317.
  - pollinization by bees, relative efficiency of races of, 878.
  - Rosellinia* root rot of in California, U.S.D.A. 50.
  - seed(s)—
    - Chalcis*-fly infested, method for purity analysis, 622.
    - crops, *Lygus* bugs on, cooperative control, community program, U.S.D.A. 806.
    - impermeability in, persistence in, 600.
    - new wilt-resistant winter hardy, increase of, Utah 469.
    - setting, Nebr. 33.
  - silage, see Silage.
  - snout beetle—
    - biology and ecology, [N.Y.] Cornell 73.
    - control and suppression [N.Y.] Cornell 220.
  - species, comparison in reactions to leafhoppers, 616.
  - strains, instability of resistance to aphids in, 69.
  - varieties, measurements of recovery after cutting and fall dormancy, 182.
  - variety tests, La. 32, Nebr. 33, N.H. 318, Tex. 180.
  - yield and duration, effect of boron, Va. 616.
- Alga, marine, identification of mercerized cellulose in, X-ray diffraction analysis, 167.
- Aklali soils, pH value determination, 440.
- Allergens of agricultural products, special research, U.S.D.A. 723.
- Allieae, in United States, check list, 301.
- Allium coryi*, Texas sp., description and notes, 301.
- Almond(s)—
  - crown gall, chemical eradication, 211.
  - diseases and industry, U.S.D.A. 104.
  - moth, new methods of trapping, 511.
  - stem canker in Buenos Aires, 500.
- Alopecia, mouse, phytin and inositol as curatives, 714.
- Aisophila pomataria*, see Cankerworms.
- Alternaria solani*—
  - defoliation disease of tomato, control, Conn. [New Haven] 50.
  - on tomato, control, relation to flea beetle control, U.S.D.A. 200.
  - spore germination tests of fungicides for, variation in, 340.
- Aluminum, role in phosphorus fixation, 749.
- Alyceclover—
  - new hay and pasture crop, 316.
  - seeding in grain stubble and pastures, Ga. 772.
  - tests, Miss. 467, 772.

## Amaryllidaceae—

alkaloids in and toxicity to *Phymatrichum omnivorum*, 793.

tribe Allieae, in United States, check list, 301.

Amaryllis red blotch, 502.

## Amazon fly—

hosts, rearing large numbers, P.R.U. 66.  
under drought conditions in British Guiana, 361.

*Amblyonma maculatum*, see Tick, Gulf coast.

*Ambrosia artemisiifolia*, notes, 622.

## American—

Country Life Association, notes, 720.

Society of Farm Managers and Rural Appraisers, proceedings, 544.

## Amino acid(s)—

and proteins, metabolism, 413.

aromatic sulfonic acids as reagents for, 440.

content of rice and byproducts, 415.

effect of light on, N.Y.State 435.

in tobacco mosaic virus protein, 796.

metabolism, 123.

nitrogen of, retention by soil, 743.

rate of absorption from small intestine in man, 273.

studies, Conn.[New Haven] 6.

p-Aminozobenzene hydrochloride as insecticide, U.S.D.A. 806.

## p-Aminobenzoic acid—

a vitamin, 711.

chromotrichial activity, 712.

isolation from yeast, 581.

*Amphalius* genus, in North America, 513.

Amphetamine sulfate, effect on gastrointestinal motility in rat, 556.

*Anacetrinus deplanatus*—

attacking sorghum in Kansas, 364.

relation to root and stem rots of barnyard grass, 53, 220.

Anaerobes, classification and determination, manual, 828.

## Analysis—

quantitative, polarographic method, 7.

spectrochemical, shaping lathe for graphite electrodes used in, 724.

Analytical methods, reports of referees on, 437.

## Anaplasmosis—

in cattle, Tex. 243.

studies, U.S.D.A. 676.

transmission by horseflies, 89, Okla. 360.

*Anastatus reduvii* parasite of praying mantid eggs, 812.

*Anastrepha*, genus, studies, U.S.D.A. 661.

## Androgens—

assay, use of chick for, 463.

baby cockerel test for, 463.

chick comb response to, variation in, 463.  
in male rat, pubertal increase in responsiveness to, 769.

response of immature male rat to, 463.

Androgenic substances, potency, molecular-equivalents v. weight-equivalents in, 615.

## Anemia—

equine infectious, immunization, 94.

## Anemia—Continued.

hemorrhagic, in dogs, 533.

infectious, studies, U.S.D.A. 533, 676.

pig, and hog cholera immunity, 93.

*Angiopsora zeae*, identity and distribution on corn, 56.

## Angiosperms—

apomixis in, 607.

types of embryo sacs in, 761.

*Angitia platyptiliac*, parasite of artichoke plume moth, Calif. 507.

*Anguillulina*—

*dipsaci* from tulip root oats, injury to grass and clover seedlings, 492.

*multicincta* and other species on plant roots, 202.

*Aniba roseodora*, notes, 752.

Animal(s)—see also Cattle, Livestock, Mammals, Sheep, etc.

and products, imported, inspection and quarantine, U.S.D.A. 676.

biochemical characters, relation to size, genetics of, 610.

biology, 312.

body, utilization of calcium by, Ga. 854.

breeding—see also specific animals.

experiments, N.H. 225.

progeny test, possibilities in, 313.

chromosomes, see Chromosome(s).

cost of production and relation to land use, P.R.U. 107.

dairy, vitamin A requirements, efficiency of rations, in meeting, Miss. 520.

defense mechanisms, 340.

disease(s)—see also specific diseases.

defense mechanisms in, 124.

laboratory diagnoses, Ind. 87.

relation to human welfare, 244.

resistance in, Tex. 243.

studies, U.S.D.A. 676.

transmitted to man, 383.

transmission to man through milk, 244.

domestic, parasites of, 526.

experimental, abnormal behavior, nutritional deficiency as factor, 383.

fats, see Fats.

farm, gastrointestinal tracts, pH value of contents, 663.

fibers, structure, relation to "particles", 429.

fur-bearing, production on Indiana farms, Ind. 65.

growth and early maturity in, measuring, 515.

heat production in, minimum base value, 514.

hybrid vigor in, physiological nature of, 28.

hybrids, incompatibility between different species, 610.

## laboratory—

John's disease in, 248.

phytopathogenic bacterium fatal to, 796.

nutrition experiments, N.H. 225.

nutrition, relation to minor elements, 23.

## Animal(s)—Continued.

- parasites, *see* Parasite(s).
- production, temperature factors in, 816.
- products, digestibility by minks, 351.
- products, production, value of grass and legume forage and pasture in, U.S.D.A. 774.
- size inheritance, 313.
- specification in, symposium, 312.
- wild, examinations for cattle tick, 365.
- Anonchotaenia rostellata* n.sp., description, 254.
- Anopheles*—*see also* Malaria and Mosquito(es).
- quadrimaculatus* races in United States, 353.
- spp. in Southeastern United States, larval and pupal chaetotaxy and eggs, 213.
- Ant(s)—
  - mound-building, control, Conn.[New Haven] 65.
  - red harvester, studies, Tex. 214.
  - white, *see* Termite(s).
- Antestia lineaticollis*, new braconid parasites of, 514.
- Anthelmintic testing, biological variation and dosage-time-mortality relations in, 383.
- Anthracoptes* n.sp., description, 224.
- Anthonomus grandis*, *see* Bollweevil.
- Antibody formation, effect of sulfanilamide and sulfapyridine on, 678.
- Antigens, specific and common, of dove breeds, 178.
- Antihemorrhagic, *see* Vitamin K.
- Antimony determination using internal indicators at ordinary temperatures, 729.
- Antineuritic vitamin, *see* Vitamin B<sub>1</sub>.
- Antirachitic, *see* Rickets and Vitamin D.
- Antirrhinum* leaf spot disease new to Ceylon, 739.
- Antiscorbutic, *see* Scurvy and Vitamin C.
- Anychus clarki*, studies, Tex. 214.
- Aonidiella (Ohrysomphalus) aurantii*, *see* Red scale, California.
- Aonidiella citrina* and California red scale, morphological difference, 657.
- Apanteles carpatus*, life cycle, 812.
- Aphanomyces*—
  - euteiches* on peas, 208.
  - raphani* affecting white radish, N.J. 797.
  - root rot of sugar beet, effect of phosphate, 345.
- Apelinus mali*, introduction and spread in Spain, 352.
- Aphid(s)—
  - attacking pears in Pacific Northwest, 64.
  - control on upland and sea-island cotton, Ga.Coastal Plain, 216.
  - flights observed in New Brunswick, 217.
  - resistance of alfalfa strains to, instability of, 69.
  - studies, Tex. 214.
  - western, studies, 809.
- Aphididae—
  - in Siam and Indo-China, 353.
  - of Nevada, new genus and species, 217.
- Aphidius pistivorus* n.sp., description, 813.
- Aphis gossypii*, *see* Cotton aphid.
- Aphis rumicis*, *see* Bean aphid.
- Apiary inspection, Conn.[New Haven] 64, Tex. 214.
- Apomixis in angiosperms, 607.
- Apotettix eurycephalus*, chromosomal translocations and viability in, 766.
- Apparatus—
  - for diagnosis of *Trichomonas fetus* infection, 387.
  - for measuring noncapillary porosity of soil on extensive scale, 594.
  - for mincing tissue, 87.
  - for separation of soil minerals, 296.
  - for soil solution extraction, 593.
  - for testing flameproofed fabrics, 286.
  - for washing plant tissue, 455.
  - improved automatic continuous percolator, 723.
  - magnetic stirrer for moisture-transfusion cups, 723.
  - powder compactor for air-permeation experiments, 724.
  - shaping lathe for graphite electrodes, 724.
- Apple(s)—
  - alternate bearing in, effect of leaf-fruit ratio, 780.
  - aphid, woolly, control, 64.
  - assimilation of plant food in, effect of leafhoppers, Ind. 65.
  - biennial bearing, control, U.S.D.A. 776.
  - bitter pit, pot experiments on, 647.
  - bitter pit, studies, N.H. 337, 347.
  - blotch control with eradicant fungicides, Tenn. 798.
  - bordeaux spray russetting on, origin and histology, 500.
  - coloring, effect of sodium thiocyanate, Nebr. 42.
  - Cortland, storage quality, 194.
  - crab, *see* Crab apples.
  - Delicious, fruit set, effect of branch ringing before and after blossoming, 193.
  - diseases control, N.C. 51.
  - dusting and spraying, Ind. 42, 65.
  - effect of fertilizers on bud formation and fruit setting, Vt. 326.
  - eye rot associated with *Botrytis cinerea*, 798.
  - fire blight, cause and control, 59.
  - fire blight in New Hampshire, U.S.D.A. 201.
  - fruit set, effect of scoring and spraying, 780.
  - fungicides, new, tests, Conn.[New Haven] 51.
  - Golden Delicious, protection against loss of moisture in storage, 45.
  - harvest sprays for, 782, U.S.D.A. 776.
  - in storage, responses to ploidlin liners and wrappers, 782.
  - Jonathan, effect of borax on storage quality, 332.
  - keeping quality, effect of potassium fertilizers, Vt. 326.

## Apple(s)—Continued.

- leaf variegation, 798.
- leaves, effect of soil moisture on photosynthesis, respiration, and transpiration, 320.
- maggot—
  - biological studies, 361.
  - control, Conn. [New Haven] 64.
  - toxicological studies, 361.
- magnesium deficiency in New Zealand, 331.
- McIntosh—
  - and Wagener, analysis of development, 193.
  - premature drop, reducing, Conn. [New Haven] 51.
  - premature drop, effect of sprays, 193.
  - premature drop, naphthaleneacetic acid for prevention, Vt. 326.
  - response to improved subsoil aeration, 44.
- nutrition, 192.
- orchard(s)—
  - cultivation-cover crop v. sod-mulch culture, 20 yr. results in, Mich. 626.
  - leaf analysis and apparent response to potassium, 627.
  - soil moisture in, effect of cultural treatments, Nebr. 42.
- pests control and oil deposits, 355.
- powdery mildew, studies, 798.
- premature drop—
  - causes and control, [N. Y.] Cornell 45.
  - effect of plant hormone sprays on, 331, 483.
  - prevention, spray demonstrations in Iowa, 331.
  - prevention with naphthaleneacetic acid, 781.
  - spraying for control, 780, 781, Mass. 45, N.C. 42.
- redbug, pyrethrum dusts for control, N.Y. State 651.
- riboflavin content, 869.
- root rot resistance, Tex. 202.
- roots, resistance against frost, effect of scion variety, 482.
- rootstocks, development from domestic sources, U.S.D.A. 776.
- rootstocks, Mailing types, cold hardiness of, 481.
- scab control, Ind. 51, N.H. 209, N.Y. State 490.
- scab control, new methods, 348.
- scab, spraying for, N.H. 337, Vt. 337.
- seedlings, failure to respond to vitamin B<sub>3</sub>, 43.
- shortened, intensive summer spray program for, N.Y. State 652.
- size and yield, effect of supplemental water, Nebr. 42.
- Snow and McIntosh, annual bearing, Wis. 330.
- soft scald, 490.

## Apple(s)—Continued.

- sprayed with natural cryolite, wetting agents for removal of fluorine residue from, 356.
- spraying, use of sulfur preparations in, 647.
- Starking, pollination experiments, 330.
- stocks, clonal, compatibility tests, N.Y. State 477.
- stocks, domestic, v. French crab seedlings, 481.
- stocks, seedling, effect on the size of resulting trees, 44.
- storage—
  - in controlled atmosphere, [N.Y.] Cornell 102.
  - ozone in, 348.
  - scald development, effect of time of harvest, 194, 500.
  - studies, N.H. 326.
- terminal-shoot growth stimulated by Virginia Crab and Hibernial intermediate stocks, 44.
- tests, Nebr. 42.
- thinning, continuous, for period of 20 years, 331.
- thinning experiments, 331.
- trees—
  - blooming, Elgetol for control, N.H. 326.
  - double-worked, correlation of 'runk' circumference with weight of top, 627.
  - effect of concentrations of oxygen and carbon dioxide in soil atmosphere, 450.
  - effect of November 1940 blizzard, 326.
  - life processes, effect of excess water in soil, 193.
  - on selected rootstocks, wind damage to, 483.
  - photosynthesis, transpiration, and growth, effect of oxygen and carbon dioxide in soil atmosphere, 482.
  - ringed branches, relative carbohydrate and nitrogen concentration in new tissues on, 780.
  - young, cultural practices, 780.
- use of hormone sprays on, N.H. 326.
- varieties —
  - and important producing sections of United States, U.S.D.A. 627.
  - cold hardiness of seedlings, 482.
  - European, used as trunk formers, nursery behavior, 482.
  - notes, Miss. 477.
  - on clonal rootstocks, behavior, N.Y. State 477.
  - on Mailing IX rootstocks, performance, 44.
  - prices, as factor in variety selection, [N.Y.] Cornell 261.
  - yields, Miss. 776.
- Washington marketing in Los Angeles, Wash. 851.

## Apple(s)—Continued.

- Washington, on New York and Chicago fruit auctions, Wash. 850.
- waxing treatments, effect on storage quality, 46.
- work of regional research laboratories on, U.S.D.A. 723.
- yield on Ilbernal and Virginia Crab stocks, 330.

## Appraisal—

- Institute of Canada, proceedings, 544.
- rural, papers on, 544.

## Apricot(s)—

- effect of carbon dioxide in transportation and storage, 195.
- Royal, cross of short chilling requirement, origin and transmission of characteristics, 332.
- systemic arsenic toxicity on old apple land, U.S.D.A. 636.
- waxing experiments, 44.

## Arabo-galactan, constitution, components and position of linkage, 580.

Archips (*Cacoezia*)—

- argyrospila*, *see* Fruit tree leaf roller.
- rosaceana*, *see* Leaf roller, oblique-banded.
- Aridelus* spp., parasites of *Antestia lineatocollis*, 514.

## Arkansas Station, notes, 144, 573, 719, 877.

## Arkansas University, notes, 573, 719, 877.

## Armillaria mellea—

- artificial inoculation of plants with, 200.
- cultures from western white pine, variation in, 61.
- growth rate, 61.

## Armyworm—

- numbers captured at light traps, 75.
- southern, buffer capacity of blood of sixth instar, 220.
- southern, glycogen in blood cells and other tissues, 360.
- southern, use of nitrogenous and carbohydrate substances by, 811.

## Arsenic—

- accumulation in Sudan grass and bush bean, 604.
- determination using internal indicators at ordinary temperatures, 729.
- in natural phosphates and phosphate fertilizers, U.S.D.A. 597.
- ingestion and excretion in man, 215.
- toxicity of peach and apricot on old apple land, U.S.D.A. 636.

## Art, rural, expressions of, 698.

## Arteriosclerosis in cattle associated with pulmonary ossification, 530.

## Artesian wells in Las Vegas area, Nev., underground leakage from, 687.

## Arthritis—

- brucellosal, chronic, atrophic type, 528.
- micro-organisms causing, isolated from healthy white rats, 677.
- subacute, of streptococcal origin, in silver fox, 534.

## Artichoke(s)—

- aphid, notes, Calif. 507.
- diseases, notes, Calif. 507.

## Artichoke(s)—Continued.

- globe, pests injurious to, Calif. 507.
- levulose from, 737.
- plume moth, studies, Calif. 507.
- tests, Nebr. 33.

## Asbestos, preparing for filtering mats, 584.

## Ascarid eggs—

- hatching in vitro, 827.
- in swine, survival in cultivated soil, 383.
- Ascaridia lineata* in vitro, viability, effect of duodenal mucus of dogs and pigs, 828.

## Ascochyta—

- on sorghum in Mississippi, U.S.D.A. 336.
- pisi* blight-resistant pea pods, 346.

## Ascomycetes—

- new or little known, collected in São Paulo, 752.
- of Georgia, U.S.D.A. 203.

Ascorbic acid—*see also* Vitamin C.

- concentration in plasma during treatment of infantile scurvy, 713.

## deficiency—

- and enzyme activity in guinea pig tissues, 872.
- determination, 580.
- in laying hens, effects, 666.
- in blood plasma of institutional children, 870.
- in cowpeas, relation to temperature, 606.
- in cow's milk during pregnancy, 522.

   leaf blades, stomatal frequency, relation to transpiration rate, 758.  
   leaf variegation in, inheritance, 764.

## Bean(s)—Continued.

leaves, migration of injected radiophosphorus from, 22.

## lima—

anatomy, 750.  
effect of boron on plant growth and dry seed yield, 778.  
freezing, Ga. 723.  
frozen, quality in, 552.  
green cotyledon, new character in, 458.  
management practices with, Calif. 694.  
seed treatment and spraying and dusting, N.Y.State 490.  
spraying and dusting on Long Island, N.Y.State 646.  
varieties and breeding, Miss. 770.  
varieties, fertilizers, and culture, Ga.Coastal Plain 188.  
variety tests, Nebr. 42.

market diseases of, U.S.D.A. 796.

mosaic and bean yellow mosaic in Brazil, 646.

mosaic control by resistant varieties, N.Y.State 490.

mosaic, genetic study, 311.

polo, varieties, Miss. 477.

response to seed treatments with hormones and mercurials, 622.

root formation, factors affecting, 755.

rust, resistance to six physiologic races, inheritance, 493.

rust studies, 788.

selection for disease resistance, Ga. 759.

snap, developed by station, and commercial varieties, comparison, Ala. 623.

snap, variegation in, genetic studies, 458.

snap, varieties and breeding, Miss. 776.

Somerset, use of protein by rats and sheep, 226.

string, fertilizer tests, Miss. 776.

Tendergreen, fertilization and culture, Ga. 770.

varieties, yields, Miss. 770.

virus 2, isometric crystals produced by, 58.

Bedbug, ecology, 808.

Bedding, survey on State laws and judicial decisions on, U.S.D.A. 717.

## Bee(s)—

activities of, Tex. 214.

combs, moth pests of, 513.

developing, carbohydrate and glycogen content, 661.

effect of stock on production and supercedure, 223.

foulbrood, *see* Foulbrood.

heavy losses, extent and causes in Utah, U.S.D.A. 806.

losses from poisons in Utah, 513.

new dufoureae, from California, 812.

oriental, characteristics in China, 364.

queen, introduction, treatise, 223.

queen, rearing for resistance to American foulbrood, Tex. 214.

winter losses in Ohio, Ohio 75.

Beech growth study by dendrographic method, 635.

## Beech—

changes in during freezing and storage, Ind. 6.

cooking time and tenderness, effect of metal skewers, 121.

graded and branded, retailer and consumer reaction, Ill. 267.

heated before freezing and storage, tenderness, U.S.D.A. 662.

meal, value for foxes, 368.

muscle, iron of, availability, effect of heat, 556.

## production—

effect of feed and effect of sex on, U.S.D.A. 662.

feed, mineral, and vitamin requirements for, U.S.D.A. 662.

grain v. grass in, 225.

silage v. concentrates for, 366.

Sudan grass grazing v. sorgo silage for, Tex. 226.

quality, factors determining, 78.

Beehives, electric heating, 304.

## Beet(s)—

betanin and sucrose in, factors affecting, 478.

effect on succeeding corn crop, N.Y.State 477.

fertilizers for, N.Y.State, 477.

field or fodder, *see* Mangels.

improvement, Conn. [New Haven] 41.

insects in Italy, control, 352.

labor problems, Colo. 696.

leaf spot, spraying methods, 493.

pulp, dried, v. freshly chopped mangel beets for milk and fat production, 671.

roots, color, effect of season of growth, Conn. [New Haven] 41.

seed, pregermination chilling treatment, effect on germination, Conn. [New Haven] 32.

sucrose percentage in, inheritance of factors for, 704.

sugar, *see* Sugar beet(s).

tops as additional roughage for cows, value of careful handling, Colo. 669.

tops, feeding value, 323.

workers, contract, income levels, Nebr. 411.

Belladonna diseases, control, U.S.D.A. 336.

*Benama hutsoni* n.g. and n.sp., parasite of cotton leaf roller, 514.

## Bentgrass(es)—

breeding work, U.S.D.A. 771.

improved, U.S.D.A. 771.

Rhode Island, seed treatments with phytohormones and talc, effect, 40.

Benzene, methoxyl derivatives of, polyploidogenic activity, 454.

Benzimidazole derivatives, identification, 435.

Benzoic acid and diacetyl, comparative bactericidal action, 790.

## Bermuda grass—

new strains, U.S.D.A. 774.

## Bermuda grass—Continued.

sources of P and single v. split applications of N for, Ga. 772.

Tift, characteristics, 470.

Bermuda-lespedeza pasture production, fertilizers and limestone for, Ga. 772.

Berries, *see* Fruits, small, and Raspberry(ies), Strawberry(ies), *etc.*

Bevier, Isabel, pioneer in home economics education and research, editorial, 577.

weed problem, 475.

## Bindweed—

control, Kans. 475, Nebr. 33, N.Dak. 325, U.S.D.A. 772.

control, implements for, Ind. 97, Nebr. 98.

eradication, use of tetrachloethane in, 470.

studies, Kans. 475.

## Biochemistry—

annual review, 413.

clinical applications, 123.

## Biological—

oxidations and reductions, 123, 413.

research, recent, and vitamins, 452.

specimens related to agriculture, preserving, special research, U.S.D.A. 723.

Biology, application of radioactive indicators in, 123.

Biotic communities of Kaibab Plateau, Arizona, 450.

## Biotin—

and growth of *Fusarium avenaceum*, 603.

and growth of *Neurospora*, 165.

identity with vitamin H, 11, 12.

relation to achromotrichia, 711, 712.

Birch posts, preserving, Conn.[New Haven] 49.

## Bird(s)—

and mammals, fertility in, 460.

autopsies at Wildlife Disease Research Station in Utah, 392.

blood parasites, of District of Columbia region, 391.

British, handbook, 651.

combating objectionable roosts of, 351.

ectoparasites of, in British Columbia, 353.

epigamic sex reversion in, 614.

game, studies, Mo. 650.

homeothermy in, development, 232.

in garden, how to attract them, 212.

karyotypes of, 613.

life, role of territory in, 651.

living, removing gizzard contents from, 666.

nesting, analysis of losses in, 805.

of North and Middle America, 351.

## Bird(s)—Continued.

- shore, food habits, 212.
- susceptibility to equine encephalomyelitis, 528.
- western, field guide, 351.
- wild, autopsies on western lake areas, 243.
- wild, carriers of *Hexamita meleagridis*, 537.

## Biscuits, quick frozen, 552.

## Bisulfite-binding substances in blood of children, 860.

## Bitterweed—

- consumption by cows, effect on milk, Miss. 83.
- control in pastures, Miss. 520.
- control, rotation grazing and pulling for, Tex 181.

## Black scale control in olive orchards, 657.

## Blackberry varieties, chromosome studies, 460.

## Blackhead of turkeys, mapharsen therapy in, 538.

*Blattella germanica*, see Cockroach, German.*Blissus hirtus*, see Chinch bug, hairy.*Blissus leucopterus*, see Chinch bug.

## Blister beetle, black, biology, 810.

## Bloat colic in horses, P.R.U. 87.

## Bloat in steer calves, U.S.D.A. 676.

## Blood—

- albumin for use as emulsifier, N.Y.State 651.
- and meat spots, cause and occurrence, 517.
- cells, human, synthesis of flavin-adenine dinucleotide from riboflavin by, 278.
- coagulation, biophysical characters, and formed elements, 124.
- donors, response to iron, 706.
- films, thick, permanent stained preparations of, 333.
- nicotinic acid in, 735, 868.
- of chickens affected with cecal coccidiosis, studies, 390.
- of donors at Paris transfusion center, vitamin A in, 707.
- of high school girls, studies, 555.
- pantothenic acid in, assay method, 442.
- plasma, potassium in, microdetermination, 438.
- prothrombin determination in, modified technic for, 589.
- prothrombin time, effect of intramuscular injection of sodium citrate, 705.
- pyruvic acid in, determination in presence of acetoacetic acid, 13.
- red cell volume circulating and total determined by radioactive iron, 863.
- regeneration, see Hemoglobin.

## Blowfly(ies)—

- effect of pyrethrins, 352.
- loci of olfactory end-organs in, 222.
- sheep, natural control in South Africa, 362.

## Blueberry(ies)—

- breeding, N.C. 42.
- budmite, survey in North Carolina, 224.

## Blueberry(ies)—Continued.

- cultivated, effect of soil temperature on growth, 783.
- culture, N.Y.State 477.
- fertilizer, dates for applying, 47.
- high-bush, effect of severity of pruning, 630.
- improvement and propagation, N.H. 326.
- methods of expressing fruit size, 631.
- plants, growth, effect of lime applications, 47.
- varieties, Ga.Coastal Plain, 188.
- varieties, classification, leaf characters as basis, 631.
- yield and survival, effect of mulches and fertilizers, 783.

## Bluegrass—

- bulbous, germination of bulblets, 617.
- determining pure seed content, 622.
- improved, U.S.D.A. 771.

## Kentucky—

- and Canada, distribution, 319.
- breeding, U.S.D.A. 771.
- experiment in mixing and sampling, 622.
- nitrogen in, range and relation to flowering date, 471.
- nutritive value, rat tests of, U.S.D.A. 662.
- seed treatments with phytohormones and talc, effect, 40.
- pastures, cows' urine as fertilizer for, 233.

## Bluetongue virus, susceptibility of cattle to, 382.

## Bobwhite, see Quail.

*Boletus brevipes*, in southern California, 450.

## Bollworm—

- control, cryolite and cryolite-sulfur mixtures for, 67.
- control, effect on yield, 66.
- control, presquare mopping experiments, N.C. 65.
- control, spraying v. dusting, 73.
- effect of calcium arsenates, 67.
- insecticides for, comparison, 66, 67, 68, 72.
- insecticides or combinations of, tests, 653.
- studies, Ga. 807, Ga.Coastal Plain 216, Tex. 213.
- topping cotton in early fall as possible control, 811.

## Bollworm—

- insecticides for, comparison, 66, 67.
- oviposition and survival of larvae, relation to moisture in cotton, 660.
- pink, advances in control, 352.
- pink, control, P.R.U. 660.
- pink, formation of resting larvae, 74.
- pink, insecticides for control, 74.
- pink, notes, Tex. 213.
- pink, secondary hosts, 660.
- studies, Ga.Coastal Plain 216, Tex. 213.

## Bone—

- calcification, sources of phosphorus for, 125.

## Bone—Continued.

- growing, calcification in, 705.
- preparing sections without decalcification, method for, 382.

Books, importance in rural communities, 698.

## Books on—

- agriculture, financing, 120.
- animal biology, 312.
- avitaminoses, revision, 567.
- bees, queen, 223.
- birds, British, 651.
- birds in garden, how to attract them, 212.
- birds, western, 351.
- botany, 300.
- butterflies of United States, northeastern region, 357.
- climatology, physical, 294.
- consumer education, 120.
- correlation analysis, methods, 876.
- dairy industry of New York, history, 261.
- electrification, rural, 120.
- endocrinology, 242.
- farm management, forestry in, 266.
- fishes, warm water game of United States, 351.
- flowers and flowering plants, 163.
- foods and food customs, Hawaiian and Pacific, 121.
- food buying and our markets, 120.
- food for young children, 124.
- foods in health and disease, use, 124.
- gladiolus, 197.
- home decoration, 572.
- life science, 699.
- livestock, types and market classes, 226.
- malaria, human, 221.
- meat, vitamins in, 560.
- meteorology, 590.
- milk industry, 699.
- nematology, 500.
- oxidation enzymes, 703.
- photosynthesis, 605.
- plant diseases, 336.
- plant ecology, 20.
- plant life, 300.
- plant life of Oregon, 20.
- plant physiology, 601.
- sugarcane industry in West Indies, 474.
- trees, shade and ornamental, maintenance, 785.
- undulant fever, 247.
- vitamin E, 873.
- wildlife, American, 804.

Bookworms, studies, 217.

*Boophilus annulatus*, see Tick(s), cattle.

## Bordeaux mixture—

- and cube, compatibility, 355.
- effect on water loss from inert surfaces, 200.
- lack of uniformity in, 328.
- tests, Ga.Coastal Plain 201.
- toxicity to potato leafhoppers, 69.

## Boron—

- available, effect of soil treatments, 599.

## Boron—Continued.

## deficiency—

- in sugar beets, effect on seed production, 324.
- of alfalfa, Wash. 35.
- of North Carolina soils, N.C. 16.
- relation to internal cork disease, Conn.[New Haven] 16.
- studies, field trials with, 341.
- effect on yields of peanuts, N.C. 34.
- fixation and availability in soil, effect of lime and organic matter, Vt. 296.
- in fertilizers, spectrochemical analysis, 732.
- in pecan nutrition, 334.
- in tomato production, 479.
- nutritive relations to plants, 603.
- starvation of plants, control, 161.

## Botanical—

- bibliography of Argentina, I, contribution to, 601.
- specimens, permanent deep chamber mounts of, preparation, 455.

## Botany—

- college, textbook, 300.
- of New York State, bibliography, 751.

## Botfly(ies)—

- biological habits and control, Mo. 75.
- sheep, life cycle and incidence in New Mexico and Texas, 93.

*Botryodiplodia theobromae* on rubber trees, 804.

## Botrytis—

- blight of tulips, Conn.[New Haven] 51.
- cinerea*, creolin dust for control, 492.
- cinerea*, host plants, 798.
- crown rot of iris, 801.
- induced disease of beans in Great Britain, 797.
- narissicola*, notes, 349.
- sp., spore germination tests of fungicides for variation in, 340.
- tulipae* on tulips in Argentina, 503.

*Bovicola bovis*, see Cattle biting-louse.

## Boys—

- American, body measurements for garment and pattern construction, U.S.D.A. 140.
- basal metabolism, 272.
- school-age, clothing for, Miss. 571.

Brachydactyly, hereditary, in rabbit, embryological development, 461.

*Brachylaemus malayensis* n.sp., description, 530.

## Brachyrhinus—

- ligustici*, see Alfalfa snout beetle.
- sulcatus*, see Vine weevil, black.

## Bracken—

- distribution, in British Columbia, and red-water disease of cattle, 248.
- poisoning, 383.

Brandy industry in California, Calif. 293.

## Bread—see also Flour.

- enrichment, baker's A B C on, 709.
- loaf volume, effect of concentrations of papain and potassium iodate, 855.

**Bread—Continued.**

national flour for, British M. R. C. specifications, 553, 554.

"staff," from peeled wheat, 554.

Breads, vitamin-rich, recipes, Mich. 700.

Breeding, *see* Animal breeding, Plant breeding, and specific animals and plants.

Brine fly, food habits, 353.

*Briosa azaleae* n.comb., 789.

Bromate, use, in volumetric analysis, 729.

**Brome grass—**

breeding, Nebr. 33.

pasture, studies, 470.

smooth, at stages of maturity, composition and digestibility, 292.

smooth, bulk emasculation and pollination, 617.

smooth, seed production, effect of nitrogen, 319.

v. native grass, palatability for sheep, Nebr. 33.

variety tests, Nebr. 33.

*Bromelia pinguin* as source of proteolytic enzymes, P.R.U. 287.

Bronchitis, infectious, virus, modification by egg propagation, R.I. 634.

**Brooder(s)—**

electric, insulated, in uninsulated poultry houses, Nebr. 98.

home-made electric, design for, Wis. 835.

house experiments, Wis. 835.

new electric lamp, description, Ohio. 843.

outdoor, heating studies, 843.

Broomcorn, variety tests, Tex. 180.

**Brucella—**

*abortus*—*see also* Bang's disease.

and *Br. melitensis*, heat-killed vaccines, active immunization of mice and rats with, results, 88.

and relation between blood and whey titers in udder, 242.

*Br. melitensis*, and *Bacillus typhosus*, mixed vaccine, active immunization of humans with, results, 88.

electrophoretic mobility, effect of dissociation, 680.

infection of cows, blood picture, effect of parturition, 530.

infection, relation to periodic ophthalmia, 528.

infection, relation to vitamin A in fetal livers, 527.

strain 19, stability of reduced virulence exhibited by, 242.

strain 45, inability to infect non-pregnant cattle, 247.

antigens, treatment of brucellosis with, 247.

dissemination, role of cockroach and flies in, 527.

electrophoresis studies, 309, 384.

infection, diagnosis, cytophagic reaction used in, 527.

infection in mice, effect of sulfanilamide and sulfamethylthiazol on, 246.

isolation from milk, 527.

**Brucella—Continued.**

laboratory infections due to, 527.

*melitensis* and *Br. abortus*, heat-killed vaccines, active immunization of mice and rats with, results, 88.

*melitensis*, *Br. abortus*, and *Bacillus typhosus*, mixed vaccine, active immunization of humans with, results, 88.

spp., infection of chick embryos by, 384.

**Brucellosis—**

clinical and subclinical, 247.

conquest in animals and its relation to human health, 247.

in bulls and swine, 87.

in horses and goats, 243.

treatment with *Brucella* antigens, 247.

*Bruchus bruchialis*, *see* Vetch bruchid.

Brussels sprouts production, starter solutions in, 624.

Budget law, uniform, results for Texas counties, Tex. 696.

**Budmoth—**

control, insecticides for, N.Y.State 660.

eye-spotted, profoliage treatments for, N.Y.State 652.

**Buffalo grass—**

breeding, Tex. 180.

culture tests, Tex. 180.

new strains, U.S.D.A. 774.

pasture, establishment, Tex. 181.

seed, production and germination, Tex. 181.

v. Sudan grass on dry land and under irrigation, Tex. 181.

Bulb mite on narcissus, control, U.S.D.A. 807.

**Bulb scale mite—**

on narcissus, control, U.S.D.A. 207, 807.

studies, 224.

**Bull—*see also* Sire(s).**

semen bacteriology, 520.

semen, studies, 708.

spermatozoa, phospholipids as source of energy for motility, 768.

spermatozoa, sources of energy for, 316.

Bunt, *see* Wheat smut, stinking.

**Bureau of—**

Agricultural Chemistry and Engineering, work of, relation to national defense, U.S.D.A. 835.

Agricultural Economics, marketing research program, relation to work of experiment stations, 260.

Agricultural Economics, report, U.S.D.A. 104, 845.

Animal Industry, experiments in animal genetics and physiology of reproduction by, U.S.D.A. 609.

Dairy Industry, report, U.S.D.A. 519.

Bursaceae, systematic anatomy of woods of, 760.

**Butter—**

consumer reactions to grades and characteristics, Ind. 80.

distribution of salt in and effect on bacterial action, 377.

from flash pasteurized cream, phosphatase reaction of, 85.

## Butter—Continued.

- hardness, factors affecting, Tex. 233.
- Indiana, quality, Ind. 80.
- keeping qualities, Ind. 80.
- keeping quality, index to, 380.
- making, holding cream for, S.Dak. 240.
- making in South, cream for, 373.
- phosphatase value, effect of acidified milk cans, 675.
- salted and unsalted, flavor development in by micro-organisms, 673.
- salted, flavor development by pure culture of bacteria, Iowa 379.
- tallowiness in, cereal antioxidant for prevention, 240.
- vitamin A potency, relation to chemical analyses, 442.

Buttercup, Persian, root rot of, cause, 802.

## Butterfat—

- and refined coconut oil, nutritive value, comparison, 269.
  - carotene in, relation to oxidized flavor, 523.
  - carotenoids in, relation to those in silage rations, 237.
  - color, effect of feeding fat soluble dyes to cows, Mich. 82.
  - determination, effect of rancidity in milk, Mich. 9.
  - effect of soybeans and soybean oil on production and quality, 377.
  - extracted, choline in, Ind. 80.
  - production, dried beet pulp v. freshly chopped mangel beets for, 671.
  - secretion, effect of thyroxine administration on blood lipoids and on nature of fat, 821.
  - test affected by feeds, Ind. 80.
  - vitamin A content, effect of vitamin A intake, 522.
- Butterflies of United States, northeastern region, handbook, 357.

## Buttermilk—

- cultured, flavor development in by micro-organisms, 673.
- quality, factors affecting, 240.

Button top midge, fluctuations in population, 214.

*Byturus unicolor*, see Raspberry fruitworms.

## Cabbage—

- black rot, studies, Tex. 202.
- breeding, Tex. 189.
- caterpillars, control in South, insecticides for, U.S.D.A. 659.
- Chinese, leaf spot on, U.S.D.A. 201.
- enterprise, costs and returns, [N.Y.] Cornell 405.
- fertilizer placement for, N.Y.State 477.
- fertilizer tests, Ga. 776, Miss. 478, 776, Ohio 189.
- juice, germicidal action, N.Y.State 550.
- looper, control, Conn.[New Haven] 65.
- looper, studies, Tex. 214.
- looper, timing treatments for, 73.
- maggot control, Conn.[New Haven] 64, 65.
- maggot, control, relation to blooming time of dogwood, N.C. 65.

## Cabbage—Continued.

- molds in markets, 639.
- shape index, charts for computation, 41.
- tetraploid, colchicine-induced, 763.
- varieties, comparative cold resistance, Ala. 623.
- varieties, fertilizers, and culture, Ga. Coastal Plain 188.
- varieties for truck growers, Miss. 42.
- variety tests, Ga. 776, Miss. 776.
- yellows-resistant strains of kraut and Danish, improvement, N.Y.State 490.

## Cabbageworm(s)—

- control, Tex. 214.
- imported, control, Conn.[New Haven] 65.
- imported, timing treatments for, 73.
- possibilities of biological control, 352.
- rottenone sprays for, N.Y.State 652.

## Cacao—

- capsid pests in Nigeria, 217.
- culture and economic promotion in Caldas, 783.
- culture, diseases and pest control, 783.
- periodicity in witches'-broom formation by, 203.

*Cacoecia*, see *Archips*.

## Cactus(i)—

- destroying insect, Colo. 651.
- pricklypear, control on short-grass range, 323.
- southwestern, studies, 20.
- spineless, production tests, Tex. 189.

Cakes, quick frozen, 552.

Cakes, vitamin-rich, recipes, Mich. 709.

*Calamagrostis epigeios* in Wisconsin, 36.

Calcification and ossification, 705.

## Calcium—

- and phosphorus metabolism, effect of fat, 558.
- and phosphorus metabolism, studies, 272, Conn.[New Haven] 123.
- arsenates, different, effect on cotton insects, 67.
- chloride solutions in intestine, changes in composition, 862.
- deficiency, severe, in growing rats, 866.
- from green leaves containing oxalates, utilization, Conn.[New Haven] 123.
- in alimentary tract of rat, 865.
- in milk, utilization by adults, 416, 417.
- in normal animal at given age, 861.
- in serum, photoelectric microdetermination, 439.
- increase in growing body, effect of nutritional condition, 862.
- lactate solutions in intestine, changes in composition, 862.
- requirement of man, 417.
- requirements of pigs, Tex. 226.

*Callosobruchus maculatus*, see Cowpea weevil.  
*Calomysiterus setarius*, notes, Conn.[New Haven] 65.

*Calosota metallica* parasite of wheat joint-worm, U.S.D.A. 514.

## Calf(ves)—

- achondroplasia in, 177.

## Calf (ves)—Continued.

- beef, rate of gain during suckling period, 228.
- creep feeding, Ga. 816.
- dairy, yeast in concentrate mixtures for, 671.
- dry-fed systems for raising, comparison, N.H. 374.
- fattening, dehydrated sweetpotatoes v. shelled corn for, Tex. 226.
- fattening ration, optimum amount of cottonseed cake in, Miss. 78.
- feeder, grades on Mississippi rations, Miss. 572.
- feeder, mercury poisoning in, 250.
- finishing, Delta-grown oats and barley v. corn for, Miss. 78.
- finishing, dried sweetpotatoes for, Miss. 78.
- infection with *Bacterium enteritidis dublin*, 250.
- internal parasites, control and elimination, 250.
- lousy, sulfur feeding to, Tex. 214.
- milk substitute v. skim milk for, Tex. 233.
- scours, control by feeding adequate vitamins A and B, Wis. 820.
- scours control, effect of vitamin therapy, 521.
- scours, studies, 682, Mich. 682.
- vaccination, United States experimental project, 531.
- vitamin A requirements, Wis. 820.
- wintering, Nebr. 76.
- wintering, alfalfa v. soybean and Korean lespedeza hays for, U.S.D.A. 665.

*Camellia japonica*, varieties, fertilizers, transplanting, pests, etc., Miss. 485.

Camellias, fumigation with methyl bromide, Ala. 651.

Camels, spermatogenesis in, chromosome behavior during, 610.

*Camnula pellucida*, see Grasshopper, clear-winged.

Canalgre for tannin, Tex. 180.

## Cane borer—

- bronze, biology and control on brambles, 71.
- red-necked, biology and control on brambles, 71.

Cankerworms, spring and fall, control with concentrated spray applied with autogiro, 358.

*Canna indica* mosaic, experimental transmission of, 357.

Canned fruit and vegetable labeling, abc grades, U.S.D.A. 270.

Cannery crops, acreages, production, price, etc., Del. 256.

Cannibalism in White Leghorn pullets in laying house, 517.

Cantaloup, see Muskmelon(s).

*Capitophorus braggii* on artichoke, Calif. 507.

## Carabao—

- raised for milk, selection, feeding, and management, 83.

## Carabao—Continued.

role in meat packing industry in Philippines, 228.

## Carbohydrate—

- characterization, 435.
- formation in leaves, effect of omission of red and blue-violet rays from electric light, 454.
- metabolism, 123, 413.

## Carbon(s)—

- activated, from agricultural wastes, 738.
- bisulfide vapor as insecticide, effect on germination of rice, 508.
- dioxide requirement of bacteria, 761.
- dioxide utilization by heterotrophic bacteria, 761.
- dioxide utilization, radioactive carbon as indicator, 170.
- in soils, determination, 731.

## Carnation(s)—

- breeding, N.C. 42.
- Fusarium* wilt, effect of soil temperature, 636.
- nutritional requirements, Colo. 623.
- root rot resistance, Colo. 636.

## Carotene—

- absorption and retention by hens on low-fat ration, 231.
- adsorptive power of magnesia for, Tex. 151.
- and human requirements, 865.
- commercial, purity and stability, 151.
- destruction by certain feeds, 817.
- destroying power of feeding stuffs, 518.
- determination, simplification of method, 10.
- extraction from plant material, 586.
- formation in leaves, factors affecting, 450.
- in grassland herbage, 514.
- in milk, 237.
- pure, in green vegetables and feeding stuffs, 441.
- stability in dehydrated sweetpotato, S.C. 14.
- utilization, effect of fats and unsaturated fatty acids, 422.
- vitamin A synthesis from in rat, 561.

## Carotenoid(s)—

- physical and photochemical properties, 606.
- pigments of corn grain and leaves, Ind. 6.
- silage, in butterfat, 237.

Carpet grass pastures, production, effects of fertilizers, Tex. 181.

*Carpocapsa pomonella*, see Codling moth.

## Carrot(s)—

- improvement by selection, Nebr. 42.
- market diseases of, U.S.D.A. 796.
- molds in markets, 639.
- rust fly, studies, Wash. 811.
- varietal differences in composition, 190.

Carson River, forecasting date of decline on basis of contributing snow cover, 444.

## Cartodere—

- filiformis*, life history, 809.

*Cardiaca*—Continued.

*flum*, life history, 809.

## Casein—

hydrolyzate, preparation, 859.  
lactic, foaming, causes and prevention, 87.

## Cassava—

bacteriosis control, 55, 205.  
Brazil No. 1, description, P.R.U. 182.  
dieback, P.R.U. 51.  
diseases in Jamaica, 789.  
fertilizer tests, P.R.U. 34, 318.  
nutritive value, 855.  
polyploid, induced by colchicine treatment, 27.  
roots, analyses of varieties, P.R.U. 292.  
variety tests, P.R.U. 34.

*Cassia occidentalis*, growth-promoting and inhibiting substances from stem and root, distribution, 602.

## Castor-bean(s)—

tests, Miss. 467.  
tick, life cycle, 815.  
varieties, oil-yield tests, P.R.U. 6.  
variety tests, Nebr. 33, Tex. 180.

Cattle—*see also* Calf(ves), Cow(s), Heifers, Livestock, and Steers.

baby beef, classification in Mississippi, 225.

## beef—

cooperative research, 225.  
letter of unusual interest on, 143.  
records of performance for, 662.  
reeds as grazing crop for, N.C. 77.  
vitamin A requirements, Tex. 225.  
wintering, cottonseed meal as grass hay supplement for, N.C. 77.  
wintering in southeast, 225.  
wintering, rations for, Ga. 816.  
biting-louse, biology, 808.  
blindness due to papilledema, 521.  
blood content, relation to productivity, 610.

dairy—*see also* Cow(s).

breeding records of one large herd, 671.  
cobalt deficiency disease in, Mich. 91.  
grazing for, annual crops v. permanent pastures, U.S.D.A. 820.  
legume silage for, Pa. 81.  
physiology of, 669.  
reproduction in, Oreg. 83.  
selection, feeding, and management, 820.  
vitamin A intake relation to concentration of plasma ascorbic acid and breeding efficiency, Wis. 820.  
vitamin A requirements, Ind. 80, Tex. 233.  
falling disease, in Western Australia, 247.  
farms, organization and management, Va. 694.  
fattening—  
citrus products for, Tex. 225.

## Cattle—Continued.

fattening—continued.

grain sorghums v. corn for, Nebr. 76.  
hybrid v. open-pollinated corn for, Nebr. 76.  
on roughage alone, N.C. 77.  
soybean meals v. cottonseed cake as protein supplements, Nebr. 76.

## feeding—

and management, Ga.Coastal Plain 225.  
emphasis on vitamins in, Mich. 669.  
experiments, Fla. 227.  
experiments, double change-over design for, 668.  
vitamin A-rich feeds as supplements to cottonseed meal in, N.C. 80.  
feed-lot costs for in irrigated districts, Colo. 691.

gastrointestinal tracts, pH value of contents, 663.

gastrointestinal parasites in, Tex. 243.  
grading demonstrations in Mississippi, 225.

grub larvicides, comparison of preparations of rotenone, derris, and cube, 388.  
Holstein-Friesian, herd improvement with sires of superior pedigrees, Del. 374.

horns, preventing growth, Miss. 572.

internal worm parasites, 242.

lice of Great Britain, 808.

louse, short-nosed, biology, 808.

manure, conservation, Vt. 296.

metabolism studies, N.H. 225.

Middle Park hay and North Park hay for, Colo. 662.

nutrition of, 816.

on range vegetation, effect of intensity of grazing, U.S.D.A. 662.

parasites, P.R.U. 87, 382.

parasites of Puerto Rico, 383.

pasture comparisons with, Miss. 816.

plague, *see* Rinderpest.

poisoning, *see* Livestock poisoning, Plants, poisonous, and specific plants.

range, seasonal calcium and phosphorus requirements, N.Mex. 77.

retained placenta in, cause and treatment, 387.

serum phosphatase of, 821.

spray testing, 388.

testing with johnin, 680.

ticks, *see* Tick(s).

ultraviolet irradiation of, effect, 842.

vitamin deficiencies, 242.

Zebu cross, possibilities in North Australia, 460.

## Cauliflower—

fertilizer tests, Miss. 776.

production, starter solutions in, 624.

variety tests, Miss. 776.

Cecidomyiid flies from phlox, two new species, 512.

Cedar, white, posts, preserving, Conn.[New Haven] 49.

## Celery—

- blackheart development, factors affecting, 490.
- early blight in Everglades, spraying and dusting for, Fla. 797.
- market diseases of, U.S.D.A. 796.
- mosaic, western, studies, U.S.D.A. 336.
- plant, spontaneous triploid, 608.
- ratio of petiole to entire leaf length, charts for computation, 41.

Cell(s)—*See also* Plant cell(s)

- resting, respiratory activity, measures of, 21.

## Cellulose—

- acetate fabrics, effect of light and heat on breaking strength, color, and copper number, 138.
- bacteria, aerobic mesophilic, separation, 309.
- cuprammonium fluidity, role of velocity gradient in determining, 733.
- decomposing and N-fixing bacteria, cooperation between, 762.
- decomposition by saprophytic chytrids, 761.

*Celtis*, American species, anatomy of secondary xylem, 760.

## Census, 1940, highlights of, 400.

*Cephalosporium balanoides* n.sp., notes, 62.*Cephenomyia* in Virginia deer, 383.*Cephus pygmaeus*, *see* Sawfly, European wheat stem.*Ceratitis capitata*, *see* Fruitfly, Mediterranean.*Ceratostomella*—

- radicicola* n.sp. on date palm, 502.
- radicicola*, relation to rhizosis of date palm, 349.
- ulmi* in elm wood, 72.
- ulmi* spores, artificially feeding to elm bark beetle and elm borer, technic for, 639.
- ulmi*, transmission by *Scolytus multistriatus*, 71.

*Cercospora*—

- aleuritidis* causing leaf spot of tung oil trees, 61.
- beticola* control on beets, spraying methods, 493.
- brachypus* leaf disease, U.S.D.A. 789.
- brown spot of sugarcane, 496.
- henningii* and *C. caribaea* on manihot, 494.
- lathyrina*, cause of pea leaf spot, 346.
- leaf spot on chrysanthemums in Alabama, U.S.D.A. 636.
- leaf spots on peanut, control, 489.
- leucothoes* n.sp., description, 491.
- medicaginis* on *Medicago arabica*, 490.
- new species, 789.
- personata* notes, 56.

*Cercospora* foot rot of wheat, 788.Cereal(s)—*see also* Grain(s) and specific grains.

- American, vitamin B<sub>1</sub> in, 708.

## Cereal(s)—Continued.

- and grasses, intergeneric hybridization, 763.
  - and rickets, 125.
  - behavior of selenium compounds in, 727.
  - chemical studies, U.S.D.A. 723.
  - crops protection with sulfur dusts, 489.
  - digestibility by minks, 351.
  - diseases, control, 492.
  - diseases in Philippines, 337.
  - diseases in Virginia, U.S.D.A. 636.
  - diseases, virus, diagnosis, 492.
  - for poultry, antirachitogenic nature, U.S.D.A. 662.
  - germination and growth, effect of phytohormones, 622.
  - grass, dried, effect on hatchability and egg production, 517.
  - growing in pots, support for, 181.
  - hardening against atmospheric drought, 163.
  - in heading stage, frost injury to, 469.
  - laboratory methods with reference tables, 441.
  - plants, conduction of water through stem, method of study, 306.
  - rust(s)—*see also* Rust(s) and specific hosts.
    - in Great Plains region, U.S.D.A. 636.
    - in South India, *Darluka flum* on, 342.
    - studies, 637.
  - seed treatment, *see* Seed treatment.
  - smut, *see* Smut and specific hosts.
  - vitamin B<sub>1</sub> stability, effect of long cooking, 132.
- Cerotelium desmum* on cotton in Argentina, 641.
- Cervicitis of pregnant mares, diagnostic value of stamp-smear method, 677.
- Cestodes, anoplocephaline, of hares and rabbits, life history studies, 244.
- Cevitamic acid, *see* Ascorbic acid.
- Chaconmelas lagenaria*, limitations as horticultural plant, 783.
- Chaetomium funicola*, dissimilation of glucose by, 727.
- Chalaropsis thielarioides*—
- cause of rose bud union failure, 200.
  - notes, 802.
- Chalcid flies, revision of genus *Monodontomerus*, 661.
- Chalcis*-fly infested clover and alfalfa seed, problems in analysis, 622.
- Chalcodermus deneus*, *see* Cowpea curculio.
- Chalcoela iphitalis*, life history notes, 813.
- Changa, specific parasite of, establishment in Puerto Rico, P.R.U. 66.
- Charcoal—
- kiln, portable, using chimney principle, Conn.[New Haven] 394.
  - production, better methods, Conn.[New Haven] 49.
- Chard seed pregermination chilling treatment, effect on germination, Conn.[New Haven] 32.

## Cheese—

- aged, identification of white particles appearing on, N.Y.State 520.
- bacteriology, Iowa 380.
- blue, ripening, relation to lipolytic and proteolytic activities of *Penicillium* spp., 377.
- brick, bacteriology, growth and activity of starter bacteria, 826.
- brick, delayed salting, 381.
- brick, ripening, role of surface microflora in, Wis. 820.
- brick, salting, optimum time for, Wis. 820.

## Cheddar—

- composition, 825.
- making, control of acid development in, 381.
- properties, effects of varying pitching consistency and rate of scald, 675.
- quality, factors affecting, 241.
- ripened, gas production and oxygen consumption in, N.Y.State 520.
- ripening, relation to fat hydrolysis, Iowa 380.
- southern short-cure, quality, effect of various temperatures, Tex. 233.

## Gouda, manufacture, 241.

## Italian, varieties, 826.

## Limburger, of New York State, improvement, 826.

- making, bacteriophage in, 525.
- making, new method, 826.
- methods of packaging, Wis. 820.
- molds and bacteriophage, irradiation by ultraviolet light, 86.
- new variety, Husker, Nebr. 80.
- ripening studies, 525.
- soft, varieties, 241.
- surface-ripened, bacterial control in, N.Y.State 520.
- Swiss, quality, relation to fat and standardization of fat content, 86.
- types, flavor development in by microorganisms, 673.
- volatile acids of, 675.
- whey, vitamin B<sub>2</sub> concentrate from, U.S.D.A. 819.

*Cheilosia baroni* on artichoke, Calif. 507.Chemistry, colloid, *see* Colloid chemistry.

## Cherry(ies)—

- black, longevity in Pennsylvania, 635.
- buckskin disease, 210.
- carbon dioxide treatment in transit and storage, 47.
- fruitfly—
  - biological studies, 361.
  - black, studies, N.Y.State 652.
  - control, 352.
  - studies, N.Y.State 652.
  - toxicological studies, 361.
- leaf spot, control, N.Y.State 490.
- leaf spot on nursery trees, control, Ind. 51.

## Cherry(ies)—Continued.

- maraschino, improved in flavor, N.Y. State 270.
- Montmorency, mahaleb v. mazzard stocks for, N.Y.State 477.
- of U. S. No. 1 grade and slightly smaller fruits, relative juice yield from, Colo. 700.
- polyploidy in, induction, 42.
- sour, fertilization and mulching, Colo. 623.
- sour, spraying, interstate cooperative experiments, 348.
- variety tests, Ga. 776.
- yellow, severity in New York, 799.

## Chestnut—

- blight, induced immunity to, 503.
- blight studies, U.S.D.A. 336.
- breeding in 1940, 803.
- diseases and other disturbances, 802.
- posts, preserving, Conn.[New Haven] 49.
- trees and nuts, diseases of, 503.

## Chick(s)

- antirachitic value of lamp radiation for, Nebr. 76.
- autosexing Ancobar, development, 314.
- battery brooded, minerals in rations, 517.
- bone marrow, blood cells in, before and after hatching, 230.
- brooding, infrared lamps for, Nebr. 98.
- brooding, use of electricity in, Ind. 97.
- choline in nutrition of, 231.
- creeper factor in, early lethal action, 707.
- crude fiber for, Tex. 226.
- day-old, gizzard lesions in, 517.
- effect of heat on growth-promoting value of specific ration, 518.
- effect of sulfur on, 253.
- effects of sulfur feeding, 372.

## embryo(s)—

- antigenicity, 245.
- development, effect of increased pantothenic acid in egg, 371.
- 11-day, chloride in blood, 518.
- individual, respiratory behavior, 518.
- infection with *Bacterium tularense*, *Bruceella*, and *Pasteurella pestis*, 384.
- mortality, effect of formaldehyde fumigation, Ky. 95.
- response of gonads to gonadogen, 179.
- experimental infection with *Hexamita meleagridis*, 538.
- flavin requirements, Ind. 76.
- gizzard erosion and cholic acid in, effect of milk on, 231.
- gizzard erosion in, 231.
- growing, hybrid v. open-pollinated corn for, Nebr. 76.
- growth and mortality, effect of colored light and colored walls, 370.
- growth, effect of electric lights and ultraviolet irradiation on, Ind. 76.
- growth, effect of green feeds, 518.

## Chick(s)—Continued.

- growth, retardation by sulfur, Tex. 226.  
 hereditary microphthalmia in, 314.  
 infected with *Eimeria tenella*, treatment with vitamin K, 684.  
 iodine requirements, 518.  
 meat scraps and soybean meal for, lower levels after starting, Ind. 76.  
 methionine in diet, 231.  
 new growth factors for, evidences, 517.  
 nutrition, choline in, 517.  
 nutrition, effect of growth factor required by *Lactobacillus casei*, 667.  
 nutrition, inositol in, 231.  
 pigment deposition in, effect of protein supplements in inhibiting, 230.  
 polydactyl feet of two strains, 767.  
 proliferation and hydration of combs and cloacae, effect of sex hormones, 769.  
 rations, mineral partition during intestinal digestion, 667.  
 rice factor for, carbohydrate component, 230.  
 sexing, and modifiers of sex-linked gene for barred feathers, 765.  
 sexing by sex-linked characters, 614.  
 shank and skin color in, 230.  
 6 week-old, protein levels, Ind. 76.  
 slipped tendon in, see Perosis.  
 slow feathering in, recessive autosomal factor for, 461.  
 tryptophan requirement, 666.  
 2-week-old pullet, effect of unabsorbed yolks in, 517.  
 urea nitrogen utilization by, 666.  
 utilization of cereal grains and time of consumption by, Nebr. 76.  
 vitamin A and D requirements, sources of protein for, Tex. 226.  
 vitamin A storage in liver, relation to intake, Tex. 226.
- Chicken(s)—see also Chick(s), Cockerels, Fowl(s), Hen(s), Poultry, and Pullet(s).  
 broiler, dried milk and condensed whey in ration, Ind. 76.  
 broiler production and marketing, Ark. 108.  
 dressed, post-mortem changes in New York at 35° F., 391.  
 feathering at broiler age, relation to day-old chick wing feather development, 461.  
 preserving by quick freezing at home, N.Y.State 268.
- Chicken pox, successful vaccination against, 96.
- Chicory, levulose from, 737.
- Chigger control in Missouri, Mo. 662.
- Children—see also Boys, Girls, and Infant(s).  
 co-carboxylase, pyruvic acid, and bisulfite-binding substances in, 860.  
 effect of tea on energy metabolism, Tex. 267.  
 feeding, 555.  
 growth in, clinical appraisal, 858.

## Children—Continued.

- institutional, ascorbic acid in blood plasma of, 870.  
 measure of metabolic speed in, 857.  
 physical measurement, 857.  
 preschool, breathing capacity and grip strength, 124.  
 school, in small industrial city, nutritional status, 858.  
 school lunch as supplement to home diet, 858.  
 school, of London, nutrition and dental caries in, 863.  
 white, school, trend of weight in, from 1933 to 1936, 271.  
 with large or small reserves of vitamin C, tests, 136.
- Chimneys and fireplaces, design, construction, cleaning, and repair, U.S.D.A. 844.
- Chinch bug(s)—  
 control, Conn.[New Haven] 65.  
 false, studies, Tex. 214.  
 hairy, control, Conn.[New Haven] 65.  
 in Ohio wheatfields, Ohio 216.  
 studies, Ind. 65, Nebr. 65.
- Chionaspis*—  
*etrusca*, notes, 64.  
*cuonymi*, see Ecuonymous scale.  
*furfura*, see Scurfy scale.
- Chlorate—  
 distribution in soil columns and effect of nitrate concentration on its toxicity, Calif. 297.  
 toxicity, inhibiting effect of nitrate on, 23.
- Chlorella vulgaris*, dry weight, factors affecting, 171.
- Chloride nutrition for plants, significance, 757.  
 $\beta$ -2-chloroethyl- $\alpha$ -glucoside, synthesis by wheat plants grown in special medium, 167.
- Chlorohexylmetacresol, low toxicity for mammals, 245.
- Chlorophyll(s)—  
 determination, simplification of method, 10.  
 physical and photochemical properties, 606.  
 spectroscopy of, Ind. 6.  
 Chlorophyllase activity, variation in plants, 436.
- Chlorosis—  
 in perennial pepper, 495.  
 in roses, lime and acid induced, 490.  
 in stone fruits, control, Colo. 636.  
 in vegetable and feed crops, Tex. 202.  
 iron, in shelterbelt trees, 803.
- Chlorotic streak, results of experiments with, 795.
- Chocolate coating(s)—  
 for ice cream, viscosity and coverage value, 382.  
 studies, 242.
- Chokecherry "X" disease in Michigan, U.S.D.A. 50.
- Cholestenes,  $\Delta^8$ ,  $\Delta^8$  ( $^{14}$ ), and  $\Delta^{14}$ , preparation, 580.

## Choline—

- deficiency in young rats, Ala. 700.
- deficiency in young rats, improved diets for study, 420.
- metabolism, studies, 274, 275, 850.

*Chondrococcus blasticus* n.sp., description, 761.

*Chorcutis melanifera* on artichoke, Calif., 507.

*Chorthippus longicornis*, genetic studies, 767.

*Christisonia wrightii* parasitizing sugarcane, 57.

## Chromosome(s)—

- behavior during spermatogenesis in camels, 610.
- changing number for better cotton, N.C. 34.
- chemistry of, 25.
- doubling, production by chemicals, 638.
- doubling, experimentally induced in *Solanum tuberosum* and related species, 450.
- new stain-fixative for, 455.
- number in beach plum, 27.
- numbers of *Vaccinium* spp., 27.
- of ducks, pheasants, and pigeons, morphology, 614.
- structure, photographic determination, N.Y.State 454.

## Chrysanthemum(s)—

*Cercospora* leaf spot in Alabama, U.S.D.A. 636.

leaf nematode control, Conn.[New Haven] 51.

resistant to *Verticillium* wilt, 801.

*Chrysomphalus aurantii*, see Red scale, California.

Church and land tenure, 266.

*Chyphotes* genus of North America, monograph, 812.

*Chytridiaceae*, cellulose decomposition by, 761.

Cider, letter of unusual interest on, 143.

Cigars, experiments on burn of, Wis. 437.

## Cigarette beetle—

- excluding from warehouses, type of wire screen required, 352.
- larvae fumigated with hydrocyanic acid, revival, 363.

*Cimex lectularius*, see Bedbug.

## Cinchona cultivation—

- and production of totaquina in Philippine pines, 784.

in India, prospects, 196.

Cinerarias, growth on Iowa soils, 196.

*Cintractia sorghii*, cause of Sudan grass smut, 496.

*Cirphis unipuncta*, see Armyworm.

*Oitellus harrisii*, animal reservoirs of, 828.

Citizen and power to govern, Iowa 264.

## Citric acid—

- absorption and fate in rat, 861.
- metabolism, by infants, 274.

## Citrus—

- adventitious buds in, 485.
- bud mite, life history, habits, and control, 661.
- chlorosis and gummosis, Tex. 202.

## Citrus—Continued.

chromosome determinations, Tex. 180.

cuttings and budlings, initial and subsequent size, 485.

effect of phosphorus deficiency, Calif. 800.

effect of sulfur deficiency, Calif. 800.

foot rot in Brazil, control, 800.

fruit(s)—see also Lemon, Orange(s), etc.

breeding, Tex. 180.

brown rot in Argentina, cause, 501.

dried, for marmalade, 702.

molds in markets, 630.

Texas, problems in estimating, 400.

in South America, *Phytophthora* spp. on, 60.

industry, benefit from refrigeration research, U.S.D.A. 843.

orchards, irrigations in, timing, U.S.D.A. 776.

leaves and fruits, absorption and retention of hydrocyanic acid by, 656.

leprosis control, 648.

manganese deficiency in, 485, 501.

melanose control, review, 211.

mite, Texas, population studies, Tex. 214.

nutrient deficiencies and excesses in, symptoms, 200.

peel, dried, and pulp for fattening cattle, Tex. 225.

pests, studies, 216.

plants, frost resistance, effect of day length, 308.

plants, frost resistance, effect of mineral nutrition, 163.

propagation, P.R.U. 42, 326.

root rot in Corrientes, Argentina, 648.

rootstock tests in southern Nigeria, 485.

rust mite, population studies, Tex. 214.

thrips control, 217.

tissue, resistance to heat, 200.

trees, nutrient requirements, U.S.D.A. 776.

trees, resistance to freeze damage, relation to grove practices, 333.

under shipment, refrigeration, U.S.D.A. 776.

verrucosis, 648.

wood, lignin content, 163.

Civil-service employment in U. S. Department of Agriculture, U.S.D.A. 143.

*Cladosporium fulvum* notes, U.S.D.A. 788.

Clays of Iowa for clarification of sorgho juice, 736.

Cleaning agents, germicidal action, modification of Price's procedure, 87.

Climate—see also Meteorology.

and man, yearbook of agriculture, U.S.D.A. 293.

and tree rings, 591.

and weather data for United States, U.S.D.A. 294.

and world pattern, U.S.D.A. 293.

limiting factor in South Dakota agriculture, U.S.D.A. 294.

## Climate—Continued.

- of Maryland and Delaware, useful data on, 740.
- of south Chinese-Tibetan borderland, 295.
- of the world, U.S.D.A. 294.
- uniform, of Malaya as barrier to plant migration, 591.

## Climatic—

- change through the ages, U.S.D.A. 293.
- conditions in Dominican Republic, 591.
- cycles, relation to theory and practice of conservation, 446.
- types in United States, atlas of, U.S.D.A. 590.

## Climatological data, 156, 295.

## Climatology, physical, 294.

*Clostridium* spp., CO<sub>2</sub> requirement, 761.

## Clothes moth, webbing, parasite of, 812.

## Clothing—

- and pattern construction, women's measurements for, U.S.D.A. 874.
- cotton corduroy, for boys, properties, 715.
- family expenditures for by farm families, U.S.D.A. 141.
- for school-age boys, girls, Miss. 571.
- importance, in air conditioning, 874.
- making and buying, U.S.D.A. 714.
- work, for women, U.S.D.A. 714.

## Clove disinfection, Tex. 202.

## Clover(s)—

- alsike, separation of immature seeds, 622.
- and timothy hay, fertilizer tests, N.H. 317.
- boron for, field trials with, 341.
- crimson, v. hairy vetch as soil-conserving crop, Ala. 593.
- establishment and survival on native pasture, Tex. 181.
- from Arizona and New Mexico, reclassification, 20.
- Ladino, experiments, [Conn.] Storrs 319.
- leafhopper, control, [N.Y.] Cornell 217.
- mites, Conn. [New Haven] 65.
- new immigrant to North America, 600.
- red—
  - adapted and unadapted, yields, effect of planting rate, 320.
  - and white, improvement, N.H. 318.
  - breeding, U.S.D.A. 771.
  - hay, high-phosphorus v. low-phosphorus for calves, 225.
  - new strains, U.S.D.A. 774.
  - seed, *Chalcid*-fly infested, method for purity analysis, 622.
  - self-fertility in, 175.
- seed, harvesting with grain threshers and combines, Wis. 774.
- variety tests, Tex. 180.
- white—
  - breeding, U.S.D.A. 771.
  - cystine and methionine in, 664.
  - elimination from Alabama pastures during summer, cause, Ala. 636.
  - failure in South, role of diseases in, 489.

## Clover(s)—Continued.

## white—continued.

- growth, effect of potassium concentrations and volume rate of solution supply, 300.
- seed germination, factors affecting, 36.
- self-incompatible plants, cross-incompatibility among, genetics of, 26.
- separation of immature seeds, 622.
- strain differences in germination and effects of scarification, Ala. 616.
- superiority of wild or permanent pasture types, N.Y. State 623.

## Cont making at home, U.S.D.A. 875.

## Cobalt—

- deficiency disease in dairy cattle, 247, Mich. 91.
- deficiency on limestone soil, 599.
- traces of, colorimetric determination, 584.

## Cobra venom and vitamin C, 279.

## Coccarboxylase—

- activation by thiamin, 710.
- in blood of children, 860.

## Coccidae, coconut-feeding, control, 510.

## Coccidia—

- in sheep at the Utah State Agricultural College, 831.
- intestinal, of rabbits, life cycles, 828.
- Coccidial oocysts and helminth eggs, simultaneous flotation, zinc sulfate v. sugar solutions for, 356.
- Coccidioides, isolation from soil and rodents, 828.
- Coccidioidomycosis, cause, and its fungus parasites, 828.

## Coccidiosis—

- control, steamed bonemeal and organic sulfur compound tests, Wis. 827.
- experimental bovine, effects of sulfaguanidine on, 827.
- immunization against by X-ray attenuated oocysts, 827.
- in chickens, immunization by X-ray-attenuated oocysts, 536.
- in chickens, sulfaguanidine feeding for control, 827.
- in lambs, control, Colo. 676, U.S.D.A. 676.
- vaccination of chicks for, Wis. 827.

*Coccomyces* leaf spot of cherry, control, N.Y. State 490.*Cochlonema symplocum* n.sp., description, 491.

## Cockerels—

- effect of sunlight, dubbing, and fractionated anterior pituitary extract, 461.
- of two breeds, development of testes and combs, 768.

## Cockroach—

## American—

- effect of infrared irradiation, 352.
- relative efficiency of insecticide dusts against, 808.
- role in dissemination of brucellosis, 527.

- Cockroach—Continued.  
 American—Continued.  
   toxicity of pyrethrins I and II in kerosene to, U.S.D.A. 806.  
 German, embryogeny, life history, and importance, 213.  
 German, relative efficiency of insecticide dusts against, 808.
- Cocoa—  
   effect on digestibility of milk proteins, 122.  
   insects in Malaya, 216.  
   natural pollination on Gold Coast, 784.
- Coconut(s)—  
   average yield and cost of production, P.R.U. 104.  
   cadang-cadang and associated fungi in Philippines, 337.  
   diseases in Jamaica, 789.

   in South, cultural-agricultural islands, reconnaissance, 265.

## Community (ies)—Continued.

land-use planning committees, organization, leadership, and attitudes, Ky. 852.

rural, building, papers on, 697.

stability and instability in El Cerrito, N. Mex., U.S.D.A. 697.

*Comperiella*—

*bijasciata*, successful propagation in California, 223.

introduction into California from China by air transport, 223.

## Concrete—

sawdust, test results, 838.

wallows for pigs, Tex. 226.

## Condensation-nuclei, errors in measurements, 444.

## Coneflowers of North Dakota, N.Dak. 430

## Conifer(s)—

fall sowing of seed, N.Y.State 198.

in Rhine Valley, Mycorrhizae of, 600.

mixed plantation, growth and development, 198.

needles and their water extracts as carriers of vitamin C, 428.

of northern Ontario, root systems on sand plain, 198.

seed crops of basis for forecasting, 486.

seed germination, N.Y.State 477.

wind scorch, Conn.[New Haven] 51.

*Coninomus nodifer*, life history, 809.

## Connecticut [New Haven] Station—

notes, 144.

report, 143.

*Conopia scitula* on top-worked pecan trees, control, 70.*Conotrachelus* weevils of South America, 810.

## Consumer education—

in the schools, textbook, 120.

materials for, U.S.D.A. 267.

## Consumption, a vast underdeveloped economic frontier, 399.

*Contarinia* spp., notes, 221.

## Cookies—

quick frozen, 552.

vitamin-rich, recipes, Mich. 709.

## Cooking utensils, studies, U.S.D.A. 716.

Cooperation—*see also* Agricultural cooperation.

laws pertaining to in United States and possessions, abstracts, 545.

laws pertaining to, index, 544.

legal phases of, 545.

Cooperative marketing, *see* Marketing

## Cooperative purchasing association, membership relations, 110.

*Cooperia*—

*curticei*, spicule length as measure of favorable intestinal environment in sheep, 365.

*pedunculata*, alkaloids and toxicity to *Phymatotrichum omnivorum*, 793.

## Coof, American, food habits and distribution, 212.

## Copper—

colorimetric determination with ammonia, 730.

## Copper—Continued.

deficiency disease of cattle, 247.

deposition on cucumber leaves, effect of aluminum on, 200.

effect on yields of peanuts, N.C. 34.

fungicides, fixed, tests, Ga.Coastal Plain, 201.

in biological material, microdetermination, 439.

in fertilizers, spectrochemical analysis, 732.

in serum, rise after administration of copper sulfate, 706.

radioactive, and mechanism of oligodynamic action, 638.

sulfate-nicotine sulfate mixture v. phenothiazine as anthelmintics for sheep, 251.

sulfates used as fungicides, hydroxide in, determination, 733.

*Coprinus*—

*micaccus* in an unusual habitat, 790.

sp., cultural characteristics, 790.

## Corduroy, cotton, for boys' clothing, properties, 715.

## Corn—

and legumes, interplanting, Miss. 773.

and small grains, comparative yields, Ga. 772.

autotetraploid, inbred and open-pollinated strains, chromosome studies relation to fertility and vigor in, 450.

bacterial wilt, 788.

bibliography, 1917 to 1936, Iowa 183.

## borer, European—

comparative injury to open-pollinated and hybrid field corn, 358.

control, 507, Conn.[New Haven] 64, 65, N.C. 65.

control by dusting early corn, 380.

in Galicia, 352.

kill secured with corn husker shredder, Ind. 97.

moths, factors governing flight to electric traps, 359.

possible control by electric traps, Ind. 65.

use of dusts for, N.Y.State 652.

borers in Galicia, studies, 352.

breeding, Colo. 616, Conn.[New Haven] 32, Ga.Coastal Plain 179, Ind. 32, N.C. 34, Nehr. 33, P.R.U. 34, Tex. 180, U.S.D.A. 771.

breeding program, use of Corn Belt inbreds in, 317.

canning wastes, lagooned, biological treatment, 309.

charcoal rot, U.S.D.A. 788.

chromosomes in, stability of broken ends of, 173.

cockle feeding to chickens, 517.

coleoptile, protoplasmic growth and nitrogen migration in, 22.

combining, progress in, 838.

crossing over in male and female gametes, different rates, 172.

## Corn—Continued.

- culture experiments, Ga.Coastal Plain 179, Miss. 772, Tex. 180.
- cutting, low, demonstrations, Ind. 97.
- dent, inbred P<sub>1</sub> to infection by *Helminthosporium maydis*, race 1, inheritance of susceptibility, Ind. 51.
- distillers' dried grains with solubles in poultry rations, 371.
- double crosses, predicting performance, use of punched card equipment, 36.
- ear rots, incidence in 1940, U.S.D.A. 336.
- earworm—
  - control on sweet corn, 220.
  - control, status of mineral oil treatment for, N.Y.State 651.
  - hibernation, U.S.D.A. 359.
  - on artichoke, Calif. 507.
  - on flax, studies, Tex. 214.
  - on lima beans, control, U.S.D.A. 806.
  - resistance and plant characters, 191.
  - studies, Ind. 65, Tex. 214.
- equipment for cultivating, 395.
- Euchlaena*, and *Tripsacum*, genetic and cytological relations, Tex. 180.
- F<sub>1</sub> and F<sub>2</sub> lines, yield prepotency, lodging, and disease resistance in, segregation of genes affecting, 172.
- fertilizer formulas and rates of application, Ga.Coastal Plain 179.
- fertilizer tests, Ga. 772, Ind. 32, Miss. 772, N.C. 34, P.R.U. 318, Tex. 180.
- grain and leaves, carotenoid pigments, Ind. 6.
- grain yield and total dry matter, correlation, 470.
- ground shelled, v. dehydrated sweetpotato meal for lactating cows, Tex. 233.
- growing point, periclinal division in dermatogen at tip, 21.
- growth, effect of climate and weather, U.S.D.A. 294.
- heat and drought tolerance in, genetic studies, 25.
- Helminthosporium* blight, U.S.D.A. 201.
- heritable characters in, knotted leaf, 456.
- husker shredder, power requirements and corn borer kill secured with, Ind. 97.
- hybrid(s)—
  - merits of different combinations of same four inbreds for, Ind. 32.
  - nitrogen determinations on, Ind. 6.
  - seed increase and registration for, Minnesota method, 36.
  - size-and-shape of seed grades, comparison, Nebr. 33.
  - studies, P.R.U. 318.
  - v. open-pollinated for fattening cattle and growing chickens, Nebr. 76.
- in defense, P.R.U. 287.
- in rotation, sweetclover as intercrop, Ind. 32.
- in Venezuela, distribution of botanical varieties, 601.

## Corn—Continued.

- inbred and hybrid, stomatal behavior in, 173.
- inbred lines, causes of preferences exhibited by animals for, 227.
- inheritance of susceptibility to infection by *Helminthosporium maydis*, race 1, 310.
- inheritance studies with, Tex. 180.
- irrigation tests, Tex. 180.
- Minihybrid varieties for Minnesota, Minn. 36.
- mosaic virus, incubation period and longevity in its vector, 809.
- mutants induced by ultraviolet radiation, transmission tests, Iowa 310.
- N sources for side dressing, La. 33.
- oil fatty acids, effect on signs of egg white disease in rats, 864.
- oil, insecticidal efficiency, U.S.D.A. 807.
- open-pollinated v. hybrid, for hogs, Ind. 76.
- plant composition, relation to soil and its treatment, 321.
- plant, variegated, induced by treating pollen with ultraviolet light, Conn. [New Haven] 82.
- pollen abortion in, cytogenic studies, 457.
- pollen extracts, responses of vegetative plant parts to, 165.
- pollen, germination, 306.
- pollination, new method for control, 183.
- proteins, biological value, 226.
- reactions to smut and firing by means of chromosomal translocations, genetic studies, 173.
- response to fallow and other tillage practices, Nebr. 33.
- response to potash, 317.
- response to seed treatments with hormones and mercurials, 622.
- roasting, varieties, Ga.Coastal Plain 183.
- root and stalk growth, effect of root pruning and prevention of fruiting, 320.
- roots, soil-inhabiting fungi attacking, 480.
- rootworm, southern—
  - resistance of corn strains to, 362.
  - studies, Ga. 806.
- rusts, identity and distribution, 56.
- seed beetle, morphology, 809.
- seed, drying studies, Ind. 97.
- seed, grading, relation to planting, 396.
- seed, hybrid vigor and weight of germs in, 762.
- seed, maturity, Ind. 32.
- seed treatments, value, N.Y.State 204.
- shelled, v. sweetpotato meal, U.S.D.A. 662.
- shelled, v. sweetpotatoes for fattening calves, Tex. 226.
- sirup, enzyme converted, use in ice cream, sherbets, and ices, 382.
- sirup solids, effect on frozen dairy products, 525.

## Corn—Continued.

- sirup solids, use in ice cream and ices, 382.
- sirup, use in ice cream manufacture, Wis. 820.
- soil improvement crops for, Miss. 773.
- spacing tests, La. 32.
- storage studies, U.S.D.A. 835.
- supplemented with lysine and tryptophan, biological value, 226.
- sweet, *see* Sweet corn.
- sweeteners in frozen desserts, N.Y. State 270.
- tillers in, effect on development of main stalk, 470.
- translocations involving short arm of chromosome I, 457.
- U. S. Hybrid 13, outstanding in productivity, U.S.D.A. 771.
- v. sorghum, effects on succeeding crops, Tex. 180.
- varieties, forage yields, Tex. 180.
- variety-spacing test, Tex. 180.
- variety tests, Ala. 615, Ga. 772, Ga. Coastal Plain 179, Ind. 32, La. 32, Miss. 467, 772, N.C. 34, N.H. 318, Nebr. 33, Tex. 180.
- variety tests, accuracy of lattice designs, Iowa 320.
- winter cover and green manure crops for, Ga. Coastal Plain 179.
- work of regional research laboratories on, U.S.D.A. 723.
- yellow, v. sunflower seed for turkeys, Nebr. 76.
- yields and income on dry-farm operating units, Colo. 691.
- yields, effect of—
- crop rotations, N.C. 34.
  - crotalaria and sericea plowed under, Ala. 616.
  - cyanamide and potash plowed under with organic refuse, 183.
  - sowing green manure in, Va. 616.
  - vitamin B<sub>1</sub>, 182.
- yields in rotations, Minn. 773.
- Cornell University, notes, 877.
- Cornstalk(s)—
- collecting, equipment, methods, and costs, 841.
  - flour, anaerobic fermentation by thermophiles, effect of metal containers, 737.
- Cornstarch, waxy and ordinary, fractionation, 580.
- Corpus luteum in cats, development and morphology, 465.
- Correlation analysis, methods, treatise, 876.
- Corticaia fulva*, life history, 809.
- Corticium fuciforme*, pathogenicity and control, R.I. 53.
- Corynebacterium equi*—
- classification, Ky. 87.
  - in submaxillary lymph nodes of swine, 93.
- Coryneum rhododendri fusoides* n. var., 780.
- Coryza, infectious, treatment with sulfathiazole, 536.

## Cosmos—

- effect of growth substances, Ind. 42.
  - tetraploid, colchicine induced and comparisons with diploid progenitors, 312.
- Cotinis nitida*, *see* June beetle, green.

## Cotton—

- added profits from side dressing, Miss. 33.
- after various legumes plowed under at different dates, Ga. 772.
- and climate, U.S.D.A. 294.
- angular leaf spot, studies, Tex. 202.
- angular leaf spot, wind dissemination, 641.
- aphid control, effect on yield, 66.
- aphid, effect of calcium arsenates, 67.
- aphid, effect of cryolite and cryolite-sulfur mixtures for, 67.
- aphid insecticide tests, 68, 653.
- aphid multiplication following treatment with calcium arsenate, 64.
- Asiatic, virescent mutants in, genetical behavior, 458.
- at local markets, quality-price relations, Okla. 695.
- boll characters, immediate effects of pollen on, 471.
- boll rot diseases and associated microorganisms, U.S.D.A. 336.
- breeding, Ala. 615, Ga. 772, Ga. Coastal Plain 179, N.C. 34, P.R.U. 34, Tex. 180, U.S.D.A. 771.
- burs v. manure for cotton, Tex. 180.
- compression and related problems, U.S.D.A. 110.
- cost of production, yield, and net returns, P.R.U. 104.
- crop, size and quality, Miss. 430.
- cultivation, two ideals of, Miss. 33.
- culture experiments, Miss. 467, 772, Tex. 180.
- culture in Congo-Ubangi, 56.
- cytogenetics of, Tex. 180.
- dusting program and soil damage, Miss. 17.
- effect of nitrogenous fertilizers from various sources, Miss. 748.
- experiments, competition effect, size, shape of plat, etc., 450.
- fabric given different treatments and finishes, stiffness of, 283.
- fertilizer(s)—

  - comparisons, Ala. 615.
  - fillers and supplements for, Ga. 741.
  - placement for, Ga. Coastal Plain 179.
  - tests, Ga. 772, La. 32, Miss. 772, N.C. 34, Tex. 180.
  - use of gypsum in, 317.
  - value of sodium in, Ga. 741.

- fiber(s)—

  - length, effects of environment, U.S.D.A. 37.
  - length, effect of internal genetic change, 471.
  - microscopic structure, 138.

## Cotton—Continued.

## fiber(s)—continued.

properties, effect of seedbed preparation and composition of seed, Ala. 615.

research, N.C. 34.

strength of attachment to seed, measurement, U.S.D.A. 617.

structure as revealed by microscope, 607.

## flea hopper—

effect on fruiting of cotton, Miss. 68.

insecticides for, comparison, 66.

studies, Tex. 213.

formulas and carriers in N, P, and K for, Ga.Coastal Plain 179.

fruiting, relation to insects damaging squares, Miss. 68.

*Fusarium* wilt, varietal reaction to, 343, 489.

future, in economy of South, 400.

genetic studies, Ga. 772.

ginning and packing, U.S.D.A. 835.

Ginning Laboratory, United States, work of, U.S.D.A. 539.

ginnings of State, Ga. 845.

gins, converting for use in delinting cottonseed, Ga. 101.

gins, cooperative, expenses, income, and dividends, U.S.D.A. 111.

gins, operating costs and financial conditions, Tex. 256.

growers in Puerto Rico, advice to, P.R.U. 287.

grown at different pH levels, response of, 317.

harvesting and handling practices, U.S.D.A. 471.

hosiery, studies, U.S.D.A. 714.

hybridization, cytology, and polyploidy, 763.

in Arizona, *Sclerotium rolfsii* on, 206.

in defense, P.R.U. 718.

inheritance studies with, Tex. 180.

## insect(s)—

damage, relation to soil conservation practices, 652.

results from airplane dusting in Arizona, U.S.D.A. 806.

studies, Ga.Coastal Plain 210.

survey, studies, Tex. 213.

insecticides, comparison, 66.

irrigation tests, Tex. 180.

leaf worm, insecticide tests, 67.

leaf worm problem in Egypt, 352.

lint, characteristics and interrelations, Tex. 180.

lint, grade of, effect of variety, La. 32.

market, price-quality relations, 401.

marketing, S.C. 406.

marketing, quality-price differentials in, 400.

mechanical harvesting, Tex. 254.

moisture content, relation of oviposition by *Heliothis armigera* and survival of larvae, 660.

N and K carriers for, Tex. 180, 200.

## Cotton—Continued.

N and K top dressings for, Ga.Coastal Plain 179.

nutrition, relation to *Fusarium* wilt, 489.

one-variety communities, increasing and renewing seed stocks in, 622.

pathogens, seed-borne, isolation and infection tests, 489.

Pima, inheritance of smooth and pitted bolls in, 763.

## plant(s)—

growth rate of main stem and yield, 321.

salt resistance, leaf albumins as index, 304.

stunting and crinkling, 641.

plantations, laborers on, La. 119.

potassium studies with, 316.

prematurely killed by cotton root rot, effect of insect control on yield and quality, 489.

rates of potash for, in acid and neutral fertilizers, Ga. 741.

research, U.S.D.A. 772.

research to increase use, 571.

response to potash, 317.

root knot, varietal reaction to, Ga. 788.

## root rot—

control, soil bacteriological studies, 493.

fungus, ammolum salts toxic to, 206.

studies, Tex. 201.

rust due to K deficiency, Ala. 636.

rust in Argentina, 641.

## sea-island—

production, development, Ga.Coastal Plain 179.

production in Florida and Georgia, U.S.D.A. 772.

profits on northeast coast area, P.R.U. 718.

sweetpotato as good succeeding crop, P.R.U. 621.

secondary nutrient elements for, Ga. Coastal Plain 179.

seed, *see also* Cottonseed.

moisture tester for use at gins, U.S.D.A. 690.

## seedling disease—

and boll rot surveys, 489.

in 1941 and associated fungi, U.S.D.A. 50.

probability law in, 342.

soil fertility experiments with, Miss. 33.

soil improvement crops for, Miss. 773.

soils, effect of granulated mixed fertilizers of different particle size, 183.

sources of nitrogen for, Ga. 741.

spacing tests, La. 32.

stem weevil, biology under controlled conditions, 219.

textile industry, Japanese, impact of war on, U.S.D.A. 105.

thrips, studies, Tex. 213.

upland, characteristics, factors affecting, Miss. 310.

## Cotton—Continued.

- upland, inheritance of cluster habit and its linkage relation with anthocyanin pigmentation in, 763.
- value of dolomite on, Miss. 317.
- value of dolomite on brown loam soils, Miss. 33.
- value of Mn and B for, Tex. 180.
- varieties—
  - adapted to mechanical harvesting, development, Tex. 180.
  - new, yields, Miss. 773.
  - standard, new, and improved, Miss. 773.
- variety tests, Ga. 772, Ga.Coastal Plain 179, La. 32, Miss. 487, 772, N.C. 34, P.R.U. 318, Tex. 180.
- variety-wilt-phosphorus study, Ga. 772.
- wilt control, N.C. 51.
- wilt resistance of Shafter Acala variety, 480.
- wilt, varietal reaction to, Ga. 788.
- winter cover and green manure crop, for, Ga.Coastal Plain 179.
- work of regional research laboratories on, U.S.D.A. 723.
- yarns, breaking strength and elongation, 571.
- yields after corn, soybeans, and legumes, La. 33.
- yields after various green manures v. commercial N, Miss. 772.
- yields and fiber length, effect of spacing, Tex. 180.

## Cottonseed—

- and fertilizer, efficiency in distribution and placement, Tex. 255.
- cake, optimum amount for fattening calves, Miss. 78.
- cake v. soybean meals as protein supplements for fattening cattle, Nebr. 76.
- delinting on small experimental cotton gins, Ga. 772.
- disinfection and factors for germinability, 703.
- germination, effect of crude oil and cotton bur ashes on, Tex. 201.
- meal, ad libitum, effect on hatchability of eggs, 225.
- meal as supplement for wintering breeding ewes, Mich. 78.
- meal as supplement to grass hay for wintering beef cattle, N.C. 76.
- meal for pigs, Tex. 226.
- official grading and market news, U.S.D.A. 116.
- oil and ammonia in, effect of fertilization and cultural practices, 155.
- oil, crude, gossypol in, 784.
- oil, hydrogenated, nutritive properties, 702.
- oil, insecticidal efficiency, U.S.D.A. 807.
- planting rate, effect on root rot, Tex. 201.
- protein for plastic molding, Miss. 443.
- treated, effect of storage in closely woven cotton bags, 317.

## Cottonseed—Continued.

- treated with grown substances, root initiation by seedlings, Tex. 180.
- treating with mercury dusts, effect on stands, N.C. 34.
- treatment for planting purposes, Tex. 255.

Cottony-cushion scale, specific predator on, P.R.U. 66.

Country, *see* Rural.

County government in Washington, Wash. 698.

## Cover crops—

- for orchards, Ind. 41.
- relation to nitrogen losses through leaching, Conn.[New Haven] 16.
- winter, culture experiments, Ga.Coastal Plain 179.
- winter, variety tests, Ga.Coastal Plain 179.

Cow(s)—*see also* Cattle and Heifers.

- beef, mineral and vitamin A needs, U.S.D.A. 662.
- blood picture, effect of parturition, 530.
- bonemeal and dicalcium phosphate for, Tex. 225.
- calcium and phosphorus intake levels, effect on health and milk production, Miss. 520.
- cervical secretions, rheological properties during oestrous cycle, 315.
- dairy, estimation of initial live weight at each lactation, 521.
- dairy, legume silage for, 373.
- dehydrated sweetpotato meal v. ground shelled corn for lactating, Tex. 233.
- effect of feeding fat-soluble dyes on color of milk fat, Mich. 82.
- heavy-producing, preparturition milking, 236.
- length of calving interval, Mich. 83.
- live weight, relation to milk-energy yield, 235.
- menstruation frequency relation to conception in, 235.
- milk, fineness of grinding grain for, S.Dak. 234.
- milk production, *see* Milk production.
- milking, comparison of rotation pasture, Ind. 80.
- milking, economic limits in feeding of extra grain to, U.S.D.A. 819.
- Milking Shorthorn, rate and economy of milk production, Nebr. 80.
- mineral intake under free choice system of mineral supplementation, Miss. 520.
- on pasture, meat meal as supplementary protein source, 81.
- pH in rumen, in vivo studies, 82.
- physiological effect of molasses- and phosphoric acid-alfalfa silages, 374.
- relative consumption of Johnson grass hay and sorghum silage, Miss. 374.
- reproductive function, role of pastures in improving, U.S.D.A. 819.
- sweetpotato meal v. peanuts on vine as milk-producing feed for, Ga. 820.

## Cow(s)—Continued.

udders, *see* Udder.

value of supplementary pastures and silage as major sources of nutrients, N.C. 80.

## Cowpea(s)—

and other legumes, comparative forage production, P.R.U. 318.

and soybean proteins, comparative nutritive value, Ala. 700.

ascorbic acid in, relation to temperature, 606.

breeding, Tex. 180.

culture tests, Miss. 467.

curculio, studies, Ga. 806.

grown in different areas, mineral content, Ga. 854.

mosaic streak, N.C. 51.

plants, metabolism of ascorbic acid in, 804.

root rot resistance and yield of varieties, Tex. 202.

seedlings, sell size in primary root, relation to vitamin C, 24.

tests, Miss. 317.

varieties, relative resistance to *Agromyza phaseoli*, 223.

variety tests, Ga. 772, Ga. Coastal Plain 179.

vitamin content, N.C. 80.

weevil, life processes, effect of relative humidities, 219.

Cowpox outbreak, relation to vaccinia, 530.

Coyote food habits, 212.

## Crab apples—

budding on Malling rootstocks, 192.

French, effect of soils and soil treatments on roots, 481.

tests, Nebr. 42.

Crabgrass and peach trees, competition between for soil moisture, N.C. 42.

Cracca, insecticides from, 215.

## Cranberries—

carbon dioxide-oxygen and storage relations, 47.

polyploidy in, induced by colchicine, 460.

## Cream—

demand by consumers at retail stores in New York City, [N.Y.] Cornell 407.

flash-pasteurized, phosphatase reaction of, 85.

for making butter in South, 373.

frozen, keeping quality, 382.

holding, for butter making, S.Dak. 240.

homogenized raw, lipolysis in, factors affecting, 378.

phosphatase value, effect of acidified milk cans, 675.

ripening, development of aroma in, 823.

sour, acidity test, accuracy, effect of sampling method, Mich. 9.

sour, home preparation and use, U.S.D.A. 551.

sweet and sour farm-skimmed, enzymes in, relation to keeping qualities of butter, Ind. 80.

synthetic, experiments with, 85.

## Cream—Continued.

viscosity, factors affecting, Wis. 820.

Creamery water supplies of Alberta, bacteriological analysis, 380.

Creatine and creatinine, biochemistry, 413.

*Crenosoma mephitidis*—

in dogs, 383.

in foxes, newer aspects, 95.

Creolin as powerful fungicide, 492.

Cresols, low toxicity for mammals, 215.

Cricket, house, Conn.[New Haven] 65.

*Cronartium*—*fusiforme*, notes, U.S.D.A. 650.*ibicola*, *see* White pine blister rust.Crop(s)—*see also* Field crops, Forage crops, and specific kinds.

acreage, State trend in, more corn, hay, less cotton, Miss. 143.

best cultivation, depth and time, Miss. 467.

blower, new, design, Wis. 836.

cold resistance in, nature of, Nebr. 25.

difference in response to minor elements and magnesium, 316.

following corn fertilized with cyanamide and potash, 183.

horticultural, breeding, value of native material in, 189.

Insurance Corporation, Federal, reports, U.S.D.A. 113.

Irrigated, yields, effect of manure, legumes, and phosphates, Nebr. 33.

monthly prices, Del. 256.

muck soil, production and marketing, Ind. 42.

nutrient needs, plant color as key, Miss. 33.

of Costa Rica, 752.

or North Carolina, boron status, 317.

pests, agricultural and horticultural, in South Australia, 807.

pests, control methods, 41.

production increased, importance of insect control, Utah 508.

production machinery, U.S.D.A. 835.

reports, U.S.D.A. 116, 262, 549, 851.

residues as valuable source of plant food, Ind. 16.

residues, collecting, equipment, methods, and costs, 841.

response to fertilizers, relation to chemical tests, P.R.U. 16.

rotations, *see* Rotation of crops.*Sclerotinia* and *Fusarium nivale* outbreaks on winter sowings and withering, causes, 637.

southern, estimating, objective sampling in, 400.

yields, increase, from fertilizers, P.R.U. 206.

Croplands, abandoned, artificial reseeding with native and introduced grasses, Colo. 616.

## Crotalaria—

and corn rotations, N.C. 34.

for forage, Fla. 816.

- Crotalaria*—Continued.  
seed production from different planting rates, Ala. 616.  
seed, untreated, germination, effect of exposure on soil surface, Ala. 616.  
variety tests, Ga.Coastal Plain 179.
- Crotalaria stictica* as green manure for sugarcane, P.R.U. 34.
- Crown gall—  
growth substance in, 338.  
organism, nutrition, role of vitamins and metallic elements, 339.  
production by bacteria-free tumor tissues, 639.  
radiobacter, and hairy root bacteria, comparative physiology, 338.
- Cryptotermes brevis*, resistance of material to, P.R.U. 60.
- Ctenolepisma urbani*, behavior of, 656.
- Otenophyllus* genus, in North America, 513.
- Cube and bordeaux mixture, compatibility, 355.
- Cucumber beetle—  
striped, Ind. 65.  
western spotted, control in orchards, 362.
- Cucumber(s)—  
comparative resistance to nematodes, Miss. 477.  
cottony leak, notes, P.R.U. 51.  
diseases, P.R.U. 51.  
effect of root knot on, Ga.Coastal Plain 201.  
fertilizer tests, Ohio 189.  
fruits, effect of growth substances, Ind. 42.  
mosaic, diminished acreage due to, P.R.U. 51.  
parthenocarp in, 42.  
pickling, fertilization, N.C. 52.  
under different storage conditions, effect of waxing on physiological processes, 478.  
varieties, Ga.Coastal Plain 188.  
varieties, mildew-resistant, P.R.U. 42.
- Cucurbit—  
fruitfly, resistance of strains of bitter gourd to, 222.  
insects, insecticide tests with, Colo. 651.
- Cucurbita* spp., resistance and susceptibility to curly top in, 200.
- Culca quinquefasciatus*, new vector of *Plasmodium gallinaceum*, 360.
- Culicoides*, list of species in western Canada, 353.
- Culture bench, all-wood gravel, constructed of treated lumber, Ohio, 100.
- Culture media—  
bacteriological, synthetic soil for, 298.  
sterile, dispensing, automatic zero pipette, for, 156.  
stored, pH changes in, Vt. 374.
- Cunninghamella melnickeella* n.sp., description, 350.
- Cuprous oxide mixture, home-made, as citrus fungicide in Queensland, 648.
- Currant(s)—  
alpine, immune from blister rust, tests with staminate clone of, U.S.D.A. 336.  
diseases, control, N.Y.State 490.  
relation to white pine blister rust in New York State, 350.
- Cut-over lands—  
of northern Idaho, U.S.D.A. 265.  
of western Washington, settlement and opportunities, U.S.D.A. 697.  
settlement experience and opportunities on, Wash. 117.  
spruce-fir pulpwood, growth on, 199.
- Cyllene robiniae*, see Locust borer.
- Cynomyia cadaverina*, loci of olfactory end-organs in, 222.
- Cynthia cardui*, see Painted lady.
- Cypress, Italian, *Cytospora* canker of, 211.
- Cypripedium* leaf blotch, 789.
- Cystine—  
alkaline decomposition, qualitative studies, 726.  
in grassland herbage, 663.
- Cystopage*—  
*lateralis* n.g. and n.sp., description, 491.  
*subtilis* n.g. and n.sp., description, 491.
- Cytology, fundamentals, application to genetics and evolution, 171.
- Cytospora cenisia littoralis* n.f., studies, 211.
- Dacus—  
*cucurbitae*, resistance of strains of bitter gourd to, 222.  
*oleae*, see Olive fruitfly.
- Daffodil(s)—  
eelworm in seedlings, 349.  
smoulder or gray mold, 349.
- Dahlia(s)—  
levulose from, 737.  
varieties, Ga. 776.
- Dairy—  
animals, relative fertility of, 373.  
barn, experimental ventilation and insulation, Ind. 98.  
barns, open shed v. insulated and fully equipped, Wis. 835.  
cattle and dairy cows, see Cattle and Cows.  
equipment cleaning problem, detergents in, 824.
- farm(s)—  
financial success of, factors affecting, Utah 541.  
grass silage used on, Mass. 234.  
management, [N.Y.]Cornell 541.  
rotation with sweet corn as cash crop, N.H. 317.  
herds, number and size, N.H. 401.  
industry of New York, history, 261.  
industry, textbook, 699.  
plant equipment, *Pseudomonas putrefaciens* in, 524.  
plants, accounting for milk fat in, Vt. 374.  
production milestones, 233.  
products—  
action of mold inhibitors on, 377.

## Dairy—Continued.

- products—continued.  
 fat percentage in, determination, Pa. 9.  
 flavor development in by micro-organisms, 673.  
 for defense, Utah 520.  
 frozen, corn sweeteners for, 525.  
 frozen, manufacture, need of sanitary control in, 242.  
 oxidized flavor in, experiments with antioxidants, 523.  
 phosphatase production by micro-organisms, 85.  
 scoring, contestant judgments in, analysis, 120.  
 vitamin D in, methods of increasing, 566.  
 program, correlating with programs of other educational and regulatory agencies, 373.  
 region, Midwest, conservation and production adjustments in, 401.  
 replacements under New Hampshire conditions, economy of raising, N.H. 374.  
 sires, *see* Bull and Sire(s).  
 sterilizing equipment, electrical, for farm use, Calif. 103.  
 Dairying—*see also* Creamery, Butter, Milk, *etc.*  
 in four areas of State, relative opportunities for, N.H. 401.  
 letter of unusual interest on, 143.  
 place in southern farm program, 373.  
 Dairymen in wholesale milk areas, relation of liabilities to total assets, N.H. 401.  
*Dallatorrea* sp., notes, 811.  
 Dallis grass seed, harvesting methods, Mis. 317.  
 Dam, Missouri soil-saving, low-cost structure for farm plans for water management, Mo. 506.  
 Dam sites on upper tributaries of Columbia River, geology, 697.  
 Dandelions, proliferation from roots, 308.  
 Dark adaptation—  
 and experimental human vitamin A deficiency, 562.  
 course of, effect of fatigue, 863.  
 effect of thyroid administration and of  $\alpha$ -dinitrophenol, 707.  
*Daruca flum* on cereal rusts in South India, 342.  
 Date—  
 garden, California, air and soil temperatures in, 744.  
 palm fruit insects, tests to repel, Tex. 214.  
 palm, new species of *Ceratostomella* on, 502.  
 palm, rhizosis, relation to *Ceratostomella radicola*, 349.  
*Daucus carota* root, carotene in, cytological studies, 750.  
 Day length, *see* Photoperiodism.

- Death-watch beetle, destruction of wood by, relation to decay by *Phellinus cryptarum*, 659.  
*Decatoma amsterdamsensis* parasite of wheat jointworm, U.S.D.A. 514.  
 Deer—  
 mule, outbreak of hemorrhagic septicaemia, 830.  
 Virginia, *Cephenomyia* in, 383.  
 Defense industries, impact on rural communities, U.S.D.A. 852.  
 Deficiency diseases, *see* Diet deficiency and specific diseases.  
 Deficit spending, 399.  
 Dehydration—*see also* Drying.  
 work of regional research laboratories on, U.S.D.A. 723.  
 7-Dehydrocholestene isomer, structure, 581.  
 Delaware Station, notes, 573.  
 Delaware University, notes, 573.  
*Delphinium brownii*, extracts, insecticidal value, 215.  
 Delphinium diseases, 649.  
*Deltocephalus striatus*, vector of wheat mosaic, 312.  
 Democracy, challenge to, Iowa 264, 409.  
 Dendrochronograph, new, 295.  
*Dendroctonus*—  
*brevicornis*, *see* Pine beetle, western.  
*monticola*, *see* Pine beetle, mountain.  
 Department of Agriculture, *see* United States Department of Agriculture.  
 Depressions, post-war, 399.  
 Dermacentor—  
*andersoni*, discovery of ixovotoxin in, 853.  
*reticulatus* as camel tick in Manchoukuo, 676.  
*variabilis*, *see* Dog tick, American.  
 Dermatitis—  
 caused by tropical rat mite in Minnesota, 805.  
 in turkey poult, prevention by biotin, 668.  
*Dermatogys veligera*, snowshoe hare as new host to, 805.  
 Derris—  
 insecticides from, 215.  
 root infusion for sucking and biting lice of mammals, 510.  
 toxicity to potato leafhoppers, 69.  
 Desoxycorticosterone, absorption of pellets implanted in rat, 29.  
 Desserts, frozen—  
 corn sweeteners in, N.Y. State 270.  
 dextrose and corn sirup for, 382.  
 Detoxication mechanisms, 413.  
 Devil's shoestring—  
 as insecticide, Tex. 213.  
 possibilities as hillculture crop, Ala. 623.  
 Dextrins, reducing power, 733.  
 Dextrose, intravenously injected in rats, response to on vitamin B<sub>1</sub>-deficient diets, 887.  
*Diabrotica*—  
*duodecimpunctata*, *see* Corn rootworm, southern.

*Diabrotica*—Continued.

*11-punctata* on artichoke, Calif. 507.

*soror*, see Cucumber beetle, western spotted.

*vittata*, see Cucumber beetle, striped.

Diacetyl and benzoic acid, comparative bactericidal action, 790.

*Diaphania nitidalis*, see Pickleworm.

*Diaporthe citri*, cuprous oxide mixture for control on citrus, 648.

## Diarrhea—

chronic, role in production of vitamin deficiency syndromes, 275.

tropical, of calves in Puerto Rico, parasites associated with, 383.

Diatom, carotenoid-sensitized photosynthesis in, evidence for, 167.

*Diatraea saccharalis*, see Sugarcane borer.

Dicrocoelinae revision, with new species from North American birds, 384.

*Dicrocoelium dendriticum* in United States, 827.

*Dicymolomia pegasalis*, life history notes, 813.

*Didymella sepincolliformis* on rose, 503.

Diet(s)—see also Food(s) and Nutrition.

deficiency diseases—see also specific diseases.

and resistance to infection, interrelation, 507.

of children, see Children.

of frequent use in Puerto Rico, comparative nutritive value, 414.

of infants, see Infant(s).

vitamin A-free basal, 129.

Dietetics simplified, 124.

Dietitian, student, experiment in cooperative education, 555.

Digestive system, 124.

*Digitalis purpurea* flowering initiated by low temperature and light, 758.

*Digitaria*, seed germination studies, 187.

Dill seeds, embryology, 761.

Dinitro-o-cresol as locust poison, 509.

*Diocophyme renale*—

in dogs, 383.

life cycle, 828.

*Dioctria*, genus in North America, 222.

Dipeptidases, activation, 430.

1,4-Diphenyl semicarbazide as insecticide, U.S.D.A. 806.

Diphosphothiamin, functions, 502.

*Diphyllobothrium latum*, rate of growth, 213.

*Diplodia natalensis* on okra stalks in Alabama, U.S.D.A. 788.

*Dipodomys merriami*, animal reservoirs of, 823.

## Diptera of—

Quebec, additions to catalog, 223.

of Venezuela, 362.

*Dirofilaria immitis*, treatment with fuadin and sulfanilamide, 383.

## Disease(s)—

and comfort in relation to climate, U.S.D.A. 294.

deficiency, see Diet deficiency diseases and specific diseases.

milk-borne, 244, 673.

## Disease(s)—Continued.

of animals, see Animal disease(s) and specific diseases.

of man and animals, relation to mosquitoes, 512.

of plants, see Plant disease(s) and specific host plants.

resistance, inherited, physiological basis, 765, 789.

Disinfectants, studies, U.S.D.A. 676.

Distemper inclusion bodies, significance, 248.

Distilling industry in Maryland, economic aspects, Md. 694.

*Ditropinotus aureoviridis* parasite of wheat jointworm, U.S.D.A. 513.

*Ditylenchus dipsaci*—

control with volatile liquids, 63.

notes, 490.

Diversol, germicidal potency, 674.

Djenkolic acid, protein hydrolysis in presence of, Minn. 726.

Dodder, relation to curly-top-infected sugar beets and tobacco, 200.

## Dog(s)—

blood nitrogenous constituents, effect of kidney damage, 95.

choline in synthetic rations for, importance, 229.

*Crenosoma mcpitidis* in, 383.

*Diocophyme renale* in, 383.

feeding, studies, Ala. 818.

fly breeding in beach deposits of marine grasses, control, U.S.D.A. 806.

fly breeding in peanut litter, control, U.S.D.A. 806.

ingested phosphorus in bone and teeth, distribution, 273.

nutritional requirements, 368.

ovariectomy of grayhound bitches, effect on racing performance, 815.

riboflavin deficiency, 229, 230.

running fits in, relation to wheat gluten, Wis. 827.

tick, American, effect of length of day on activity and hibernation, 815.

tick, brown, as household pest, 224.

tick, brown, transmission of Q fever by, 386.

vitamin requirements and functions, 368.

Dogfish liver oil, effectiveness of ester and free forms of vitamin A in, 517.

Dog-wolf genetics, 314.

Dogwood root rot of young, pink, grafted stock, N.J. 802.

Dolichopodidae, new western, 360.

*Dothichopus* n.sp., description, 360.

*Dothigella*—

*aristidae*, notes, 792.

ulet leaf spot on Para rubber trees, 504.

*Dothideovalsa rutypoides* n.comb., taxonomic studies, 450.

*Dothiora*—

*berengertiana*, notes, N.J. 211.

*mali fructus* n.var., 789.

Dough, properties, factors affecting, 150.

Dourine eradication, U.S.D.A. 676.

Dove hybrids, interaction of antigens in, 614.

- Dove species, antigenic differences between, pictorial representation, 178.
- Dowicide A germicidal potency, 674.
- Dowitcher, food habits, 212.
- Dracoulacephala portola*, transmission of sugarcane chlorotic streak by, 645.
- Dragonflies, West Indian coenagrionine, life history notes, P.R.U. 807.
- Drain fly, Pacific, in homes, 64.
- Drainage—  
basin, Owens River, summary of 1940 forecast for, 444.  
controlled, 688.  
ditches, open, maintenance, 393.  
soil changes resulting from, Minn. 742.
- Drapcometer, methods of handling, 284.
- Drepanaphis* genus cast of Rocky Mountains, 809.
- Drinking glasses, cleansing methods and evaluating detergents, 717.
- Drinking water, minute amounts of lead in, determination, 584.
- Drosophila busckii* in milk, 222.
- Drought(s)—  
in South Africa, 16.  
migrants, adjustments after 3 years, Wash. 852.
- Drug(s)—  
analyses, Me. 700.
- Drug plants—  
and herbs, dehydration and processing, N.H. 392.  
and herbs, diseases of, U.S.D.A. 201.  
of Costa Rica, 752.  
possibilities of domestic production, U.S.D.A. 776.
- Drug products inspection, Conn.[New Haven] 550.
- Dry cleaning of textile fabrics, 285.
- Drying—*see also* Dehydration.  
of fruits and vegetables for preservation, U.S.D.A. 155.
- Duck(s)—  
and geese, breeding, management, and marketing, revision, 519.  
food plants of Illinois River Valley, 505.  
post-embryonic development in, variability of external forms, 613.
- Dust cloud, distribution of sodium arsenate and diluent in, 653.
- Dustling, *see* Spraying and specific crops.
- Dwarfism, hereditary, in mice, 177.
- Dyes, fluorescent, growth experiments with, 753.
- Dynamometer—  
drawbar, electric ultramicrometer circuit as, 395.  
simple, construction, 394.
- Dysdercus howardi*, biology, 808.
- Dysentery, infectious hemorrhagic, of swine, 243.
- Earth layers, saturated, mathematical analysis, 837.
- Earthworms, beneficial effect on soil properties, 158.
- Earwig, European, control, Conn.[New Haven] 65, U.S.D.A. 218.
- East coast fever, *see* African coast fever.
- Easter lilies, forcing problems in, 633.
- Eating utensils, cleansing methods and evaluating detergents, 717.
- Echinophaga gallinacea*, *see* Sticktight flea.
- Ecological—  
concept, correct interpretation of, 301.  
studies, methods of radiation measurement for, 162.
- Economic foreign policy for America, 399.
- Economic trends and national land policy, 263.
- Economics—  
agricultural, *see* Agricultural economics.  
international, research in by Federal agencies, 256.  
teaching, problems in, 400.
- Ecuador, studies, P.R.U. 287.
- Education, conservation in rural areas of United States, 119.
- Elgrass, wasting disease, 788.
- Egg(s)—  
albumin, *see* Albumin, egg.  
and egg products, chemical studies, U.S.D.A. 723.  
and poultry marketing, coordinated program, research in North Central States, 261.  
as protective food, 551.  
chalaza formation in, histological study, 315.  
containers treated with a mycostat, use in cold storage, 79.  
cooling and holding on farm, refrigeration for, Ind. 98.  
fresh dissected, detection of fertility by radio frequency, 518.  
fresh fertile and infertile, high frequency conductivity and dielectric effect, 315.  
from Rhode Island Red hens, length of incubation period, importance, Mass. 232.  
grades and relation of quality to price, size, and cleanliness, Ind. 103.  
hatchability, effect of environment and heredity, [Conn.] Storrs, 819.  
high and low quality fresh, differences, 667.  
incubation, *see* Incubation.  
interior quality of various breeds, 517.  
laying trials in Great Britain, mortality in, 253.  
legislation, review, in United States, 519.  
marketing in Los Angeles area, Calif. 850.  
measurements of long and short axes, relation to weights and volumes, 370.  
preservation by refrigeration, review, 668.  
production—*see also* Hens, laying.  
annual estimates, accuracy of short-interval trap-nesting, 370.

## Egg(s)—Continued.

## production—continued.

effect of height and location of

feed and water containers, 517.

fall and winter, of pullet progeny  
of selected sires, Del. 369.

365 day equivalent table, 517.

winter, fleshing mash v. heavy grain  
feeding for, N.Dak. 79.

quality studies with Storrs contest hens,  
518.

vitamin content, effect of incubation,  
819.

## yolk(s)—

ruptured, control by breeding, N.H.  
382.

stimulatory action on conidia of  
powdery mildew, 200.

weight and quality, effect of vege-  
table oils in rations, 372.

## Eggplant(s)—

bacterial wilt-resistant varieties, P.R.U.  
42.

blight-resistance studies, 404.

molds in markets, 639.

variety tests, Nebr. 42.

Eggshells, texture, relation to loss of weight  
during incubation, Mich. 667.

## Eimeria—

*acervulina* oocysts, sporulated, effect of  
variable dosages on chickens, 536.

*leporis* in cottontail rabbit, pathology,  
244.

*nieschulzi* and pantothenic acid infec-  
tion in rat, 828.

*nieschulzi* in rat, relation to vitamins  
B<sub>1</sub> and B<sub>6</sub>, 383.

*stiedae*, transmission from domestic to  
cottontail rabbit, 828.

*tenella*—

in poultry, sulfaguanidine mash  
for, 833.

infected chicks, hemorrhage control  
with vitamin K, 684.

resistance to, in poultry, inheri-  
tance 461.

stage in life cycle, effect on re-  
sults with sulfur, 537.

El Cerrito, New Mexico, culture and com-  
munity stability, U.S.D.A. 697.

## Electric—

light, carbohydrate formation in, effect  
of omission of red and blue-violet rays  
from, 454.

mixers and beaters for household use,  
equipment studies, Ind. 142.

## Electricity, uses on farm, U.S.D.A. 835.

## Electrification—

rural, need for technological research,  
690.

rural, treatise, 120.

work of Bureau of Agricultural Chemis-  
try and Engineering on, relation to  
national defense, U.S.D.A. 835.

## Electrodes, graphite, shaping lathe for, 724.

Electrokinetics, electroviscous effects, Minn.  
724.

## Elements—

minor, relation to plant and animal  
nutrition, 23.

trace, role in plant nutrition, 603.

*Eltopia athasaria*, notes, Conn.[New Haven]  
65.

## Elm—

American, response to loose and briquette  
fertilization in greenhouse, 786.

bark beetle, native, internal application  
of chemicals to prevent attacks on  
elms, U.S.D.A. 72.

bark beetle, smaller European—artifi-  
cially feeding various substances to,  
technic, 639.

internal application of chemicals to  
prevent attacks on elms, U.S.D.A.  
72.

prothetely in, 659.

transmission of Dutch elm disease  
by, 71.

bark beetle, transmission of Dutch elm  
disease by, Conn.[New Haven] 50.

bark beetles, control, Conn [New Haven]  
65.

borer, artificially feeding various sub-  
stances to, technic, 639.

Chinese, grown in Michigan, strength  
properties, Mich. 635.

## disease, Dutch—

control, 490.

spread, transmission, and control.  
Conn.[New Haven] 50.

studies, Conn.[New Haven] 64,  
U.S.D.A. 201, 788.

transmission by *Scolytus multi-*  
*striatus*, 71.

diseases and other disturbances, 802.

mosaic disease, graft-transmissible,  
U.S.D.A. 788.

trees, internal application of chemicals  
to kill and prevent bark beetle attack,  
U.S.D.A. 72.

wood, bark beetle infested, Dutch elm  
disease fungus in, 72.

## Elisinae—

*dolichi* n.sp., description, 202.

genus, revised description and type  
species, 450.

n.sp. on hosts of economic importance  
52.

*Embolocera sauzaii* on artichoke, Calif. 507.Embryonic development, duration of, varia-  
bility and inheritance, 610.

## Embryos—

*Datura*, isolated, coconut milk factors  
essential for growth and development,  
602.

homozygous yellow mouse, increased vi-  
ability in new uterine environments,  
766.

*Emilia scabra*, virus disease of, 792.*Empoasca fabae*, see Potato leafhopper.

## Encephalitis—

antibodies, western equine and St. Louis,  
in sera of mammals and birds, 385.

canine, and post-encephalitis, 243.

## Encephalitis—Continued.

human and equine, 383.

human, due to equine encephalomyelitis virus, 830.

St. Louis and western equine types, 385.

St. Louis and western equine viruses, isolation from *Culex tarsalis*, 386.

St. Louis, susceptibility of horses to virus of, 252.

St. Louis, virus, attempts to transmit to baby chicks, 95.

*Encephalitozoon cuniculi* infection in rabbit, 244.

## Encephalomyelitis—

avian—

infectious cycle, 684.

present status, 833.

status, 243.

studies, U.S.D.A. 676.

transmission, 243.

canine, 243.

equine—

antigenic properties of pigeon-brain-tissue vaccine, 528.

distribution of vectors in Massachusetts, 252.

in chicks, pathology, 684.

mosquitoes of Minnesota as vectors, 252.

relation to human encephalitis epidemic in Saskatchewan, 244.

relation to mosquitoes, 512.

studies, 528, U.S.D.A. 676.

susceptibility of mammals and birds to, 528.

virus, cause of human encephalitis, 830.

virus, susceptibility of dogs to, 390  
western virus, comparative susceptibility of wild and domestic birds and animals, 94.

western virus, isolation from prairie chickens, 528.

St. Louis and western equine, viruses in horses and fowl, neutralizing antibodies against, 683.

sporadic bovine, Tex. 243.

sporadic bovine, filtration of causal agent, 242.

Endive yellows disease, studies, 490.

*Endoconidiophora* sp., notes, 803.

## Endocrine—

control of insect development, 651.

glands, 124.

Endocrinology, treatise, 242.

Engineering work of U.S. Department of Agriculture, U.S.D.A. 835.

Engines, internal combustion, oil filters for, Nebr. 98, 304.

*Enicmus minutus*, life history, 809.

Enterococci, hemolytic, in milk, sources, 238.

Enterohepatitis, infectious, see Blackhead.

Enterotoxemia of lambs, Colo. 676, Tex. 243.

## Entomological—

nomenclature and literature, 806.

publications, bibliography of, 64.

Entomologists, contributions to Hawaii's welfare, 65.

Entomology—see also Insect(s).

defense applications of, U.S.D.A. 806.

economic, poison or insecticide in, 64.

recent advances in, for control operations, 214.

## Enzyme(s)—

action, mechanism of, 128.

chemistry of, U.S.D.A. 723.

nonproteolytic, 123.

proteolytic and nonproteolytic, 413.

proteolytic, *Bromelia pinguin* as source, P.R.U. 287.

Ephemeral fever in Australian cattle, 530.

*Ephestia*—*cautella*, see Almond moth.*elutella*, see Tobacco moth.*Ephydra hians*, food habits, 358.*Epicauta pennsylvanica*, see Blister beetle, black.*Epilachna varivestris*, see Bean beetle, Mexican.*Episthium gallinum* n.sp., description, 539.*Epitrix cucumeris*, see Potato flea beetle.

Equine diseases, sulfanilamide for treatment, 390.

Equine species, diseases of newborn in, 243.

*Eriophyes*—

n.sp., description, 224.

*shedoni*, life history, habits, and control, 661.*vacinii* n.sp., notes, 224.*Eriosoma lanigerum*, see Apple aphid, woolly.

Erosion, see Soil erosion.

*Erosomyia mangiferae*, notes, 221.*Erwinia amylovora*, serological studies, 500.*Erysipelothrix*—

Australian strains, 244.

identification and relation to *Listeria*, 529.*Erysiphe cichoracearum*—development and vitamin B<sub>1</sub>, 200.

notes, U.S.D.A. 788.

*Erythroneura comes*, see Grape leafhopper.*Escherichia coli*, strains, action of sulfanilic guanidine on, 386.

Estates, farm and city, location of heirs and value of inheritances, 258.

Itch virus, severe, inclusions induced by, 792.

Ethyl alcohol, production from cull potatoes and other farm crops, Idaho 443.

Ethyl glycinate hydrochloride, reaction with Grignard reagents, 725.

Etiolation prevention, 755.

Eucalyptus plantings, effect on soil, nutrient requirements, and transpiration, 50.

Eucharidae, host preferences and habits, 223.

*Euchlaena*, *Tripsacum*, and corn, genetic and cytological relations, Tex. 180.*Eucordylea humtella* as rhododendron pest, 64.*Eufalloides* new genus, erection, 809.*Eula*—*quadrifasciana* in apple orchards, N.Y. State 652.

*Eulia*—Continued.

*velutinana* in apple orchards, N.Y. State 652.

*Eumecurus* spp. on narcissus bulb, control, U.S.D.A. 507.

Eunomymous scale, control, 651.

*Eupelmella vesicularis* parasite of wheat jointworm, U.S.D.A. 514.

*Eupelmus*—

*allynii* parasite of wheat jointworm, U.S.D.A. 514.

*coccidis* parasite of praying mantid egg cases, 812.

*Euphorbia corollata* in Appalachians, 20.

*Eusimuliculus* spp. and varieties, 20.

*Eurotia lanata*, germinability and early development, effects of microecological factors, 751.

Eurypygidac, descriptive catalog, 351.

*Eurytoma*—

*parva* parasite of wheat jointworm, U.S.D.A. 513.

*phoebeus* parasite of wheat jointworm, U.S.D.A. 514.

*semitis* n.sp., description, 364.

Evans, W. H., obituary note, 144.

Evaporation and transpiration, U.S.D.A. 294.

Ewe(s)—see also Sheep.

breeding, relation of temperature and breed of ram to, Ga. 816.

breeding, wintering, cull beans and cottonseed meal for, Mich. 78.

dipping for increased wool production, Ind. 76.

early breeding, N.C. 77.

gummer, fattening, S.Dak. 228.

iodine supplementation for, satisfactory use, Colo. 602.

milking ability, relation to lamb and mutton production, U.S.D.A. 662.

time of ovulation and rate of sperm travel, 465.

wintering, leguminous hay for, Ind. 76.

Exanthema, vesicular, of hogs, relation to virus diseases of plants, U.S.D.A. 337.

## Experiment stations—

forest—see Forest.

list of bulletins, U.S.D.A. 572.

Experiments designed factorially, diagrammatic representation of results, 301.

Eye anomaly in albino rat, inheritance, 766.

Eye function, relation to nutrition, 415.

*Fabraea maculata* on quince, control, 60.

## Fabrics—see also Textile(s).

breaking strength, comparison, 282.

cotton corduroy, for boys' clothing, properties, 715.

damage from firebrat, 508.

flameproofed, apparatus for testing, 286.

flexibility, effect of relative humidity, 284.

measuring stiffness in, comparison of methods, 283.

other than cotton and linen, shrinkage determination, tension presser for, 715.

pliability, evaluating with Planoflex, 508.

## Fabrics Continued.

protection against damage by microorganisms, U.S.D.A. 714.

studies, U.S.D.A. 714.

terms relating to hand of, 282.

treatment for protection against moths, 286.

wearing qualities, determination by air flow measurements, 139.

woollen, see Woollen.

Factor V, or filtrate factor—

and vitamin I complex, 135.

in polished rice, 135.

Fade Ometer tests, variables encountered in, 139.

Falkland Islands, natural resources, 718.

Family(ies)—see also Farm family(ies).

diets, methods of improving, U.S.D.A. 716.

expenditures for furnishings and equipment: urban, village, farm, U.S.D.A. 141.

farm in machine age, Iowa 264.

farm, village, and small-city, consumption patterns at different income levels, U.S.D.A. 716.

on relief, 5 ct. milk in diets of, U.S.D.A. 716.

Farina, enriched, definition and standard of identity of Federal Food, Drug, and Cosmetic Act, 552.

## Farm(s)—

and ranch products, trends in market prices, Mont. 547.

animals, see Livestock and Animal(s).

building(s)—

appraisal, Mo. 693.

classifications, relation to soil productivity, 260.

in land use planning, 390.

planning for use rather than for extreme permanence, 844.

rat-proofing methods, Iowa 805.

southern, needed research on, 600.

business planning in Bluestem Belt, Kans. 541.

business summary, Mich. 603.

commodity prices and length of haul, 400.

coordinating with industrial trends, U.S.D.A. 852.

costs, income, profits, etc., Okla. 402.

cotton-corn, conservation on, Okla. 602.

Credit—see also Agricultural credit.

Administration report, U.S.D.A. 544.

crops, lightning injury to, N.J. 202.

electricity on, see Electricity.

engines, power alcohol for, 338.

enterprises, costs and returns from, [N.Y.] Cornell, 107.

family(ies)—see also Family(ies).

expenditures for clothing by, U.S.D.A. 141.

labor, availability and use, Ala. 691.  
of Iowa, incoming and outgoing payments, Iowa 845.

## Farm(s)—Continued.

## family(ies)—continued.

- owner, in poor agricultural areas and cropper farm families in rich agricultural areas, Miss. 265.
- resettlement and rehabilitation, N.Dak. 266.
- socioeconomic condition, measuring stick for, Miss. 141.
- tenant, improving levels of living, Miss. 875.
- with low incomes, expenditures of, Wis. 876.
- fish ponds, Ala. 651.
- homemakers, types of garments owned by, Miss. 141.
- houses, minimum requirements for, U.S.D.A. 430.
- housing, adequate, on limited income, 843.
- in Wales, financial results on, 402.
- income—

Film strips of U. S. Department of Agriculture, U.S.D.A. 267.

Financing agriculture, textbook, revision, 120.

Fir, Douglas, seed germination, relation to light and temperature, 50.

Fire(s), forest, *see* Forest fire(s).

Fire insurance companies, farmers' mutual, in West Virginia, W.Va. 545.

## Firebrat—

action of derris and rotenone on, 651.

baits, barium compounds as poisons in, 509.

damage to fabrics and paper, 508.

Fireplaces and chimneys, design, construction, cleaning, and repair, U.S.D.A. 844.

Fireweed honey, composition, 702.

## Fish(es)—

Bengal, liver and body oils, vitamin D in, 136.

Bengal, nutritional studies, 121.

Bengal, vitamin A in, 129.

canned, as meat substitute in summer mink ration, 516.

extract powder, growth-promotion value, Nebr. 76.

Indian, vitamin A in liver and deposit fats, 128.

liver oils, applicability of spectrophotometric determination of vitamin A to, 585.

liver oils, units of vitamin D and vitamin A in, 151.

of Shanghai, vitamin A in, 864.

of Texas, Tex. 212.

oils, rancidity in, peroxide values for, determination, 733.

ponds, farm, Ala. 651.

ponds, response to fertilization, Miss. 63.

populations, natural and domesticated, responses of *Sd* factor in, 765.

raw carp, vitamin B<sub>12</sub>-destroying factor in, fatal to fur animals, 534.

warm water game of United States, culture, 351.

Fishery products, home canning, 414.

Flannels of different proportions of new and reprocessed wool, properties, 570.

Flavin requirements of chicks, Ind. 76.

## Flax—

anthracnose in California, damage from, U.S.D.A. 50.

as winter crop for south Texas, Tex. 180.

breeding, Tex. 180, U.S.D.A. 771.

cold tolerance in, 471.

cross, inheritance of rust reaction in, 311.

culture, tests, Tex. 180.

disease resistance, and improved seed and oil quality, U.S.D.A. 771.

domestic, preparation and mill processing, 618.

fiber, microscopical studies, Ga. 772.

fiber, processing, U.S.D.A. 835.

fiber, studies, U.S.D.A. 772.

production and climate of North Dakota and Minnesota, N.Dak. 112.

rust prevention by borax, U.S.D.A. 336.

seeding, fertilizer, and harvesting tests, Ga. 772.

stem break, browning, and seedling blight prevention, 206.

variety tests, Ga. 772, Nebr. 33, Tex. 180.

variety yield differences, factors affecting, N.Dak. 640.

wilt in New England, 642.

## Tea beetle—

control, relation to control of *Alternaria solani* on tomato, U.S.D.A. 200.

pale-striped, studies, Ga. 807.

leahopper, garden, studies, Tex. 214.

**Fleas—**

- comparison of rodent and burrow populations, 362.
- parasites of pikas in North America, 513.

**Flies—**

- as carriers of poliomyelitis virus in urban epidemics, 512.
- role in dissemination of brucellosis, 527.

**Flood(s)—**

- and storms, U.S.D.A. 294.
- control by land treatments, U.S.D.A. 294, 744.
- forecasting, U.S.D.A. 294.
- forecasting service in Pennsylvania, 295.
- great, meteorology of, in eastern United States, 445.
- hazards and control, U.S.D.A. 294.
- mountain, and vegetation, 592.
- of August 1935 in Muskingum River Basin, Ohio, 98.
- Ohio River, probability of recurrence, 157.
- potential, in Sacramento Valley, 414.

Floor, precast tile beam, Iowa 100.

**Flour—see also Bread.**

- and related products, definitions and standards of identity of Federal Food, Drug, and Cosmetic Act, 552.
- baking quality in, Nebr. 6.
- enriching, milling aspects of, 553.
- national, for bread, British M.R.C. specifications, 553, 554.
- oxidation-reduction systems in, dropping mercury electrode in study of, 583.
- wheat malt dosage, diastatic activity, and gassing power, relations, 737.
- wheat, protein in, photometric determination method, 155.
- white, milling, loss of thiamin and nicotinic acid in, Wis. 854.
- whole wheat and clear, thiamin in, 708.

**Flower(s)—see also Plant(s), flowering and ornamental.**

- coloration, 163.
- pest control methods, 41.
- seed, germination standards, need for 622.

Fluid suspension, microscopic particles in, method for counting, 309.

Flukes from fowl and other birds, 539.

**Fluorine—**

- assimilation by rats during continuous and intermittent dosage, 127.
- constant concentration in diet, adaptation of rat to, 126.
- dietary, assimilation, effect of calcium and phosphorus, 559.
- effect on sheep, Ind. 76.
- effect on vitamin D activity in rachitic rats, 137.
- in soils, determination, U.S.D.A. 740.
- spray residue removal from fruit sprayed with natural cryolite, 356.

Fluorosis, chronic endemic dental, 559.

Foal, congenital anomalies in, 460.

Folk songs, American, Negro's contribution to, 698.

**Food(s)—see also Diet(s).**

- analyses, Me. 700.
- and Drug Act, fitting ice cream in, 382.
- and Drug Administration, wheat flour and related products, definitions and standards of identity, 552.
- and food customs, Hawaiian and Pacific, 121.
- and nutrition, laboratory and business relation in, 550.
- and nutrition, needed research in, 550.

- industries, new group of sterilizing agents for, 377.

- most common, vitamin tables of, 864.

- of Ceylon, analysis, 700.

- of Shanghai, vitamin A in, 864.

**preservation—**

- centers, community, U.S.D.A. 414.

- changes in dietary value during, 561.

- work of regional research laboratories on, U.S.D.A. 723.

- processing, Ga. 723.

- processing and colloidal stabilizers, 823.

**products—**

- fermented, yeasts in, N.Y.State 550.

- inspection, Conn.[New Haven] 550.

- microbiology of, U.S.D.A. 723.

- proteins of, U.S.D.A. 723.

- stored, insects infesting, methods used in rearing, 507.

- stored, Lathridiidae in, 809.

- quick frozen, industry and vitamins, 561.

- quick frozen, nutritive value, 552.

- rational in Germany, U.S.D.A. 257.

- resources of Hawaii, symposium, 700.

- selection and preparation, U.S.D.A. 700.

- situation, national, U.S.D.A. 116.

- stamp plan, applied to consumption of fats, 401.

- stored, insects affecting in South Australia, 807.

- stored, mycostatic salts to prevent mold growths on, 514.

## Food(s)—Continued.

sufficiency, German research institutions working on, 430.

Tanganyika, nutritive value, 855.

trace metals and total nutrients in, Mass. 413.

used in Puerto Rican dietary, nutritional studies, 414.

vitamin A in, effect of processing, 276.

vitamin A values, U.S.D.A. 707.

vitamin B<sub>2</sub> determination in, 151.

vitamin B<sub>6</sub> in, chemical test for, 278.

vitamin C in, effect of processing, 279.

vitamins in, U.S.D.A. 700.

## Foot-and-mouth disease virus—

differentiation of type in Java, 247.

effect of sodium bifluoride and sodium silicofluoride, 249.

## Forage(s)—

crops and climate, U.S.D.A. 294.

crops, manganese in, effect of calcium and phosphorus, 305.

crops, variety tests, Ga.Coastal Plain 179, Miss. 772.

grasses, *see* Grass(es).

harvesting machines, new developments in, 397.

moisture determination in, 154.

poisoning, *see* Plants, poisonous, and specific plants.

studies, N.C. 34.

young protein-rich green, ensiling with dried whey, 821.

## Forest(s)—

activities under impact of war, U.S.D.A. 785.

canopies, rainfall interception by, 15.

climax, of Upper Peninsula of Michigan, 335.

cover and soil freezing, 444.

effect of thinning on reproduction, Vt. 335.

entomology problems, 353.

Experiment Station, Syracuse, experimental planting, 785.

fire prevention, fire-fighting plans and equipment, U.S.D.A. 635.

fire protection work, U.S.D.A. 785.

fires, training of personnel and combating and reducing hazards from, U.S.D.A. 200.

hardwood, of central New York, nutrient content of freshly fallen leaf litter in, 446.

humus layers, revised nomenclature, [N.Y.]Cornell 298.

national, and climate, U.S.D.A. 294.

nursery fertilizer studies, Conn.[New Haven] 16.

planting stock, production and distribution, Conn.[New Haven] 49.

reducing losses from tree diseases in, U.S.D.A. 802.

replacement rates in Colorado Headwaters area, 685.

research in lower South, two decades of, 785.

## Forest(s)—Continued.

resources of Upper Peninsula of Michigan, U.S.D.A. 49.

seeds, collection and handling, U.S.D.A. 197.

soils, effect of litter removal and liming, Conn.[New Haven] 16.

species, light requirements, Vt. 335.

species, native and introduced, N.H. 335.

trees, *see* Tree(s).

## Forestry—

in farm management, 266.

in Mexico, 335.

publications, U.S.D.A. 197.

*Forficula auricularia*, *see*, Earwig, European.

## Foulbrood—

American, purported resistance of bees to, 364.

American, queen rearing for resistance to, Tex. 214.

European, etiology, 223.

Fowl(s)—*see also* Chick(s), Chicken(s), Hen(s), Poultry, etc.

and guinea hen, reciprocal crosses, 767.

bred for resistance to neoplasms, 314.

hereditary chondrodystrophy in, 461.

hereditary congenital baldness in, 613.

lethal embryonic wing mutation in, 462.

paralysis, *see* Paralysis.

pox virus, nasal instillation in chickens and in mice, 245.

pox virus, propagation in avian eggs, Ill. 88.

semilethal mutation affecting length of upper beak and long bones, 462.

## Foxes—

digestibility studies, 369.

digestion and absorption by, 79.

feeding value of soybean meal and meat meals, 368.

lungworm records from, 534.

males, polygamous, frequency of use, 461.

red summer food, in Great Britain, 212.

silver, nicotinic acid deficiency in, U.S.D.A. 676.

silver, streptococcal arthritis and septicemia in, 534.

silver, vitamin A deficiency in, 368.

vitamin A in nutrition of, 212.

## Frankliniella—

*fusca*, *see* Tobacco thrips.

*occidentalis* on seedling cotton, 352.

*schultzei* on tomato, control, 798.

Freight rates, railroad, on perishable agricultural shipments, index numbers, U.S.D.A. 114.

French West Africa, physical features, population and industry, U.S.D.A. 257.

Frost injury to cereals in heading stage, 469.

Fructose polysaccharides in grasses adapted to Iowa, 736.

Fruit(s)—*see also* Orchard(s), Apple(s), Peach(es), etc.

acres, production, price, etc., Del. 256.

## Fruit(s)—Continued.

auctions, New York and Chicago, Washington apples on, Wash. 850.  
 boron requirements, N.H. 326.  
 bramble, varieties, Ga. 776.  
 breeding, N.Y.State 477.  
 breeding program, objectives and methods of distributing new varieties, N.Y.State 189.  
 canned, *see* Canned fruits.  
 chemical studies, U.S.D.A. 723.  
 citrus, *see* Citrus.  
 climatic adaptation, U.S.D.A. 294.  
 culture in South Dakota, questions and answers on, S.Dak. 43.  
 diseases in Idaho, U.S.D.A. 788.  
 diseases on New York market, U.S.D.A. 788.  
 dried, vitamin retention by, 560.  
 fertilizer and cultural work, N.Y.State 189.  
 fertilizer tests, N.Y.State 477, Tex. 149.  
 freezing preservation, 552.  
 fresh, complementarity relations, 400.  
 gray mold and some host plants, 798.  
 growing in New York, relation to soils, [N.Y.]Cornell 297.  
 insects, studies, N.Y.State 506, Tex. 243.  
 juice beverages, data on, Conn.[New Haven] 550.  
 juice concentration by freezing and centrifuging, 481.  
 juices, processing, N.Y.State 550.  
 market diseases of, U.S.D.A. 796.  
 methyl bromide treatment after harvest, effect on color, 480.  
 minor, for New York gardens, N.Y.State 631.  
 moth, oriental—  
     and *Triohogramma*, 64.  
     biological control, 215.  
     control, Conn.[New Haven] 64, 65, Ind. 65.  
     control, relation to oil deposits on quinces, N.Y.State 652.  
     insecticides for, N.Y.State 652.  
     parasites, Ind. 65.  
 new seedling productions of 1940, 329.  
 of California, utilization, Calif. 500.  
 pest control methods, 41.  
 pigmented, and their juices, ascorbic acid in, 560.  
 plants, damage by freeze of November 1940, 329.  
 plants, hardy, pruning, U.S.D.A. 43.  
 preservation by commercial dehydration, U.S.D.A. 155.  
 pressure testers and practical applications, U.S.D.A. 628.  
 production, long-term forecasting, 401.  
 products, possibilities for making by farmer, N.Y.State 702.  
 propagation and breeding, Tex. 189.  
 retailing, in New York City, 261.  
 riboflavin content, 869.  
 seedlings, failure to respond to vitamin B<sub>1</sub>, 43.

## Fruit(s)—Continued.

small, breeding, Tex. 189.  
 small, pruning, U.S.D.A. 43.  
 stone, brown rot, value of methyl bromide on, 798.  
 stone, buckskin disease, 200, 210.  
 sun-drying, methods and equipment, Calif. 590.  
 tree(s)—  
     coating effective against rabbits, Mich. 63.  
     diseases in Cape Province, control, 59.  
     dwarf, and Malling rootstocks, N.Y.State 189.  
     effect of Nov. 1940 blizzard, 326.  
     leaf roller control and oil deposit, 355.  
     leaf roller in apple orchards, N.Y.State 652.

- Georgia Station, report, 876.
- Gibberella saubinetii*, barley infected with, emetic principle in, concentration and characterization, 205.
- Gilpinia*—  
*frutetorum*, notes, Conn.[New Haven] 65.  
*polytoma* and *G. hercyniae*, taxonomic status, 813.  
*polytoma*, diapause and related phenomena in, 864, 814.
- Ginkgo biloba*, *Xylaria* pathogenic to, 649.
- Girls—  
 American, body measurements for garment and pattern construction, U.S.D.A. 140.  
 blood sedimentation rate in, 857.  
 high school, blood studies, 555.  
 school-age, clothing for, Miss. 571.
- Gizzard erosion—  
 and cholic acid in chicks, effect of milk on, 231.  
 causes, U.S.D.A. 662.  
 in chicks, effect of diet, 518.  
 incidence, 231, N.H. 382.  
 prevalence and significance, 536.
- Gladolus—  
 corms, adsorption of mercuric chloride by, U.S.D.A. 197.

## Gladiolus—Continued.

corms treated with chemicals, simultaneous formation of a  $\beta$ -gentiobioside and a  $\beta$ -glucoside in, 753.  
thrips control, Ind. 65.  
treatise, 197.

Glanders bacilli, susceptibility of rabbit to artificial infection, 677.

## Glands—

and their functions, 242.  
preputial, of female mouse, response to testosterone propionate, 464.

*Gliocladium*, mold toxins in, 338.

*Gloeosporium*—

*manihoti* dieback of cassava, P.R.U. 51.  
new species, 789.  
sp., cuprous oxide mixture for control on citrus, 648.  
spp. relation to latent infection in tropical fruits, 501.  
like fungus affecting Chinese chestnuts, 503.

*Glomerella cingulata*, spore germination tests of fungicides for, variation in, 340.

Glomerulonephritis in domestic animals, 529.

Glucose dissimilation by *Chaetomium funicola*, 727.

## Glutathione—

in wheat germ for bread making, use of yeast to destroy, 701.  
or glutathione-ascorbic acid, treatment of successive generations of rats with, 467.

*Gnathocerus cornutus*, *Tribolium confusum*, and *Trogoderma versicolor*, competition in populations of, 513.

## Goat(s)—

dairy, milk production and fleshing, relation to diet, U.S.D.A. 662.  
experimental osteodystrophic diseases in, 383.  
lousy, sulfur feeding to, Tex. 214.  
spleen vaccine, dried, immunizing value against rinderpest in buffaloes, 382.  
thyroidectomized, growth response to artificially formed thyroprotein, 822.

Godetia wilt disease, 801.

Gold and the monetary system, 399.

Gold problem and price level, 399.

## Gonad(s)—

chick and duck, sex differentiation of, 462.  
response of male rats to experimental hyperadrenalinism, 463.

Gonadectomized albino rats, sex difference in growth in, 466.

Gonadin, effectiveness in hypophysectomized immature female rats, relation to mode of administration, 464.

Gonadogen, response of gonads of chick embryos to, 179.

## Gonadotropic—

antagonism in mature rats, 30.  
extracts, effectiveness of heme in augmentation from different sources, 465.  
hormone, site of elaboration, 31.

## Gonadotropic—Continued.

material from green plants, variations in, relation to season and pH of fresh juice, 29.

Preparations, effect of increasing number of daily injections on immature rat ovaries, 466.

preparations, follicle-stimulating action, selective neutralization, 462.

## Gonadotropin—

chorionic, effect on atrophic genitalia of underfed male rats, 30.

effect on mammary glands of hypophysectomized rats, 670.

equine, 49-hr. assay test for, 464.

equine, use in mare and cow, 768.

time and rate of appearance in pregnant mare serum, 464.

Gooseberry diseases, control, N.Y.State 490.

Gopher, experimental host for *Trichinella spiralis*, 805.

Gourds, culture, uses, identification, etc., Minn. 191.

Government, local, needed reorganization in Ozark land use adjustment areas, Mo. 118.

Gaussian follicle, growth and time of ovulation in rat, 29.

Grain(s)—see also Cereal(s) and Oat(s), Rye, Wheat, etc.

accreases, production, price, etc., Del. 250.  
brewers' dried and distillers' corn dried, compared with shelled corn for net energy value, 515.

companies, farmers', accounting for, 546.  
cost of production, Ind. 103.

elevators, cooperative, in North Dakota and Montana, U.S.D.A. 695.

fineness of grinding for milk cows, S.Dak. 234.

inspection laboratory, Montana, service of, Mont. 469.

low- and high-test weight, feeding values for poultry, S.Dak. 371.

marketing, cooperative, in United States, U.S.D.A. 111.

moisture determination in, 151.

of Alberta, selenium in, 449.

plat technic studies with, 450.

small, and corn, comparative yields, U.S.D.A. 772.

small, effect of climate and weather, U.S.D.A. 204.

small, nutritive relations of boron to, 603.

small, seed, merits of fanning-mill grading, Nebr. 33.

small varieties, Miss. 33.

smut, see Smut and specific grains.

storage, engineering problems in, 397.

storage on the farm, N.Dak. 101.

## Gramicidin—

for elimination of chronic form of mastitis, 90.

toxicological and pharmacological properties, 829.

Granary beetles, interspecific competition in populations of, 513.

# Grape(s)—

aerial propagation, 484.  
American, and hybrids, causes of resistance to mildew, 799.

assimilation of plant food in, effect of leafhoppers, Ind. 65.

berry moth, N.Y.State 652.

black measles and little leaf, differentiation from Pierce's vine disease, 800.

boron deficiency in, 48.

breeding, Tex. 189.

bud-graft method, time limits, 484.

California, maturity studies with, 484.

culture, research problems in plant protection for, 799.

diseases and insects, control, U.S.D.A. 783.

diseases, control, N.Y.State 490.

downy mildew control, 800.

effect of naphthalenacetic acid on shattering, 631.

in storage, *Botrytis* rot of, fungicide tests for, 501.

juices, blending, Tex. 267.

leafhopper, studies, Tex. 213.

lightning injury to, N.J. 202.

maturity studies, N.Y.State 435.

## muscadine—

angular leaf spot, symptomatology and etiology, 648.

diseases of, Ga. 789.

shoots, carbohydrate changes in during growing season, 484.

northern-type, rootstocks for, Ga. 776.

performance, relation to time of pruning, 196.

Pierce's disease studies, U.S.D.A. 336.

pruning, U.S.D.A. 43.

root rot resistance, Tex. 202.

rootstocks for, N.Y.State 477.

varieties, Ga.Coastal Plain 188, Miss. 477.

varieties for southern Great Plains area, U.S.D.A. 776.

variety tests, Ga. 776.

# Grapefruit—

and juice, riboflavin content, 869.

clonal selection with respect to yield, 48.

fertilizers for, P.R.U. 326.

Florida, ascorbic acid concentration in juice, factors affecting, 869.

# Grapevine(s)—

effect of Korean lespedeza cover crops, Ga. 776.

## Pierce's disease—

and alfalfa dwarf, association, U.S.D.A. 336.

development and spread, 200.

notes, 800.

red leaf prevention by mite control, 500.

*Grapholita molesta*, see Fruit moth, oriental.

Grass(es)—see also Grassland(s), Meadow(s), Pasture(s), etc.

adapted native and introduced, establishing stands, Nebr. 33.

# Grass(es)—Continued.

adapted to Iowa, fructosan content, 736.  
and cereals, intergeneric hybridization, 763.

and clover mixture, *Anguillulina dipsaci* from tulip root oats injurious to, 492.

as hay and as silage, conservation of nutrients in, Vt. 374.

barnyard, root and stem rot relation to *Anacetrinus deplanatus*, 220.

boron for, field trials with, 341.

breeding, Tex. 180.

comparative water usage and depth of rooting, 318.

diseases in Kentucky, relation to grass improvement, 489.

diseases in Michigan, host and pathogen indexes, U.S.D.A. 788.

diseases in Wisconsin, U.S.D.A. 788.

drying, 397.

early spring killing in Alberta by low-temperature basidiomycete, 341.

ensiling and inclusion of types of silage in dairy ration, Miss. 374.

fertilized, forage production, P.R.U. 34.

for athletic fields and effect of peat on turf, 469.

forage, of California, cytological study, 174.

forage, tests, Nebr. 33.

fungi, bacteria, and nematodes of, collections, U.S.D.A. 636.

green, handling, 838.

grubs, pests in Tasmania, 513.

head smut and stripe smut of, seed treatment for control, U.S.D.A. 787.

head smut of, 493.

juice factor in legume silages and in milk produced therefrom, 375.

lawn, for South, 469.

marine, beach deposits, dog fly breeding in, U.S.D.A. 806.

Merker and Napier and crosses, reactions to *Helminthosporium* eye spot, 53.

native, reestablishing by hay method, Kans. 408.

native, sources of seed, comparison, Colo. 616.

native, v. bromegrass, palatability for sheep, Nebr. 33.

new, grazing tests, Tex. 181.

new, introduction, Tex. 181.

nutritive relations of boron to, 603.

oil-producing, notes, 164.

pasture, breeding, Ga.Coastal Plain 179.

pasture, studies, N.H. 317.

pasture, variety tests, Ga.Coastal Plain 179.

purple leaf blotch of, 792.

range, desert termite injury to, Tex. 214.

range, utilization, determining percentage, 468.

response to intensity of clipping, Nebr. 33.

root knot resistant and susceptible varieties, Ga.Coastal Plain 201.

## Grass(es)—Continued.

- roots, *Anguillulina robusta* and *A. obtusa* from, 203.
- roots, seasonal growth, 181.
- seed treatments with phytohormones and talc, effect, 40.
- semaphore, revision, 20.
- sickness in horses, relation to soil properties, 533.
- silage, *see* Silage.
- smut sori from ovarian and staminal tissues, 342.
- snow mold of, Minn. 792.
- southern, breeding for disease resistance, 317.
- southern, response to factors expressed by chart quadrat method, 317.
- summary, a memorial to J. H. Shepperd, N.Dak. 318.
- tall growing, management, for grazing, 225.
- transpiration rate, field method for estimating, 605.
- turf, improved, U.S.D.A. 771.
- variety tests, Tex. 180.
- vitamin content in different conditions, Nebr. 6.
- western, blotch and char spot of, 792.
- wild and cultivated, reactions to important rusts of United States and Canada, U.S.D.A. 52.

## Grasshopper(s)—

- bait, sawdusts in, 68.
- baits, studies, Ind. 65.
- clear-winged, poisoned baits for, 68.
- control, Nebr. 65.
- defoliation, damage to range forage by determination, Colo. 616.
- differential, development, relation to temperature, Nebr. 509.
- differential feeding on maturing wheat varieties, 216.
- effect on sagebrush in Wyoming and Montana, 509.
- lesser migratory, eggs, effect of tillage on, 64.
- lesser migratory, poisoned baits for, 68.
- plague in Spain, 352.
- problems in South Australia, 807.
- two-striped, poisoned baits for, 68.

Grassland(s)—*see also* Grass(es), Meadow(s), and Pasture(s).

- agriculture, U.S.D.A. 774.
- herbage, carotene content of species, 514.
- herbage, cystine and methionine in, 663.
- herbage, nutritional value, 81, 227.
- of Latin America, 616.
- Gravel-rock overfall structures, 837.
- Grazing—*see also* Range(s).
- and climate, U.S.D.A. 294.
- capacities, measurement, Colo. 616.
- crops, studies, Ga.Coastal Plain 225.
- on Welsh farms, cost, 402.
- Green bug, studies, Ga. 807.
- Green manure(s)—
- for cotton and other crops, Tex. 180.

## Green manure(s)—Continued.

- rotation and sequence experiments with, Tex. 180.
- sown in corn, effect on yields, Va. 616.
- Greenhouse—
- all-electric, construction, Wash. 691.
- leaf tier on artichoke, Calif. 507.
- thrips, laboratory control studies, 656.
- Greyhound bitches, effect of ovariectomy on racing performance, 315.
- Grouse—
- ruffed, *Leucocytozoon bonasae* in, 383.
- sage, susceptibility to strychnine, 806.
- Growth—
- constants, relative, validity of equations for, applied to sigmoid growth curves, 164.
- hormone, effect on mammary glands of hypophysectomized rats, 670.
- regulators, effectiveness of tryptophan mixtures as, 165.
- substances, *see* Plant growth substances.
- substances, synthetic, effect on transplants, 623.
- Grubs, white, *see* White grub.
- Gruidae, descriptive catalog, 351.
- Guajillo leaves, isolation of alkaloids from, Tex. 150.
- Guinea hen and fowl, reciprocal crosses, 767.
- Guinea pig(s)—
- inheritance of susceptibility to skin sensitization with chemical compounds, 28.
- pigment production in, genetic aspects, 612.
- spayed, inducing sexual receptivity in, 464.
- tissues, ascorbic acid deficiency and enzyme activity in, 872.
- Gull, California, and insect control in Utah, 64.
- Gypsum, effect on yields of peanuts, N.C. 34.
- Gypsy moth—
- economic injury to forest trees, 487.
- studies, Conn.[New Haven] 64, 65.
- Haemaphysalis humerosa*, biology, 214.
- Haematobia irritans*, *see* Horn flies.
- Haematopinus curysternus*, *see* Cattle louse, short-nosed.
- Haemonchus contortus*, *see* Stomach worm(s).
- Haemonchus* larvae, early losses after administration in susceptible sheep, 827.
- Hail damage in second-growth longleaf pine, 487.
- Hair, graying, effect of pantothenic acid, 424.
- Hairy root bacteria, crown gall bacteria, and radiobacter, comparative physiology, 338.
- Hairy vetch as green manure for cotton and other crops, Tex. 180.
- Halalophragmium ponderosum* on *Acacia leucophloea*, 802.
- Halicystis, membrane structure, X-ray observations, 167.
- Halticus citri*, *see* Flea hopper, garden.
- Ham, cured, salt and moisture in, determination, U.S.D.A. 602.

- Hare, snowshoe, new host of nematode parasites, 805.
- Harlequin bug, studies, Tex. 214.
- Harmolita tritici*, see Wheat jointworm.
- Hauposporium*—  
*diceracum* n.sp., notes, 62.  
*helicoideus* n.sp., notes, 62.  
*oajocotatum* n.sp., notes, 62.
- Harvesting machines, forage, new developments in, 397.
- Hay—  
acreages, production, price, etc., Del. 256.  
barn-dried, research on, 373.  
cost of production, Ind. 103.  
crops, variety tests, Miss. 407.  
cut v. whole for lambs, Ind. 76.  
feeding with pasture, 373.  
field curing methods, Miss. 101.  
grade, effect of cutting time and field method, Miss. 33.  
harvesting equipment, 838, Ind. 98.  
Johnson grass, v. sorghum silage, relative consumption by cows, Miss. 374.  
lands, permanent, maintenance, Vt. 318.  
meadows, fertilizer tests, Mont. 407.  
transportation, progress in, 838.  
yields in rotations, Minn. 773.
- Health—  
human, relation to brucellosis conquest in animals, 247.  
improvement for defense, station project, Colo. 699.  
in tropical climates, U.S.D.A. 294.  
practices and attitudes and related problems, Colo. 696.  
public, and veterinary research, 244.  
rural public, administration and finance in New York State, 119.
- Heart, extirpated, action of mallein on and nature of, 677.
- Heartworm, canine, treatment with fuadin and sulfanilamide, 383.
- Heat—see Temperature(s).
- Heating, work of Bureau of Agricultural Chemistry and Engineering on, relation to national defense, U.S.D.A. 835.
- Heifers—see also Cow(s).  
breeding efficiency, effect of subcutaneous administration of wheat-germ oil, Nebr. 80.  
chopped hegarl v. redtop fodder for, Tex. 225.  
dairy, metabolism rate at various ages, N.H. 374.  
dairy, protein requirements for growth, N.H. 374.  
mammary development as index of future producing ability, U.S.D.A. 819.  
menstruation frequency relation to conception in, 235.  
on summer pasture, effect of supplementary concentrate feeding, Ga. 820.
- Helenium* leaf spot, 789.
- Helminthidae, descriptive catalog, 351.
- Heliothis armigera* (*obsoleta*), see Bollworm, Corn earworm, and Tomato fruitworm.
- Heliothis assulta* in tobacco, life history, 75.
- Heliothrips haemorrhoidalis*, see Greenhouse thrips.
- Heltria picalta*, biology and control, U.S.D.A. 657.
- Helminth ova—  
and coccidial oocysts, simultaneous flotation, zinc sulfate v. sugar solutions for, 356.  
in horse feces, counting, method, 245.
- Helminthology, agricultural, manual, 804.
- Helminthosporium*—  
blight of corn, U.S.D.A. 201.  
leaf spot on millet, U.S.D.A. 336.  
*ravenelli*, notes, 490.  
*sacchari* on Napier grass, 642.  
*sacchari*, resistance of crosses of Merker and Napier grasses to, 53.  
spp. on sugarcane, 496.
- Helorimorpha* spp., parasites on *Antestia lineaticollis*, 514.
- Hemicelluloses, chemical studies, U.S.D.A. 723.
- Hemileia vastatrix* on coffee leaves, 60.
- Hemlock, western, causes of decay in, U.S.D.A. 788.
- Hemoglobin—  
and plasma protein, simultaneous production during continued bleeding, 704.  
regeneration in patients with vitamin C deficiency, 873.
- Hemoglobinometer, photoelectric, observations with, 724.
- Hemophilialike disease in swine, 683.
- Hemophilus gallinarum*, C factor requirement for growth, 254.
- Hemorrhagic—  
degeneration—  
evidence of deficiency of choline and of labile methyl supply, 275.  
in young rats, effect of cystine, fat, and cholesterol on, 274.  
in young rats, effect of diet constituents, 859.  
in young rats, interrelation of choline, cystine, and methionine in, 274.  
on low choline diet, relation to age, weight, and sex of young rats, 275.  
disease of newborn infant, vitamin K in, 714.  
septicemia, see Septicemia.
- Hemp—  
manila, see Abacá.  
plants, male and female, photosynthetic activity, 162.  
virus disease, 206.
- Hen(s)—  
accumulation of protein in oviduct, 666.  
inducing broodiness in small farm flocks, 225.  
laying—see also Egg production, antirachitic value of lamp radiation for, Nebr. 76.  
calcium metabolism in, 517.  
coarse mashers desirable for, Utah 232.  
fat absorption in, 517.

## Hen(s)—Continued.

- laying—continued.
  - green feed for, mustard, oats, and ryegrass as source, 372.
  - heat, ventilation, and humidity for, Ind. 76.
  - leg weakness in, on ascorbic acid-free diet, 666.
  - Sudan grass meal for, Nebr. 76.
  - manganese needs, Tex. 226.
  - molting, calcium and phosphorus metabolism in relation to chemical structure of bone, 518.
  - on low fat ration, absorption and retention of carotene and vitamin A by, 231.
  - spontaneous virilism of, ovarian tumors in, 31.

## Herb(s)—

- culture, Ga. 776.
- medicinal, N.H. 326.
- seeds, germination, N.Y.State 477.

## Heredity in livestock, Tex. 177.

## Heredity—

- of color, *see* Color inheritance.
- of eye anomaly in albino rat, 766.
- of hemophilialike abnormality in pigs, 765.
- of leaf variegation in beans, 764.
- of resistance to *Eimeria tenella* in poultry, 461.
- of resistance to physiologic races of bean rust, 493.
- of smooth and pitted bolls in Pima cotton, 763.
- of susceptibility to skin sensitization with chemical compounds, 28.
- of vaginal orifice shape in mice, 765.
- of watermelon seed characters, 459.
- studies in *Lycopersicum* crosses, 176, 177.

## Hermaphroditism—

- genetic, in strain of pigeons, 766.
- true, case in field mouse, 461.

## Hessian fly—

- control, Mo. 75.
- in Ohio wheatfields, Ohio 216.
- life history, habits, and control, Oreg. 75.
- studies, Ind. 65, Nebr. 65.

## Heterodera—

- marioni*, *see* Root knot nematode(s).
- schachtii*—

- cysts, recovery and counting, 62.
- races, specific status of, 62.
- unusual occurrences in Long Island potato field, U.S.D.A. 50.

*Heterodorus longitarsus* on dogs in Mississippi, 828.*Heterosporium* genus, studies, 490.

## Hewamita—

- meleagridis*—
- carriers of, 537.
- experimental infection of chicks with, 538.
- n.sp. from turkey, description, 254.
- [*muris*?] in blood of mouse, 828.
- Hexuronic acid, *see* Ascorbic acid.

Lickery leaves as indicators for trace elements, U.S.D.A. 740.

## Lides—

- disinfection, use of sodium bifluoride and sodium silicofluoride in, 249.
- research on, U.S.D.A. 723.

## Highway, Federal, new, program, 264.

## Hills, J. L., retirement, editorial, 433.

*Isotomonas* from wild pheasants and fowls, 828.

## Iog cholera—

- control, U.S.D.A. 676.
- immunity and pig anemia, 93.
- immunity and reticulo-endothelial system, 683.
- immunity studies, Nebr. 87.
- infected pigs, chemical changes in blood, 251.
- serum tests, Ind. 87.
- serum, value of closer supervision over distribution, U.S.D.A. 827.
- virus and similar biological products, value of closer supervision over distribution, U.S.D.A. 827.
- virus cultivation, 389.
- virus, in vitro neutralization with antiserum, 243.
- virus, lesions produced by, Ind. 87.

Hogs, *see* Pig(s) and Swine.

## Holly—

- American, *Fusarium* dieback of, U.S.D.A. 50.
- leaf miner, control, 812.

## Home decoration, handbook, 572.

## Home economics omnibus, revision, 700.

## Homonothermy, development in birds, 232.

## Honey—

- chemical studies, U.S.D.A. 723.
- of Ceylon, composition, 700.
- uptake of zinc during extraction from comb, 270.

## Honeydew melons, rotting in transit, prevention, Colo. 646.

## Honeydew records, 10-year summary, 364.

## Hookworm—

- and nodular worm infection in calves, blood picture, 388.
- immunity, quantitative relations, 828.

## Hop(s)—

- downy mildew control, rosin-potash spreader for spraying, Oreg. 346.
- improvement, U.S.D.A. 776.
- sooty mold control, N.Y.State 490.
- varieties and culture, N.Y.State 477.
- varieties best for New York, N.Y.State 191.

*Hoploplana inquilina thaisana* from mantle cavity of oyster drills, 806.*Hordeum murinum*, new host of *Puccinia anomala* in Uruguay, 490.*Horistonotus uhleri*, *see* Wireworm, sand.

## "Hormiguilla" control, effective poison bait for, P.R.U. 66.

## Hormones—

- gonadotropic, *see* Gonadotropic.
- plant, *see* Plant growth substances.
- role in development of higher plants, 452.

## Hormones—Continued.

sex, effect on proliferation and hydration of combs and cloacae of male chicks, 769.

studies, 123, 413.

Hornflies, abundance, seasonal occurrence and effect of host attractiveness, 512.

## Horse(s)—

abortion salmonellosis in, 677.

at work, energy expended by, N.H. 368.

bloat colic in, P.R.U. 87.

breeding, significance of hematological studies, 313.

diseases, control, U.S.D.A. 826.

diseases of newborn in, 243.

diseases, sulfanilamide for treatment, 390.

domesticated, stripings in, 610.

draft, effect of large doses of phenothiazine, 683.

feeding and measurements of production by, U.S.D.A. 662.

identification, new system for, 818.

internal parasites, Wis. 827.

meat for fur farms, composition, 79.

metabolism studies, N.H. 225.

nutrition of, 816.

Palomino color in, 313.

parasites and treatment for removal, U.S.D.A. 676.

parasites of, P.R.U. 382.

Percheron, gastrointestinal parasites, treatment, 390.

production, disease problems, 252.

removal of strongyles, phenothiazine for, 390.

saddle, problems in production, 225.

susceptibility to St. Louis encephalitis virus, 252.

## Horsefly(ies)—

mechanical transmission of anaplasmosis by, 89, Okla. 360.

Horse sickness vaccine, preservation with Merthiolate, 533.

Horticulture, early history in Oregon, 189.

## Hosiery—

wear position during Frazier test, 875.

women's, from commercial cotton yarns, properties, 571.

## House(s)—

condition of, of families on badly eroded soil, N.C. 104

farm, minimum requirements for, U.S.D.A. 430.

## Household—

equipment and housing, U.S.D.A. 716.

equipment studies, Ind. 142.

furnishings, making and buying, U.S.D.A. 714.

Humidity, new coefficient of, application to United States, 295.

Humin formation by acid hydrolysis of proteins, origin, Minn. 726.

Humus for Oregon soils, Oreg. 17.

Humus layers, forest, revised nomenclature, 298.

Hurricane San Felipe, changing intensity and rate of progress over Puerto Rico, 444.

Hybrid vigor in animals, physiological nature of, 28.

Hybridization—see also Animal breeding, Plant breeding, and specific animals and plants.

in violets, significance of chromosome number relations in, Vt. 312.

intergeneric, of cereals and grasses, 763.

Hydrocarbons and plant tissue, interaction, N.Y.State 454.

Hydrocyanic acid gas, behavior under fumigation tent, 656.

Hydrologic data of North Appalachian Experimental Watershed, Coshocton, Ohio, U.S.D.A. 444.

Hydrologic studies, U.S.D.A. 295.

Hydrophobia, see Rabies.

Hydroxyethylapocupreine dihydrochloride, new drug for treatment of bird malaria, 686.

Hygrometer as meteorological instrument, chemical absorption, 444.

*Hylemya (Hylomyia) brassicae*, see Cabbage maggot.

*Hylurgopinus rufipes*, see Elm bark beetle, native.

*Hypera brunneipennis* in Yuma Valley, Arizona, U.S.D.A. 363.

*Hyperdiplosis phloa* n.sp. from phlox, 512.

Hyperplasia, epithelial, in forestomach of rats, effect of choline, 556.

Hyperthyroidism, nitrogen metabolism in, 415.

Hypervitaminosis D in rats, toxicity, effect of renal damage, 566.

Hypervitaminosis of albino rats, calcium in soft tissues, 272.

Hyphomycete species parasitic on nematodes, 61.

Hypoglycemia, acute, in newly born pigs, 832.

Hypophysectomy and replacement therapy, effect on thyroid and adrenal glands of male squirrel, 466.

Hypophysis, see Pituitary.

*Iatrophobia brasiliensis*, notes, 221.

## Ice cream—

and ices, use of corn sirup solids in, 382.

body, texture, and quality, factors affecting, Ind. 80.

chocolate coating for, viscosity and coverage value, 382.

color in, selection and use, 526.

control of whipping in, temperature method, 526.

corn sweeteners for, 525.

fat in, determination methods, Nebr. 80.

frozen, injection of fruit and sirups in, 382.

mix, vaccination of, 382.

production, increasing amount per kilowatts consumed, 382.

sandiness in, causes and control, 526.

sanitary control, report on, 87.

## Ice cream—Continued.

stability and melt-down properties, motion pictures for showing effect of factors on, 382.

use of corn sirup in, Wis. 820.

*Icerya purchasi*, see Cottony-cushion scale.

Ices and sherbets, corn sweeteners for, 525.

Illinois Station, notes, 431.

Illinois University, notes, 481.

Immunity acquired, use of term, 337.

Incubation of eggs at high altitude, 232.

Incubators, small, temperature and humidity regulation in, U.S.D.A. 214.

## Index numbers—

of prices farmers pay, appraisal, 548.

of production, prices, and income, Ohio 104, 282, 540.

## Indexes—

of prices received and prices paid by farmers, Del. 256.

on a type-farm basis, 401.

Indiana Station, notes, 573.

Indiana Station, report, 143.

*Indigofera endecaphylla*, toxicity for rabbits, 535.

Industrial map, changing, U.S.D.A. 852.

## Infant(s)—

coccarboxylase in blood of, 860.

homogenized vegetables in diet of, 701.

newborn, prothrombin in, relation to maternal vitamin K intake, 280.

newborn, vitamin K in hemorrhagic disease of, 714.

vitamin B<sub>1</sub> requirement, determination, 710.

Infantile paralysis, see Poliomyelitis.

## Influenza—

A virus, mica immune to, strain specificity of complement fixation with sera of, 245.

swine, epidemiologic pattern, effect of host and intermediate reservoir host, 520.

Inheritance, see Heredity.

## Insect(s)—see also Entomology.

and weather, U.S.D.A. 204.

as carriers of poliomyelitis virus, 807.

bacteria associated with, 506.

beneficial, peculiar habits of, 216.

biological control, 215.

collecting large numbers from host plants, scoop for, U.S.D.A. 214.

common names, 214.

control from the air, 352.

development, endocrine control of, 651.

economic, of Scotland, 353.

estimating population over areas of many square miles, 214.

important nursery, of New Jersey, 353.

in Siam and Indo-China, 353.

infesting stored food products, methods used in rearing, 507.

injurious to crops, see *special crops*.

leaf-eating, sulfur as insecticide for, 353.

military importance of war on, U.S.D.A. 806.

of Puerto Rico, supplement, P.R.U. 214.

## Insect(s)—Continued.

on nursery plants, dormant treatments for, N.Y.State 651.

orchard, see Orchard insects and Fruit insects.

parasites, effects of hosts on, 508.

pest record for Oklahoma, 506.

pests, control, Miss. 572.

pests in stored products, 216.

pests of economic crops in Uruguay, 637.

pests, studies, Tex. 214.

 Newcastle disease, immunization experiments, 247.  
*Necara viridula*, see Stinkbug, southern green.  
*Nicotiana*—  
   *rustica* interspecific hybrids, increased size and nicotine in, 458.  
   *tabacum*, haploids in, production by X-rays, 763.  
 Nicotinamide—  
   physiological activity and clinical use, 134.  
   urinary excretion by normal adults, 134.  
 Nicotine sprays, types, characteristics, 354.  
 Nicotinic acid—  
   and its derivatives, urinary excretion by normal adults, 134.  
   bibliography, 423.  
   concentration and distribution in blood, 134.  
   deficiency, effect on coenzyme I content of human erythrocyte and muscle, 423.

## Nicotinic acid—Continued.

deficiency in silver foxes and minks, U.S.D.A. 676.

derivatives in human urine, 712.

determination, decolorization of acid digestion mixtures for, 442.

determination, inhibitory effect of cyanogen bromide on aniline side reactions, 11.

excretion by rabbits, relation to intake, 227.

in blood, 868.

in blood and urine, determination, clinical method, 735.

physiological activity and clinical use, 134.

polarographic determination, 10.

values, urinary, effect of excretion of other pyridine compounds, 11.

## Nitrate stabilization in soil samples, 596.

## Nitrification, effect of—

chemicals and vitamin B<sub>1</sub>, Tex. 157.

phosphatic and potassic fertilizers, Ind. 16.

## Nitrogen—

ammonia forms, studies on nitrogen-deficient soils, Ind. 16.

economy of Australian wheat soils, 160.

fertilizers, 40 years' results from, 299.

## fixation—

biochemical, 453.

by soybeans under different potassium levels, Mo. 18.

effect of minor elements, U.S.D.A. 740.

nonsymbiotic, in semiarid soils of north China, 596.

symbiotic, effect of mineral fertilizers, Ind. 16.

symbiotic, mechanism, nature of inhibition by hydrogen, 601.

fixing and cellulose-decomposing bacteria, association between, 762.

isotopic studies, Conn. [New Haven] 6.

oxides, removal in semimicrodetermination of carbon and hydrogen, 728.

residual effect of, Ga. 741.

sources, equivalent acidity or basicity of, Ga. 741.

sources on very acid Cecil sandy loam, Ga. 741.

## Nitrogenous fertilizers, effect on composition and yield of pasture plants, Va. 748.

*Nitzschia*—

*closterium*, carotenoid-sensitized photosynthesis in, evidence for, 167.

*palea debilis*, p-aminobenzoic acid an essential metabolite for, 608.

## Nodular worms—

of cattle, blood picture, 388.

of cattle, life history, P.R.U. 90.

of sheep, phenothiazine for control, 389.

## Nodule bacteria—

and *Azotobacter*, similarity of N-fixing systems of, Wis. 774.

and legumes, symbiosis, 302.

competition between related strains, 302.

## Nodule bacteria—Continued.

mutability, 752.

of legumes, 752.

relation to host cells, effect of boron, 646.

Nodules of legume roots, respiration of, 758.

Normal and median, use of terms, 836.

North Carolina College, notes, 575.

North Carolina Station, notes, 575, 878.

North Carolina Station, reports, 143.

North Dakota College, notes, 575.

North Dakota Station, notes, 575.

*Nosopsyllus fasciatus*, see Rat flea.

Nucleohistone from mammalian organs, preparation and origin, 765.

*Nummularia* spp., taxonomic study, 450.

## Nursery (ies)—

eradicating root rot in, Tex. 201.

inspection, Conn. [New Haven] 64.

site, selection and preparation, U.S.D.A. 197.

stock studies, U.S.D.A. 198.

## Nut (s)—

climatic adaptation, U.S.D.A. 294.

diseases important in Virginia, 503.

fertilizer tests, Tex. 189.

growing in South Dakota, questions and answers on, S.Dak. 43.

insects, studies, Tex. 213.

production, long-term forecasting, 401.

propagation and breeding, Tex. 189.

species, native, N.H. 335.

variety tests, Tex. 189.

## Nutgrass—

control by cultivation and chemicals, Miss. 467.

life history and control, Ala. 616.

## Nutrient—

media, see Culture media.

solution, control of pH and nitrate levels in by nitric acid, 757.

## Nutrition—

and dental caries in London elementary school children, 833.

and food, laboratory and business relation in, 550.

and food, needed research in, 550.

and food studies, Ga. 854.

animal, see Animal nutrition.

campaign for present emergency, U.S.D.A. 854.

Canadian, 123.

human, mass studies in, hemoglobin values, 557.

in defense, 554.

knowledge, progress of, U.S.D.A. 854.

level, assessment of, 711.

outlook, national, 555.

plant, see Plant nutrition.

program work, 414.

studies, 413.

vitamin A in, U.S.D.A. 700.

## Nylon—

qualitative identification and quantitative estimation, in presence of silk, wool, and cotton, 281.

textile fibers, identification, 281.

*Nysius ericae*, see Chinch bug, false.

# Oak—

- diseases and other disturbances, 802.
- diseases in Illinois, 803.
- flooring, *Coprinus micaceus* growing on, 790.
- pin, growth following transplanting and pruning, 634.
- posts, preserving, Conn.[New Haven], 49.
- red, response to ammonium sulfate fertilization, 634.

Oak-pine rust, distribution and suggested control, U.S.D.A. 650.

# Oat(s)—

- breeding, Ga. 772, Ga.Coastal Plain 179, N.C. 34, Nebr. 33, Tex. 180, U.S.D.A. 771.
- crop increase, dairymen's interest in program, Miss. 467.
- crop, program to increase, of interest to dairymen, Miss. 572.
- culture experiments, Ga.Coastal Plain, 179, Miss. 772.
- effects of clipping, La. 32.
- fertilizer formulas and rates of application, Ga.Coastal Plain 179.
- fertilizer tests, Ga. 772, Miss. 772, Tex 180.
- flour-treated milk bottles for milk exposed to sunlight, 825.
- grazing, value for laying hens, 372.
- hardy winter, disease resistance, U.S.D.A. 771.
- in rotation, sweetclover as intercrop, Ind. 32.
- loose smut, susceptibility of Lee × Victoria selections, 640.
- loose smut, testing fungicides against, 640.
- N for, sources, rate, and date of applying, Miss. 317.
- N sources for side dressing, La. 33.
- proteins, biological values, 226.
- rod row plat tests, effect of different distances apart, 35.
- seed germination after eight years, N.Y.State, 187.
- seed treatment, Tex. 202.
- seeding rates and dates, Miss. 33.
- smuts, loose and covered, inheritance of resistance to, in hybrids, 789.
- smuts, physiologic races, 789.
- stem rust, oversummering on orchard grass, U.S.D.A. 336.
- varieties and strains, registration, 183.
- varieties for hills and Delta, Miss. 33.
- varieties, spring, for Illinois, Ill. 774.
- varieties, winterhardiness tests, Tex. 180, U.S.D.A. 618.
- variety tests, Ga. 772, Ga.Coastal Plain 179, La. 32, Miss. 33, 467, 772, N.C. 34, Nebr. 33, Tex. 180.
- variety yield differences, factors affecting, N. Dak. 640.

# Oat(s)—Continued.

## yield(s)—

- effect of sorghum stubble or stalk on, Tex. 180.
- good, relation to good seed planting, Miss. 467.
- in rotations, Minn. 773.
- increase by legumes, Miss. 33.
- of different crops after, Miss. 772.

*Oboliscoides cuniculi* in woodchuck, 805.

*Ocotea barcellensis*, notes, 752.

*Oeciacus vicarius*, see Swallow bug.

Oecophoridae, revision, with descriptions of new genera and species, 511.

Oesophagostomiasis in cattle, clinical aspects, 827.

# Oesophagostomum—

*columbianum* in sheep, factors causing death in, 251.

*columbianum* in sheep, phenothiazine for control, 389.

*radiatum*, life history, P.R.U. 90.

Oestradiol or oestradiol benzoate in castrate female rats, inactivation, 30.

# Oestrogen—

effect on mammary glands of hypophysectomized rats, 670.

injected into hypophysectomized female rats, effect on mating behavior, 465.

sensitivity to in female guinea pig and rat, 612.

# Oestrone—

effect on sexual receptivity in spayed guinea pigs, 464.

inactivation by liver, prevention by vitamin B complex-deficient diets, 316.

# Oestrus—

and ovulation in rat, 618.

irregular or absent in rats, 770.

ovulation, and related phenomena in mare, Mo. 178.

# Office of—

Experiment Stations, notes, 144.

Foreign Agricultural Relations, report, 876.

Ohio State University, notes, 431.

Ohio Station, notes, 431, 575, 720.

*Oidaematophorus* spp. on artichoke, Calif. 507.

Oil(s)—see also Fat(s) and specific oils.

associations, cooperative, in Nebraska, Nebr. 111.

atomized, toxicity tests on scale insects, Tex. 214.

chemical composition affecting efficiency, N.Y.State 653.

chemical studies, U.S.D.A. 723.

for rats, nutritive value, U.S.D.A. 662.

iodized mineral for bovine mastitis, 531.

## spray(s)—

and emulsions, advances in chemistry and physics of, 653.

deposits, methods of measuring, 653.

effects on deciduous trees, 654.

increasing effectiveness in citrus

pest control, 655.

petroleum, physiological effects on citrus, 654.

## Oil(s)—Continued.

## spray(s)—continued.

petroleum, toxicants used with on deciduous fruits, 655.

tocopherol in, determination, 413.

vegetable, in ration, effect on weight and quality of egg yolks, 372.

vegetable v. mineral, insecticidal efficiency, U.S.D.A. 807.

Oklahoma College, notes, 432, 575.

Oklahoma Station, notes, 432, 575, 878.

Okra breeding, Tex. 189.

Oleanders, breeding, Tex. 189.

Olive fruitfly, attractants for, 352.

Olive insects in Spain, 352.

*Oncopera* spp., pasture pests in Tasmania, 513.

## Onion(s)—

bloat due to *Ditylenchus dipsaci*, 490.

breeding and fertilization, Colo. 623.

bulb epidermis, electrolytes and nuclear structure of cells, 168.

diseases, control, 494.

market diseases of, U.S.D.A. 796.

molds in markets, 639.

pink root, host-parasite relations, 208.

pink root resistance, breeding for, Tex. 202.

root, water balance in, 605.

snout control, 647.

Texas species, description and notes, 301.

thrips control, Conn.[New Haven] 65.

thrips-resistant varieties, P.R.U. 42.

thrips, studies, Tex. 214.

varieties, American, storage quality, U.S. D.A. 478.

varieties, principal American types, descriptions, U.S.D.A. 191.

yellow dwarf, control, Oreg. 343.

*Oosporea lactis*, phosphatase production by, 85.

*Ophiobolus graminis*—

growth factor requirements, 793.

in soil, factors, affecting, 640.

## Ophthalmia, periodic—

relation to brucellosis, 528.

studies, U.S.D.A. 676.

## Orange(s)—

composition, effects of oil spray v. hydrocyanic acid fumigation, 655.

Florida and California, frost damage relation to juice content, 736.

Florida-grown, carotenoid pigments in juice, 333.

fruit scab, control in Argentina, 648.

grove, fertilizer experiments in, 784.

Pineapple, spraying experiment with naphthalene, 477.

riboflavin content, 869.

trees, pruning for leprosis control, 648.

trees, young, transpiration rate, effect of soil temperature, 106.

## Valencia—

alternate bearing and fruit size, effect of time and amount of harvesting, 196.

anatomy of seedling and roots, U.S.D.A. 607.

manganese deficiency in, 485.

Orchard(s)—*see also* Fruit(s), Apple(s), Peach(es), *etc.*

calyx sprays, hours of labor and gallons of spray per mature trees, N.H. 401.

cultural systems, soil organic matter and available moisture under, 626.

diseases, in eastern New York, control, 647.

eradication root rot in, Tex. 201.

erosion control, U.S.D.A. 480.

grass, breeding, 175, U.S.D.A. 771.

grass, cystine and methionine in, 664.

grass, nutritive value, rat tests of, U.S.D.A. 662.

grass, winterhardiness and rust reaction of parents and inbred progenies, 173.

infiltration rates, effect of soil management on properties in relation to, 626.

insects, in eastern New York, control, 647.

management, Ind. 41.

Missouri, damage from Armistice Day freeze, 740.

## soil(s)—

effect of mulch on exchangeable potassium in, 300.

fertilizer needs, methods of study, 299.

maintenance and improvement of fertility in, 480.

management, effects, 743.

nitrate content, factors affecting, 743.

of New York, available potassium in, 480.

oxygen and carbon-dioxide levels, seasonal and soil effects, [N.Y.] Cornell 297.

studies, Conn.[New Haven] 16.

treatment experiments, 330.

spraying for insects, Nebr. 42.

sprays, petroleum oils for, new basis for selecting, N.Y. State 652.

winter and early spring care, Miss. 779.

## Orchid(s)—

bug on white mariposa, 510.

use of fungicides on, 801.

## Organic matter—

conceptions and misconceptions, 448.

decomposition, soil respiration studies on, 150.

of soil, Nebr. 16.

value to soils, N.C. 16.

Organisms—*see also* Bacteria and Micro-organism(s).

autotrophic, *p*-aminobenzoic acid an essential metabolite for, 603.

Ornamental plants, shrubs, and trees, *see* Plant(s), Shrubs, and Tree(s).*Ornithodoros*—

*hermsi* and relapsing fever in Oregon, 365.

*parkeri* and relapsing fever spirochetes in Utah, 815.

*parkeri*, biology, 365.

- Ornithodoros*—Continued.

  - improvement with triple superphosphate, effect on soil and water losses, Va. 746.
  - in Mississippi, Miss. 33.
  - management, [N.Y.]Cornell, 447, 468, Tex. 181, Vt. 318.
  - measuring with dairy cattle, 317.
  - mixtures, botanical and yield study, 468.
  - plants, composition and yield, effect of nitrogenous fertilizers, Va. 748.
  - production, effect of soil type and chemical composition, Va. 742.
  - research technics, 317.
  - studies, 10, 317, [Conn.]Storrs 319, Ga. 772, Ga.Coastal Plain 225, Miss. 34, 467, 772, N.C. 34.
  - tame, in Kansas, Kans. 468.
  - turf samples in England, *Anguillulina erythrinae* from, 203.
  - weeds, control, ex. 181.
- Pea(s)—
- Aphanomyces* root rot, factors affecting, 208.
- Pea(s)—Continued.
- aphid—
- as factor in growing peas on Long Island, N.Y.State 652.
  - color preference in western Oregon, 64.
  - control, 69.
  - control, concentrated sprays for, N.Y.State 651.
  - new parasite from, 813.
  - stock, uniform, technic in producing, U.S.D.A. 214.
- Austrian Winter, diseases, breeding and selection, Ga. 789.
- breeding, Tex. 189.
- canning byproducts, nutritive value and composition, 816.
- cuprous oxide as seed protectant for, 647.
- English, fertilizer treatment for, Miss. 478.
- English garden, diseases, breeding and selection, Ga. 789.
- English, varieties, comparative cold resistance, Ala. 623.
- English, variety, breeding, and fertilizer tests, Miss. 776.
- fertilizer placement for, N.Y.State 477.
- foot rot and root rot, N.Y.State 490.
- frozen, determining maturity, 734.
- leaf spot caused by *Cercospora lathyrina*, 346.
- market diseases of, U.S.D.A. 796.
- nodulation and dry weight, effect of sulfur and sulfates, 779.
- response to seed treatments with hormones and mercurials, 622.
- compatibility of *Spergon* and *Rhizobium leguminosarum* on, 309.
- production, effect of *Rhizobium leguminosarum* and of gypsum and straw, 159.
- treatment, N.Y.State 490.
- stand and yield, effect of seed treatment, 797.
- varietal resistance to *Septoria pisi*, 647.
- varieties with pods resistant to *Ascochyta pisi*, 346.
- variety tests, N.Y.State 477.
- virus 2, isometric crystals produced by, 58.
- yield doubled by seed treatment, Miss. 847.
- Peach(es)—
- aphid, green, cause of virosislike injury of snapdragon, 649.
- aphid, green, control on Long Island, 510.
- borer control, N.C. 65, N.Y.State 220.
- borer control, new methods for, 507.
- brown rot, control, N.Y.State 490.
- breeding, Tex. 189.
- buckskin disease, 210.
- buds, breaking rest period of, test of sprays for, 47.
- disease, line pattern transmitted from Abundance plums, 348.

## Peach(es)—Continued.

- disease, new so-called virus, in Washington, 500.
- effect of carbon dioxide in transportation and storage, 195.
- Elberta, extent of colored area, relation to leaf area, 782.
- factors affecting longevity, Ga. 776.
- fertilization, recent research, 326.
- fertilizers for, Miss. 477.
- fruit thinning and pruning, 326.
- insects in South, control, 216.
- leaf curl fungus, diurnal cycle of ascus maturation, 59.
- leaves, effect of soil treatment on N, P, and K values, 627.
- leaves, potassium content, survey, 46.
- marginal leaf spot transmission, U.S.D.A. 336.
- mosaic eradication, U.S.D.A. 336.
- mosaic, insect transmission, Colo. 651.
- mosaic studies, Colo. 636.
- orchards, cover crops for, Ga. 776.
- orchards, failure due to nematode attack, 211.
- peeling, Ga. 723.
- Percgrine, wooliness, relation to final ripening period, 194.
- Phillips Cling, embryo abortion in, mathematical model of, 799.
- planting, cultivation, and cover crop practices, 326.
- potash requirements, U.S.D.A. 776.
- pruning, Miss. 477.
- ring-spot virosis, 200.
- root knot, effect of cover crops, Ga.Coastal Plain 201.
- root knot-resistant rootstocks, Ga.Coastal Plain 201.
- roots, growth, Ga. 776.
- roots, potassium translocation in, 484.
- roots, toxicity, relation to reestablishing peach orchards, 46.
- rootstocks, development from domestic sources, U.S.D.A. 776.
- rootstocks, nematode-resistant, N.C. 42.
- seed treatment affecting germination and growth of seedlings in greenhouse, 483.
- seedlings, cross-bred, inheritance in, 27.
- seedlings, failure to respond to vitamin B<sub>1</sub>, 43.
- stem canker in Buenos Aires, 500.
- storage studies, Ga. 723.
- strains showing high tolerance to standing or undrained water, 210.
- summer sprays for, Tex. 202.
- susceptibility to bacterial fruit and leaf spot diseases, relation to nutrient deficiency, N.C. 42.
- systemic arsenic toxicity on old apple land, U.S.D.A. 636.
- tetraploidy in, colchicine-induced, 764.
- thinning, time of, 332.
- tree winter injury, 647.
- trees and crabgrass, competition between for soil moisture, N.C. 42.

## Peach(es)—Continued.

- trees in Sandhills, nitrogen requirements, 325.
- types, behavior and value in crossing, 332.
- use of hormone sprays on, N.H. 326.
- varieties, Ga.Coastal Plain 188.
- varieties in Arkansas, Ark. 46.
- varieties, new, for trial planting, Miss. 46.
- varieties, yields, Miss. 776.
- variety tests, Ga. 776, Ind. 41.
- viroses, studies, 200.
- virus diseases in western Colorado, U.S.D.A. 336.
- virus diseases, symptoms and control, N.J. 799.
- X-disease—
  - clinic, success of, U.S.D.A. 201.
  - control, 490.
  - in Michigan, U.S.D.A. 50.
  - in Pennsylvania, U.S.D.A. 201.
  - malady resembling, 200.
  - studies, Conn.[New Haven] 51, U.S.D.A. 788.
  - western, transmission, U.S.D.A. 336.
- yellow-red virosis, see Peach X-disease.
- yellow, active spread in northern Virginia, U.S.D.A. 50.
- Peanut(s)—
  - and peanut products, marketing, U.S.D.A. 546.
  - black spot, varietal susceptibility, 56.
  - breeding, Ga. 772, Ga.Coastal Plain 179, N.C. 34, Tex. 180, U.S.D.A. 771.
  - Cercospora* leaf spots, 489.
  - culture experiments, Ga.Coastal Plain 179.
- disease(s)—
  - apparently undescribed, 206.
  - in Jamaica, 789.
  - in Texas, U.S.D.A. 636.
- fertilizer formulas and rates of application, Ga.Coastal Plain 179.
- fertilizer tests, 317, Ga. 772, N.C. 37.
- humus v. agar cultures for nodule bacteria, 451.
- index of nutrient levels for, 317.
- leaf spot control, Ga. 789, N.C. 51.
- leaf spot, sulfur dust for control, Ga. Coastal Plain 201.
- litter, dog fly breeding in, U.S.D.A. 806.
- meal and soybean meal v. trinity mixture for pigs, U.S.D.A. 662.
- oils, insecticidal efficiency, U.S.D.A. 807.
- plant, mineral nutrient extraction and distribution in, 473.
- planting test, P.R.U. 34.
- pouts, causes, 336, 352, 357.
- processing, Ga. 723.
- production practices, Ga. 472.
- response to day length, effect of illumination intensity, 775.
- response to day length, effect of temperature, 775.
- rust, notes, U.S.D.A. 636.
- seed, treatment for, Ga. 772.

## Peanut(s)—Continued.

- seedlings, thrips injury, U.S.D.A. 336, 357.
- studies in field plat technic, 317.
- varieties, oil-yield tests, P.R.U. 6.
- varieties, response to fertility levels, 317.
- variety tests, Ga. 772, Ga.Coastal Plain 170, N.C. 34, P.R.U. 34.
- Virginia type, improvement, 317.
- yields, effect of specific fertilizers, N.C. 34.

## Pear(s)—

- and other plants, incompatibility, physiology, 42.
- Bartlett, changes in vitamin C content in cold and gas storage, 566.
- blight-resistant, development, N.Y. State 477.
- blight studies, U.S.D.A. 336.
- harvest maturity, index of, 194.
- polyploidy in, induction, 42.
- riboflavin content, 869.
- scab control and spray injury, 200.
- seedless, production, 42.
- seedlings, failure to respond to vitamin B<sub>1</sub>, 43.
- stock and scion studies, Ind. 42.
- varieties, Ga.Coastal Plain 198, Ind. 42
- varieties, yields, Miss. 776.
- waxing experiments, 44.

Peat litter for poultry, moisture in, N.H. 360.

## Pecan—

- borer on top-worked pecan trees, control, 70.
- leaves in fall, effect of downy spot on photosynthesis and transpiration, 503.
- nutrition, boron in, 334.
- scab control, U.S.D.A. 788.
- seedling growth, response to boron, 326, 489.
- shellers of San Antonio, 698.
- stem tissue, rooting by layering, 326, 333
- trees, fertilization, U.S.D.A. 770.
- trees, top-worked, control of borers on, 70.
- twigs, dormant, nitrogen content, 333.
- varieties, Ga.Coastal Plain 188.

## Pectin—

- sterilization, chemical method, 170.
- studies, N.Y.State 435.

*Pectinophora gossypiella*, see Bollworm, pink.

*Peponomyia* genus, revision of North American species, 222.

*Pempherulus affinis*, biology under controlled conditions, 219.

*Penicillium*—

*cytopium*, notes, 802.

*thomii* on *Cypridium*, 789.

Pennsylvania College, notes, 575, 720.

Pennsylvania Station, notes, 575, 720.

Peony blight, varietal resistance, N.H. 337.

## Pepper(s)—

- ascorbic acid content, 135.
- mosaic limiting expansion of this crop. P.R.U. 51.
- natural crossing in, 625.

## Pepper(s)—Continued.

## pimiento—

- analyses, Ga. 723.
- better methods of production, Ga. 479.
- diseases in Jamaica, 789.
- use of starter solutions for, Ga. 776.
- resistance to *Scelerothium rolfsii*, (Ga. 789).
- root rot caused by *Phytophthora capsici*, 347.
- virus infected perennial, mosaic, chlorosis, and necrosis in, 495.
- wilt control in Mendoza, Argentina, 797.

## Peppermint—

- anthracnose control, spraying and depth of plowing in, Ind. 51.
- oil, composition, variation during distillation, Ind. 6.

Pepsin, effect of high pressure on activity, 436.

Percolator, improved automatic continuous, 723.

*Pericgrinus maidis*, vector of corn mosaic, incubation period and longevity of virus in, 809.

*Peridermium strobi*, see White pine blister rust.

*Periplaneta americana*, see Cockroach, American.

*Pterilopis globiventris*—

- host plant record for, 64.
- on artichoke, Calif. 507.

*Perognathus* spp., animal reservoirs of, 828.

*Peromyscus*—

- cremicus*, animal reservoirs of, 828.

gene interaction in, 765.

*Peronoplasmodium cubensis*, protection against, 200.

*Peronospora*—

- manshurica* notes, U.S.D.A. 788.

*aphaciaceae*, studies, 489.

## Perosis—

- effects of iron salts on, Colo. 676.
- in chicks, prevention by a combination of nutrients, 834.
- relation to choline and other dietary supplements, 538.

Persimmon, Hachiya, starch cycle in, 784.

Pest control equipment, U.S.D.A. 835.

*Pestalotia molleri*, notes, 490.

## Petroleum oil(s)—

- as insecticides, 355, N.Y.State 215.
- solubilizers for, 654.
- sprays, physiological effects on citrus, 654.
- sprays, toxicants used with on deciduous fruits, 655.

Pheasants, color inheritance, 462.

*Phellinus cryptarum* relation to destruction of wood by death-watch beetle, 659.

Phenology, literature of, summary, 740

Phenols, 2,4-dinitro-6-R-, relative toxicity, 354.

## Phenothiazine—

- and related substances as anthelmintics, 383.

## Phenothiazine—Continued.

- as anthelmintic, 246, 250, U.S.D.A. 676.
- as anthelmintic in goats, limited tests, 827.
- controlled experiment with sheep, 532.
- effect of repeated doses on sheep, 682.
- effect on hemoglobin concentration, erythrocyte, and leucocyte count of swine, 833.
- effect on horses, 253.
- effectiveness against internal parasites, U.S.D.A. 826.
- experiment statistically treated, 532.
- failure against *Strongyloides papillosus* in lambs, 532.
- large doses, effect on draft horses, 683.
- prepared with allotropic forms of sulfur, toxicity to codling moth, 352.
- studies, 678.
- test, on fattening lambs, 251.
- v. copper sulfate-nicotine sulfate mixture as anthelmintics for sheep, 251.
- Philodendron* cuttings, abnormal rooting, calcium deficiency as factor, 60, N.J. 801.
- Phleum pratense*, *P. subulatum*, and their F<sub>1</sub> hybrid, melotic behavior, 457.
- Phlyctaena* new species, 789.
- Phlyctaenella rubigalis*, see Greenhouse leaf tier.
- Pholiota adiposa*, growth rate, 61.
- Phoma*—
  - citricarpa*, cuprous oxide mixture for control on citrus, 648.
  - persicae* studies, 500.
  - terrestrial action on onion and other hosts, 203.
  - terrestris* pigment, 636.
- Phomopsis vexans* on eggplant, resistance studies, 494.
- Phoradendron* to *Picea*, host-parasite checklist revision, U.S.D.A. 336.
- Phormia regina* during metamorphosis, interconversion of food in, 811.
- Phosphatase—
  - production in dairy products by microorganisms, 85.
  - serum, of cattle and sheep, 821.
  - test, application to special types of milk, 86.
- Phosphate(s)—
  - applied in narrow bands for beetler results, Miss. 749.
  - colorimetric determination, 585.
  - comparison for crop production, Ala. 593.
  - deficient diet, growth and calcification on, 703.
  - domestic mineral, arsenic in, U.S.D.A. 597.
  - fertilizer, production, U.S.D.A. 740.
  - fertilizers, comparison, N.C. 16.
  - in soil extracts, determination, methods, 732.
  - organic and inorganic, comparative availabilities, 597.
  - rock, availability, effect of ammonium sulfate, Ala. 593.
  - soluble organic, added to soils, behavior, 597.

- Phospholipids as a source of energy for motility of bull spermatozoa, 768.
- Phosphoric acid esters related to phosphatides, synthesis, 436.
- Phosphorus—
  - and calcium metabolism, effect of fat, 558.
  - and calcium metabolism, phases of study, Conn. [New Haven] 123.
  - and calcium metabolism, studies, 272.
  - availability in phosphate fertilizers, Ky. 19.
  - compounds in milk powders, 86.
  - fixation by soil separates and fractions, 749.
  - fixation, relation to iron and aluminum of soil, 749.
  - fixation studies by use of radioactive isotope, 749.
  - in soil and plant material, determination, 154.
  - indigenous in acid tropical soil, 209.
  - metabolic behavior, 705.
  - organic, in lake waters, perchloric acid oxidation, 729.
  - radioactive, soil studies with, 300.
  - sources for bone calcification, 125.
  - sources of, Ga. 741.
- Photometer and its accessories, improvements in, 413.
- Photoperiodism, trends in studies of future investigation, 759.
- Photosynthesis—
  - and transpiration, method for studying simultaneously, 162.
  - automatic conductivity system for measuring, 760.
  - device for measuring rate in plants, 760.
  - energy of, effect of water content and carbohydrate accumulation, 162.
  - in monochromatized light, Ind. 6.
  - in plants at high altitudes, 760.
  - increasing rate by spraying with microelements, 453.
  - of apple leaves, effect of soil moisture, 320.
  - of apple leaves, effect of sulfur fungicides on, 489.
  - of apple trees, effect of oxygen and carbon dioxide in soil atmosphere, 482.
  - of pecan leaves, effect of downy spot, 503.
  - photochemical and dark reactions in, effect of hydration degree of assimilatory tissue, 162.
  - treatise, 605.
  - with radioactive carbon and distribution of photosynthetic products, 760.
- Phthalonitrile as insecticide, U.S.D.A. 806.
- Phthorimaea heliopa*, notes, 75.
- Phycomyces*, thiazole effect on, 452.
- Phyllachora fuscarpa* in Florida, U.S.D.A. 788.
- Phyllocoptes oleivorus*, see Citrus rust mite.
- Phyllophaga tristis* and allied forms, life history, 70.
- Phyllosticta*—
  - antirrhini*, notes, 789.

*Phyllosticta*—Continued.

new species, 789.

*solitaria* survival in New York, U.S.D.A. 201.

Phyllotaxy of tobacco, 760.

*Phyllotreta vittata discors*, studies, 71, Tex. 214.

*Phymata pennsylvanica americana*, quantitative dietary studies, 357.

*Phymatcus leprosus* in Eastern Cape Province, 69.

*Phymatotrichum omnivorum*—

carbon utilization and carbohydrase activity, 343.

root rot, control, N.Mex. 203.

studies, Tex. 201.

toxicity of alkaloids of Amaryllidaceae to, 793.

*Physalospora*—

*malorum*, notes, 490.

*niyabeana*, notes, 351.

Physiology, annual review, 856.

Physiology, developmental, 123.

## Phytogeography of—

Argentina, principal features, 751.

Peru, 752.

Phytohormone activity, determination, new method, 452.

*Phytomonas*—

*angulata*, notes, 208.

*polycolor*, virulence to small laboratory animals, 796.

*scopodonia* infection of potato by cutting knife, control with iodine, 344.

*scopodonia*, notes, 794.

*solanacearum* on tomato, P.R.U. 51.

spp., production of gluconic acid and 2-ketogluconic acid from glucose by, 309.

*tabaci*, notes, 208.

*tumefaciens*, *P. rhizogenes*, and *Alcaligenes radiobacter*, comparative physiology, 338.

*vesicatoria* spot infection on tomatoes, source of, Ind. 51.

*Phytomyza*—

*atricornis* on artichoke, Calif. 507.

*ilicis*, see Holly leaf miner.

*Phytophaga destructor*, see Hessian fly.*Phytophthora*—

bleeding canker of *Quercus agrifolia*, 200.

*boehmeriae*, notes, 501.

*cactorum* antidoting toxin for plant disease control, 649.

*cactorum* on maple, 649.

*capsici* on pepper and pumpkin, 347.

*capsici*, pathogenicity and sexual phenomena exhibited by, 636.

*cryptogea*, cause of tomato foot rot, 59.

induced disease of citrus and control in Brazil, 800.

*infestans*—see also Potato blight, late.

reaction of potato tubers of varieties differing in resistance to, 57.

*Phytophthora* Continued.

*infestans*—continued.

sporangial germination and zoospore differentiation, effect of electrolytes and nonelectrolytes, 52.

*parasitica* spread in Virginia, 336.

pathogenic species in water, 790.

spp. on citrus in South America, 60.

tomato disease new to Ontario, 490.

Pickering, T., on beef cattle, dairying, and cider, 143.

Pickles, dill, effect of pasteurization, N.C. 122.

Pickleworm control, rate of application of derris-talc dusts for, 74.

*Picramnia* to *Pinus*, host-parasite check list revision, U.S.D.A. 336.

*Pieris (Ascia) rapae*, see Cabbage-worm, imported.

Pies, quick frozen, 552.

Pig(s)—see also Sows and Swine.

body fats, component glycerides of perinephric and outer back fats, 818.

carcasses, firmness of fatty tissue, penetrometer for determining, 220.

carcass, leanness, effect of early growth rate, 818.

cervical abscesses of, Lancefield group E streptococci in, 532.

corn supplements for, U.S.D.A. 662.

disease, so-called baby, studies, 882.

economy of gains in, factors associated with, Ala. 610.

economy of gains in, transmission of factors, 225.

effect of phenothiazine on hemoglobin concentration and erythrocyte and leucocyte counts, 833.

effect of wheat germ supplements, 516.

efficiency as transformer of energy, N.H. 515.

electric hovers for, U.S.D.A. 662.

experimental infection with swine thorn-headed worm, 827.

fall, growing and fattening, vitamin A and D and protein supplements for, 515.

fattening, oats, barley, and corn compared, Miss. 79.

fattening rations, Miss. 78.

fattening value of soybeans for, N.C. 77.

feeding, P.R.U. 78.

feeding and management, Ga.Coastal Plain 225.

feeding experiments, Kans. 366.

feeding, spelt v. oats for, Mich. 79.

fertility in, 766.

garbage-fed in San Francisco, *Trichinella spiralis* in, 683.

gastrointestinal tracts, pH value of contents, 663.

grain-fed and garbage-fed, diagnosis of trichina infections, 827.

grain-fed and garbage-fed, reactions to intracutaneous injections of diluents, 827.

## Pig(s)—Continued.

- growing on limited grain rations, Nebr. 76.
  - hemophilia-like abnormality, physiology and inheritance, 765.
  - hereditary anomalies in, 313.
  - houses for Indiana, Ind. 98.
  - house, heating and ventilation, N.Dak. 690.
  - lipids of duodenal mucosa during fat absorption, 229.
  - market, types and grades, Ind. 76.
  - nerve degeneration and incoordination in, prevention for, U.S.D.A. 662.
  - newborn, acute hypoglycemia in, 243.
  - newborn, death loss in, Ind. 76.
  - nutrient requirements, 229, 816.
  - oat pasture as protein supplement and basic slag as mineral supplement for, Ala. 662.
  - oil meals v. plant and animal proteins for, Nebr. 76.
  - pathogenic acid requirement, 818.
  - parasites and treatment for removal, U.S.D.A. 676.
  - pasture comparisons with, Miss. 816.
  - potassium requirements, 818.
  - protein supplements for, Ind. 76.
  - receiving soybeans, calcium and phosphorus requirements, Ind. 76.
  - record of performance work with, 225, 662.
  - riboflavin deficiency in, 515.
  - spring-farrowed, electric heat in brooding, Ind. 97.
  - stillbirth in, causes and control, 366.
  - suckling, feeding, Miss. 572.
  - Sudan grass pasture and concrete wallows for, Tex. 226.
  - vaccination with anti-swine-erysipelas serum, U.S.D.A. 676.
  - vitamin D requirements, 366.
  - with dysentery, bacterial flora of, Ind. 87.
- Pigeon(s)—
- genetic hermaphroditism in strain of, 766.
  - pox virus, propagation in avian eggs, Ill. 88.
  - sexually dimorphic factor in, 765.
  - somatic mutations in, production, with X-rays, 765.
  - thiamin-deficient, recovery of virus morphologically identical with psittacosis, from, 678.
- Pigeonpeas and other legumes, comparative forage production, P.R.U. 318.
- Pigments, plastid, physical and photochemical properties, 606.
- Pimientos, *see* Pepper(s).
- Pine(s)—*see also* White pine.
- Austrian, needle blight of, 803.
  - beetle, mountain, cold hardiness in California forests, 363.
  - beetle, western, cold hardiness in California forests, 363.
  - blister rust, *see* White pine blister rust.

## Pine(s)—Continued.

- California, scale insects as enemies of, 657.
  - jack, seed studies, 486.
  - loblolly, nursery stock development, effects of soil treatments, 335.
  - loblolly, succession on abandoned agricultural land, soil changes associated with, 487.
  - longleaf, damping-off, 350.
  - pitch, posts, preserving, Conn.[New Haven] 49.
  - ponderosa, second cut, unmerchantability in, 786.
  - red and white, effect of spacing on growth, VI. 335.
  - root disease of Jeffrey and ponderosa varieties, 350.
  - Scotch, dormancy of seed, effect of light and temperature, 622.
  - second-growth longleaf, hail damage in, 487.
  - second-growth, quantity and quality factors as affected by stand, Ala. 634.
  - shortleaf, early effects of pruning young trees, 786.
  - shortleaf, fertilizer trials for improved establishment, 335.
  - slash, adaptations studies, Tex. 198.
  - slash and loblolly, underplanted in a hardwood stand, selectivity studies, Ala. 634.
  - southern, little leaf disease, Ala. 803.
  - southern, polyembryony in seeds, 335.
  - southern, pruning, U.S.D.A. 786.
  - western, red rot control, 504.
- Pine-oak rust, distribution and suggested control, U.S.D.A. 650.
- Pineapple(s)—
- fruits, keeping quality, effect of waxing, P.R.U. 42.
  - growth, effect of pH of culture solution, P.R.U. 42.
  - iron chlorosis, P.R.U. 51.
  - protein-digesting enzymes of, U.S.D.A. 582.
  - water culture experiments, P.R.U. 196.
  - waxing at different growth stages, effects, P.R.U. 48.
- Pinus*—
- armandi*, reproduction of, 198.
  - host-parasite check-list revision, U.S.D.A. 336.
  - lambertiana*, oogenesis and fertilization in, 312.
  - monophylla*, oogenesis and fertilization in, 312.
  - virginiana*, mycorrhizal short-roots, variations in form, 760.
  - yunnanensis*, reproduction of, 198.
- Piper* to *Populus*, host-parasite check-list revision, U.S.D.A. 636.
- Pittosporum* virus diseases, U.S.D.A. 336.
- Pituitary—
- anterior—
  - autoplastic grafting in male rats, 466.

## Pituitary—Continued.

## anterior—continued.

extract, effect on vitamin A and fat metabolism in fowl, 517.

extracts, treatment of lactating cows with, 822.

growth hormone of, bio-assay, 767. mamnogenic lobule-alveolar growth factor, biological assay, 671.

of cattle, effects of implantation on gonads of immature rat, 464.

of dwarf mice, function of metabolic active hormones in, 178.

thyrotropic hormone of, purification, 614.

cattle, effect on mammary growth of spayed hypophysectomized rats, 31, extract and refeeding, effect on ovaries of undernourished guinea pigs, 466.

factors, posterior, which contract lactating mammary gland, assay, 671.

follicle-stimulating fractions, preparation and properties, 436.

from different sources, effectiveness of heme in augmentation, 465.

gland, gonadotropic activity, effect of method of desiccation and storage, 29.

gonadotropic hormone, site of elaboration, 31.

## lactogenic hormone—

effect of pregnancy, 31.

production of traumatic placentoma in rat, 376.

reactions with iodine and molecular weight, 376.

of hypothyroid young male rats, gonad-stimulating potency, 768.

of nursing rabbits, lactogen content, relation to litter size, 670.

of poultry, unfractionated extracts, gonadotropic potency, 461.

of rabbit, during growth, thyrotropic hormone in, 670.

of rabbit, gonadotropic hormone in, 760.

of rats treated with progesterone, histology and physiology, 614.

weight, effect of desoxycorticosterone acetate, 376.

Placenta, retained, cause and treatment, 387.

## Plague—

epizootic in squirrels, burrowing owl as host of infecting parasite, 805.

studies of southern British Columbia, relation of rat fleas, 353.

## Planetree—

canker-stain disease, symptoms, dissemination, and control, 803.

diseases and other disturbances, 802.

leaf spots, fungi involved in, Calif. 803.

London, rosy canker due to gas injury, 211.

Planimeter, inexpensive, construction and operation, 787.

Planoflex for evaluating pliability of fabrics, description, 568.

## Plant(s)—see also Vegetation.

absorption of radiant energy in, 450.

## Plant(s)—Continued.

alpine, ultraviolet radiation as climatic factor for, 591.

amide synthesis in, 303.

and cuttings, effect of vitamin B<sub>1</sub> on, 777.

annual occurrence, effect of certain desert shrubs, 751.

as curiosities by certain southeastern Indian tribes, 450.

ash constituents, microdetermination, 584.

assimilatory capacity in course of development, 22.

boron starvation in, control, 161.

breeding—see also Heredity, Hybridization, and specific plants.

new methods, 323.

studies, Tex. 189.

studies, head thresher for, 395.

use of colchicine in, extension of use, 21.

## bug, rapid—

effect of calcium arsenates, 67.

insecticides for, comparison, 66.

studies, Tex. 213.

bug, tarnished, effect of calcium arsenates, 67.

bugs of Illinois, 510.

## cell(s)—

action of insulin on, 754.

cytoplasm, 308.

enzyme action in, deliberate alteration of prevailing direction, 24.

growing epidermal, production of solutes in, 756.

intake of radioactive isotopes, 305.

modifications induced by vitamin B<sub>1</sub>, 303.

relations of bioelectric phenomena to ionic permeability and to metabolism, 305.

salt accumulation by, 304.

surface, binding of ions by, 305.

chromosomes, see Chromosome(s).

communities and secondary succession in South Dakota, 451.

communities of Kaibab Plateau, Arizona, 450.

composition, effect of industrial contaminants, U.S.D.A. 723.

constituents, chemistry of, U.S.D.A. 723.

cultivated, new systematics of, 751.

cultivated, of Hawaii before discovery of Europeans, 19.

culture in nutrient solutions, Tex. 600.

## cuttings—

carbohydrate and nitrogenous constituents, effect of hormone treatment, 327.

effect of vitamin B<sub>1</sub> and other growth substances, Ind. 42.

effect of vitamin B<sub>1</sub> treatment, 327.

root formation, use of lanolin emulsions for stimulation, 777.

rooting and growth stimulated by heteroauxin, 304.

## Plant(s)—Continued.

- cuttings—continued.
  - rooting, effect of talc dusts containing phytohormone, nutrient salts, and mercurial disinfectant, 327.
- cyanogenetic, analysis, use of chloroform to accelerate cyanogenesis in, 245.
- defense mechanisms, 340.
- development, combined effects of potassium supply and growth substances, 453.
- development, effect of leaf extracts and other organic substances, 304.
- disease(s)—*see also* Fungi(us) and *different host plants*.

- roots, *Anguillula multicincta* and other species on, 202.
- roots, types of bacteria associated with, 159.
- rust fungi, taxonomy, Ind. 51.

## Plant (s)—Continued.

- sap, bound water in, effects of temperatures and nutrition, 757.
  - selective absorption of cations by, 756.
  - selenium in, 757.
  - shoot apex, microtechnic for, 21.
  - short-day, photoperiodic reaction, role of environment in, 162.
  - short-day, structure of stems, relation to differentiation and abortion of blossom buds, 455.
  - species, regional differentiation in, 762.
  - suspected, feeding tests, Tex. 243.
  - synthetic ability, effect of vernalization, 758.
  - taxonomy, mass collections in, technic and use, 301.
  - tissue(s)—
    - and hydrocarbons, interaction, N.Y. State 454.
    - apparatus for washing, 455.
    - Pasternack's paraffin method modified for, 455.
    - pH determination in, 25.
    - succinic acid as metabolite in, 753.
    - total extraction of free auxin and auxin precursor, 153.
  - transpiration, *see* Transpiration.
  - tumors, effect of chemicals, 638.
  - valuable for wildlife utilization, propagation and field tests, Ind. 65.
  - virus(es)—
    - and pea nodule bacterium, serological reactions, 337.
    - differentiation by trypan blue reactions within infected tissue, 488.
    - nomenclature, 639.
    - preparations, X-ray and crystallographic studies, 791.
    - relation to vector and nonvector insects, 792.
  - water uptake and root growth, effect of inequalities in concentration of substrate, 757.
  - weather and winter drying, U.S.D.A. 50.
  - woody, *see* Woody.
  - world, phenology in, geographic representation, 302.
  - world, textbook, 300.
- Plantains, fertilizer tests, P.R.U. 34.
- Plasma—
  - membrane structure, in light of frost-hardening changes, 805.
- Plasmodium*—
  - oathemerium* in canaries, ducks, and fowls, modifications of, 384.
  - circumflexum*, cultivation experiments, 328.
  - cynomolgi* of monkey, infection of *Anopheles quadrimaculatus* with, 384.
  - gallinaeum*, southern house mosquito as new vector of, 360.
  - lophurae*, infection of *Anopheles quadrimaculatus* with, 384.
  - lophurae* infections of fowl, effect of intraperitoneal injections of carbon ink, 384, 685.

*Plasmodium*—Continued.

- lophurae*, mosquito transmission of, 660.  
 spp. in ducks, virulence and exoerythrocytic schizogony in, 384.  
*Plasmopara viticola*, cause of grape downy mildew, 800.  
 Plastic molding from cottonseed protein, Miss. 443.  
 Plastics, role in entomology, 352.  
*Platyptilia*—  
   *carduidactyla*, see Artichoke plume moth.  
   *williamsii* on artichoke, Calif. 507.  
*Platyura fulvipes* luminous larvae with spider traits, 811.  
*Ploecyta* rind disease of sugarcane, 496.  
*Pleuropneumonia*, contagious, in cattle, 676, 677.  
*Pleuropogon*, revision, 20.  
*Pleurotus* spp., growth rate, 61.  
 Plow moldboard shapes and materials, analyses, Ala. 688.  
 Plow trash shields, studies, Ind. 97.  
 Plowing-up campaign in Wales, labor requirements, 402.  
 Plum(s)—  
   Abundance, transmission of line pattern virosis to peach, 348.  
   bacterial canker relation to propagation methods, 647.  
   beach, chromosome number, 27.  
   borer, American, on top-worked pecan trees, control, 70.  
   breeding, Tex. 189.  
   chromosome determinations, Tex. 189.  
   horticultural varieties, 782.  
   pollen studies, 826.  
   polyploidy in, induction, 42.  
   variety tests, Ind. 41.  
   Victoria, fruit gumming, 349.  
   xenia in, 42.  
*Plusia signata* on tobacco, life history, 75.  
 Pneumonia—  
   calf, etiology and pathology, 242.  
   pathology, of food-producing animals, 242.  
   pneumococcal, sulfadiazine in treatment, 679.  
*Podagrion mantis* parasite of praying mantid egg cases, 812.  
*Podospaera leucotricha* on apple, 798.  
*Pogonomyrmex barbatus*, see Ant, red harvester.  
 Poinsettia—  
   new bacterial disease, N.J. 649.  
   scab caused by *Sphaceloma*, 211.  
   *Sphaceloma* scab, N.J. 801.  
 Poison ivy control, N.H. 318.  
 Poisonous plants, see Cattle poisoning.  
 Plants, poisonous, and specific plants.  
 Police power, organization requirements, for regulating rural land uses, 259.  
 Poliomyelitis virus—  
   in flies, detection, 362.  
   in urban epidemics, flies as carriers, 512.  
   insects as carriers, 807.

- Polistes* wasps, parasites of, 813.  
 Pollard proteins, biological value, 226.  
*Polychrosis viteana*, see Grape berry moth.  
 Polycythemia, cobalt, maintenance in rat, 127.  
 Polydactylism, suppression in fowl, 766.  
 Polydactyly in poultry, and linkage relations, 765.  
 Polydactyly, two types in chicks, 707.  
*Polygonum*, seeds, dormancy in, 450.  
*Polymedon* n.sp., description, 360.  
 Polyphenolase activity associated with darkening of boiled potatoes, 702.  
*Polyphylla perversa*, life history, 353.  
 Polyplodogenic—  
   activity of methoxyl derivatives of Lenzene and naphthalene, 454.  
   compounds, activity, effect of hydrogenation, 455.  
 Polyploids, induced, induced variants and progenies of, N.Y.State 454.  
 Polyploidy—  
   in *Solanum douglasii* and relatives, 750.  
   in violets, Vt. 312.  
   induction in beets by colchicine, 323.  
   production, use of colchicine in, N.H. 326.  
*Polyporus*—  
   *abietinus* and *Irpea fusconitaceus*, relation, 639.  
   *ellisiannus*, notes, 501.  
   *fletii* n.sp. from forest terrain, description, 491.  
   spp., history and diagnosis, 790.  
*Polyspora tint*, notes, 206.  
 Polystyrene, plasticized, mounting medium, 455.  
 Pond weed control, use of fertilizer for, 41.  
 Ponds for wildlife, U.S.D.A. 63.  
 Ponies, Shetland, basic colors and patterns in, 318.  
*Popilla japonica*, see Japanese beetle.  
 Poplar—  
   rusts attacking Italian hybrid variety, 504.  
   yellow, fertilizer trials for improved establishment, 835.  
 Population—  
   aging, of State and Nation, Ohio, 264.  
   analysis, preliminary, N.Dak. 410.  
   and farm land increase of Mississippi, Miss. 549.  
   aspects for our disorganized national economy, 409.  
   balance, farm and nonfarm, in rural areas, U.S.D.A. 852.  
   farm, movements, Colo. 696.  
   marginal, and rural poverty, Va. 698.  
   migration and its problems, U.S.D.A. 852.  
   migration and resettlement in western States, 401.  
   migration and settlement on Pacific coast, U.S.D.A. 265.  
   migration in a defense period, U.S.D.A. 852.  
   of Great Britain, vitamin B<sub>1</sub> status, 180.

## Population—Continued.

of insects, oscillations and host-parasite relation, 508.

physiology studies, 513.

problems, economic impacts, 409.

southern, past decade in, 409.

trends and their agricultural implications, 264.

*Populus*—

hybrids, wood quality, relation to growth rate, 786.

to *Prosopis*, host-parasite check-list revision, U.S.D.A. 636.

*Porcellio scaber* on artichoke, Cal. 507.

## Pork—

carcasses, standards for grading and composition and fat distribution, U.S.D.A. 662.

changes in during freezing and storage, Ind. 6.

color of lean and rancidity in fat during frozen storage, effect of temperature and humidity, 366.

frozen, palatability, cooking losses, and tenderness, Ind. 121.

grade and quality, Ind. 76.

muscle, riboflavin in, 133.

production, effect of feed and effect of sex on, U.S.D.A. 662.

production, peanut products for, Ga. 816.

softening with hominy feed, Ind. 76.

storage in freezer lockers, 122.

*Porricondyla gossypii*, notes, 221.*Portheiria dispar*, see Gypsy moth.

Posts cut from native species, preserving, Conn. [New Haven] 49.

*Potamogeton* sp. control in fish ponds by fertilization, Ala. 616.

## Potash—

availability of soil, measured by pot experiments, Tex. 160.

deficiency on heavily limed land, Ind. 16.

fertilizers, field experiments with, R.I. 18.

## Potassium—

available, in soils, limitation of soil tests for, Ala. 593.

chloride, method of granulation, U.S.D.A. 740.

exchangeable, in soils, determination of small amounts, 154.

in blood plasma, microdetermination, 438.

in leaf material, spectrographic determination, 154.

status of orchard soil, effect of mulch on, 300.

## Potato(es)—

acreages, production, price, etc., Del. 256.

aphid control on Long Island, 510.

Aucklander Short-top, masked virus of, 56.

bacterial ring rot, Ind. 51, U.S.D.A. 50, 201, 336, 788.

bacterial ring rot in Venezuela, 793.

bacteriases, causal organisms and detection, 637.

## Potato(es)—Continued.

beetle, Colorado, estimating population over large area, 214.

blight, late—

in New York, U.S.D.A. 50.

in Pennsylvania, U.S.D.A. 50.

resistance to, genetics and physiology of, 793.

studies, 788.

v. weather, Tex. 202.

blight resistant, origin in Ecuador and known as Aya papa, 643.

boiled, darkening, cause, 702.

breeding, Colo. 616, Ga. 772, Nebr. 33, U.S.D.A. 771.

breeding, genetics, and cytology, review of literature, 619.

breeding program, national, summary, 642.

certification work, Ga. 772.

consumer buying and store offerings [N.Y.] Cornell 408.

cooking quality, relation to soil reaction, irrigation, and mineral nutrition, 38.

cracking at harvesttime, reduction, 185.

crinkle-infected plants, nitrogen relations, 405.

cull, ethyl alcohol production from, Idaho 413.

diseases—

control, U.S.D.A. 642.

in Jamaica, 789.

studies, Nebr. 51, U.S.D.A. 336.

virus, and degeneration in, 644.

virus, detection in tubers, Me. 343.

virus, physiology, 495.

disks, metabolism, effect of pH and components of bicarbonate and phosphate buffered solutions, 604.

effect of humidity and temperature on water loss, rotting, and sprouting, Nebr. 33.

effect of sprouts on, 619.

endemic, of South America, geography of, 601.

fertilizer(s)—

and spacing studies, U.S.D.A. 772.

5-year factorial experiment, 184.

formulas and rates, Okla. 620.

tests, Colo. 616, N.C. 34, N.H. 317, Tex. 180.

tests, distributor for factorial design used in, 181.

fields, devising methods for erosion control, N.H. 298.

first-year seedlings, testing for *Fusarium* wilt resistance, 643.

flea beetle control, Conn. [New Haven] 65.

flower and berry production, effect of light intensities, 606.

green manure and size of seed tests, Ga. 772.

"haywire" disease of unknown cause, Nebr. 51.

## Potato(es)—Continued.

- heat and drought endurance studies, Nebr. 33.
- in Boston market, consumer preferences, 260.
- insect control, Nebr. 65.
- insects, Ind. 65.
- Kansas, market quality determined by Federal inspection, Kans. 546.
- leafhopper—
  - control, insecticidal and varietal resistance, 510.
  - injury to alfalfa, nature of, 808.
  - insecticides, method of testing, 69.
  - resistant, U.S.D.A. 771.
  - resistant variety, breeding for, 357.
- leak, a watery wound-rot in New Zealand, 56.
- leaves and tubers, comparative boron content, 306, 603.
- leaves, yellow mottling due to tobacco ring spot virus, 796.
- lightning injury to, N.J. 202.
- Macrosporium* rot, new, Colo. 636.
- measurement of mealiness in, Ind. 121.
- minor element studies on, 184.
- molds in markets, 639.
- mosaic and leaf roll, effects of place, N.H. 337.
- mosaic diseases, effects, 643.
- nematode disease, 207.
- problem of maintaining porous silt loam for, 473.

 spirochetes in Utah, and *Ornithodoros parkeri*, 815.
- Relapsing fever—Continued.  
 spirochetes, transmission by *Ornithodoros turicata*, 213.
- Relief—  
 families, 5-ct. milk in diets of, U.S.D.A. 716.  
 population in Oklahoma, rural and urban, Okla. 698.
- Remedies, new and nonofficial, 829.
- Renin, effect of high pressure on activity, 436.
- Reproduction, physiology of, experiments in by Bureau of Animal Industry, U.S.D.A. 609.
- Resazurin test for milk, 239.
- Research—*see also* Agricultural research.  
 in New England, appraisal and evaluation, 260.  
 laboratories, regional, work of, U.S.D.A. 723.
- Reservoirs, flood-control and conservation, for regulation of snow-melt run-off, snow-survey predictions in, 444.
- Resins, processes for making from lactic acid, development, U.S.D.A. 819.
- Respiration—  
 energy of, effect of water content and carbohydrate accumulation, 102.  
 in apple leaves, effect of soil moisture, 329.  
 in apple leaves, effect of sulfur fungicides on, 489.  
 in living cell, 453.  
 of leguminous root nodules, 758.
- Respiratory activity, measure of, 21.
- Rhabdophaga heterobia*, studies, 214.
- Rhagoletis*—  
*cingulata*, *see* Cherry fruitfly.  
*fausta*, *see* Cherry fruitfly, black.  
*pomonella*, *see* Apple maggot.
- Rhipicephalus*—  
*appendiculatus*, transmission of *Theileria parva* by, 815.  
*sanguineus*, *see* Dog tick, brown.
- Rhizobium*—  
 cultures, numbering, identification scheme for, 159.  
*japonicum*, growth studies, 451.  
*leguminosarum* and plant viruses, serological reactions, 337.  
*leguminosarum* strains, morphology and physiology, 752.  
 spp., effect of selenium on growth and activities, 450.  
 strains, relation to soybean varieties, 601.  
*trifolii* filtrates, nodule bacteria culture in, effect, 752.
- Rhizoctonia*—  
*bataticola* notes, U.S.D.A. 788.  
*solani* from potato, pathogenicity test on sugar beets, 207.  
*solani*, strains, comparison, 491.
- Rhizoglyphus hyacinthi*, *see* Bulb mite.
- Rhizopus*—  
*nigricans*, spore germination tests of fungicides for variation in, 340.

*Rhizopus*—Continued.

soft rot of sweetpotatoes, prevention during storage, N.J. 795.

*sutinus*, production of substance B by, agencies affecting, 603.

*sutinus* spores, lethal effects of ultraviolet radiation, 790.

Rhode Island Station, notes, 576, 720.

*Rhododendron*(s)—

cuttings treated with  $\alpha$ -naphthaleneacetic acid, rooting, effect of nitrogenous compounds, 486.

freak weather injury, U.S.D.A. 50.

poisoning in cattle, 248.

wind scorch, Conn.[New Haven] 51.

*Rhopalosiphum pseudobrassicæ*, see Turnip aphid.

*Rhubarb*—

crown rot, due to *Pythium* spp. 200.

loss of vitamin C during cooking, 136.

*Rhus trilobata* seeds, new species of *Eurytoma* on, 364.

*Riboflavin*—

and flavor of dairy products, 276.

daily human requirement, Wis. 854.

deficiency

among Chinese, 504.

in dogs, 229, 230.

in pigs, 515.

determination, microbiological method, 587.

factor in economy of food utilization, 426, 427.

in pork muscle, 133.

in tissues, in vitro determination, 587.

legal requirement in enriched food, postponement of effective date, 553.

microbiological assay, inhibiting effect of urea on, 869.

of typical fruits, 869.

polarographic determination, 10.

relation to growth and paralysis in chicks, 517.

report on, 152.

requirement of rats, relation to dietary fat, 425.

requirement of turkeys for hatchability, 517.

synthesis, by bacteria and role in symbiosis, 309.

urinary, exception in man, 424.

*Rice*—

and byproducts, proteins, nutritive value, 415.

blast resistance, nature of, 794.

breeding, Tex. 180.

byproducts, feeding value, 665.

culture, tests, Tex. 180.

diseases and economic importance in Colombia, 57.

diseases, control, Tex. 202.

diseases in central Luzon, 496.

diseases in Philippines, 337.

economy of Monsoon Asia, 549.

fertilizer tests in rotations, Tex. 180.

germination, effect of carbon bisulfide on, 508.

*Rice*—Continued.

grain, thiamin distribution in, 562.

methods of applying fertilizers and carriers of nutrients, Tex. 180.

panicles, sterility, 795.

pests, 353.

polished, filtrate factor or factor W in, 135.

tolerance to soil reactions and hydrogen sulfide, Tex. 180.

varieties, comparative yields, U.S.D.A. 185.

variety tests, Tex. 180.

yields, effect of ammonium sulfate added to straw for turning under, U.S.D.A. 771.

yields, improvement by rotations, U.S.D.A. 771.

*Ricinus communis*, vascular network in node, development, 751.

*Rickets*—

and cereals, 125.

fat as factor in healing with vitamin D, 279.

in foxes due to unbalanced mineral supplements, Wis. 827.

of albino rats, calcium in soft tissues, 272.

*Rinderpest*—

immunization with goat virus, 248.

in buffaloes, immunizing value of dried goat spleen vaccine, 382.

virus, experimental infection in rabbit, 677.

River measurement, see Stream flow measurement.

River stages, daily, at gage stations, U.S.D.A. 295.

*Robin*(s)—

American, studies, 213.

gapeworm infection of, 301.

young, intestinal worms in, 391.

Rodent control, Conn.[New Haven] 64.

*Rodolia cardinalis*, see Vedalia.

Roentgen rays, see X-ray(s).

*Root*(s)—

attached and isolated, control of water transport in, 167.

excretions, effect on microbial activity, 790.

formation, effects of wounding and wound hormones, 165.

knot garden poll sponsored by Plant Nematode Council, U.S.D.A. 336.

knot in nursery trees, U.S.D.A. 337.

knot nematode(s)—

bulb treatment for, U.S.D.A. 337.

control, N.C. 51.

control by cultural practices, 351.

in Tennessee, U.S.D.A. 336.

on cotton, varietal reaction to, 343.

reaction of cotton varieties to, 489.

soil moisture relations, 200.

studies, Ga.Coastal Plain, 201.

knot, spot fumigation effective against, U.S.D.A. 788.

nodules, see Nodule bacteria.

**Root(s)—Continued.**

rot control, N.Mex. 203, Tex. 202.

rot fungus, southern, studies, U.S.D.A. 336.

Rootstocks, clonal and seedling, propagation and testing, N.Y.State, 477.

**Rose(s)—**

blooms, fading in color, cause, 633.

breeding, Tex. 189.

bud unions, failure caused by *Chalaropsis thielavioides*, 200.

chromosome determinations, Tex. 189.

diploid and polyploid species, crossing relations, 326.

diseases, control, 503, Tex. 202.

effect of growth substances, Ind. 42.

grafts, black mold of, control by chemical treatments, 802.

hips, data on, Conn.[New Haven] 550.

hybrid tea, culture experiments, Va. 49.

hybrid tea, effect of aeration on growth, 633.

hybridization, details of, 486.

mosaics in São Paulo, Brazil, 649.

Ophelia, parent of 483 varieties, 197.

powdery mildew, Conn.[New Haven] 51.

research at Cornell, 486.

root rot and chlorosis control on, Tex. 201.

seedlings, failure to respond to vitamin B<sub>1</sub>, 43.

soil, value of sterilization, 802.

species, fungus disease of, 503.

**Rosellinia—***pepo*, parasitism and important hosts, 800.

root rot of alfalfa in California, U.S.D.A. 50.

spp., taxonomic study, 450.

Rosh grass oil, notes, 164.

Rotation of crops, Minn. 773, Miss. 773, Nebr. 33.

Rotation of crops, fertilizer tests, Tex. 180.

**Rotenone—**

and rotenoids, present status, 355.

bearing roots, extracts of, solubilizers for, 654.

hydrogenation products, dihydrototenone in, detection, 585.

pharmacology of, 807.

Roughages, dry, nonlegume, v. legumes for cattle, Tex. 233.

Royal jelly, pantothenic acid in, 664.

**Rubber—**

program, cooperative Latin-American, progress, 787.

research in Latin America, U.S.D.A. 776.

**Rubbertrees, Para—**

diseases causing wounds on trunk, control, 804.

South American leaf spot disease of, 504.

sunscald of, 804.

Rubidium, effect on plant growth, 305.

**Rubus—**

fertility in, 42.

genus, in North America, 801, 751.

**Rubus—Continued.**

spp., propagation trials with, 630.

Rum fermentation, studies, P.R.U. 6.

Rum manufacture, results of study, P.R.U. 156.

*Rumex* seeds, injured, plant producing value, 622.**Ruminants—**

parasites and treatment for removal, U.S.D.A. 676.

vitamin A deficiencies in, 679.

**Run-off—**

and erosion, effect of mulching and cultivation methods, 746.

and erosion measurement, design of plot experiments for, 746.

and soil losses, differences, from terrace outlets on strip-cropped and on clean-cultivated areas, Ala. 592.

climatic factors affecting, U.S.D.A. 291.

determination from rainfall without using coefficients, 591.

for eastern Nevada, 1940 forecasts, 444.

from melting snow on Mokelumne Watershed, 444.

from small agricultural watersheds, 392.

rates and total soil loss, effect of crops and slopes, 594.

**Rural—**

areas, extension of urban characteristics into, 264.

art, expressions of, 698.

communities, impact of defense industries on, U.S.D.A. 852.

community studies, application of fundamental concepts in, 263.

Electrification Administration report, U.S.D.A. 102.

Electrification Administration work, relation to national defense, U.S.D.A. 835.

labor, *see* Agricultural labor.

leadership, discussion, Iowa 698.

life, measuring attitude toward, 263.

organizations in Wisconsin, Wis. 852.

public welfare administration and finance, [N.Y.][Cornell] 266.

regions of United States, 116.

relief in Illinois, Ill. 412.

schools, *see* School(s).

sociology, development, at University of Wisconsin, 263.

urban fringe, 263.

**Rust(s)—see also Cereal rust(s) and specific hosts.**

fungi, effects of atmospheric moisture and temperature on infection with urediospores of, 55.

reaction of wild and cultivated grasses to in the United States and Canada, U.S.D.A. 52.

spores, germination and staining in *Gymnosporangium*, 491.

tropical, descriptions, 639.

Rutabagas, *see* Swede.

Rye, effects of clipping, La. 32.

- Rye variety tests, Ga.Coastal Plain 179, Tex. 180.
- Ryegrass**—  
grazing, value for laying hens, 372.  
perennial, cystine and methionine in, 604.  
straw metabolism trials, 663.  
vernalization and short-photoperiod technique, 22.
- Sabulodes caberata* on artichoke, Calif. 507.
- Saccharomyces**—  
adaptive nature of enzymes, 303.  
*ceresiae* from yeast, molecular constitution, 581.  
spp., strains of yeasts related to, characteristics, 450.
- Safflower**—  
production tests, Tex. 180.  
promising types for oil seed production, U.S.D.A. 776.  
*Septoria* leaf spot on, U.S.D.A. 50.  
tests, Nebr. 33.

- serum phosphatase of, 821.
- skin disease due to ectoparasitic mite, 831.
- small grain-lespedeza pasture for, N.C. 77.
- soybean hay in ration for, N.C. 77.
- stiff, studies, Tex. 243.
- supplementation of winter grazing in Transvaal, 228.
- Targhee breed, development, Utah 177.
- tick, control, Ga. 831.
- wild and New-Caucasian Merino, inter-specific hybridization, 611.
- wound healing, 251.

Sheets, qualities and prices available in Missouri stores, Mo. 717.

## Shelterbelt(s)—

- effect on wind velocities, Ind. 49.
- establishing, and agencies cooperating, U.S.D.A. 785.
- trees, iron chlorosis in, 803.

## Shigella—

- equirullis* infection in a sow, 532.
- strains, action of sulfanilyl guanidine, 386.

Shoes, sizing and fitting, analysis of practices and trends, U.S.D.A. 429.

## Shrubs—

- control for range improvement, U.S.D.A. 772.
- desert, effect on occurrence of annual plants, 751.
- ornamental, suitable for central Great Plains, tests, U.S.D.A. 776.
- ornamental, for New Mexico, N.Mex. 634.
- propagation by cuttings, Mass. 192.
- suitable for prairie-plains, nursery practice for, U.S.D.A. 197.
- treatment for root rot, Tex. 201.

Sieve tube translocation model, 760.

## Silage(s)—

- alfalfa, molasses- and phosphoric acid-, physiological effect on cows, 374.
- carotenoids in butterfat, 237.
- clover-molasses, feeding, 373.
- for fattening steers, Ind. 76.
- grass, comparison of different crops for, 227.
- grass, harvesting and storing, machines designed for, 680.
- grass, making and feeding, new developments in, 663.
- grass, making, nutritional and engineering problems, 840.
- grass, on Massachusetts dairy farms, Mass. 234.
- grass, storage, 841.
- lactate-fermenting anaerobic and facultative organisms in, 673.
- legume, for dairy cows, 373, Pa. 81.
- legume, grass-juice factor in and in milk produced therefrom, 375.
- phosphoric acid, chemical changes in, 671.
- pressure studies, U.S.D.A. 835.
- sorghum, v. Johnson grass hay, relative consumption by cows, Miss. 374.

## Silk—

- and rayon mixed fabrics, serviceability, physical properties affecting, 282.
- fabrics and wild silk and weighted silks, cleaning methods, comparison, 285.
- industry, Japanese, facing new crisis, U.S.D.A. 692.
- serviceability, physical properties affecting, 282.

Silverfish, behavior of, 656.

*Simulium nigroparvum*, blood protozoan of turkeys transmitted by, 243.

## Siphonaptera—

- further records for British Columbia, 353.

## Siphonaptera—Continued.

genera *Amphitus* and *Otenophyllus* in North America, 513.

## Sire(s)—see also Bull.

indexes, effect of selection of dams, 234.  
proved in dairy herd improvement associations, list, U.S.D.A. 235.

## Sirups, farm-made, U.S.D.A. 723.

## Skim milk—

cultured, quality, factors affecting, 240.  
dry, composition of ash, relation to neutralization, 734.  
foam, concentrated, production and use, 379.

## Skins, see Hides.

## Skunk(s)—

cabbage seed and pulp, data on, Conn. [New Haven] 550.  
prairie spotted, food habits, 805.  
spotted, technic for trapping and tagging, 351.

## Slide rules, circular, for solving linear equations, 787.

## Sludge—see also Sewage.

produced in activated sludge method, condition of, Wis. 836.

## Slues in Trinidad, control with meta bait, 305.

## Smut fungi—

crosses between, inheritance of sorus characters in, 457.  
method for characterizing, exemplified by British species, 789.

## Snail, biology and ecology, 827.

## Snapdragon(s)—

growth on Iowa soils, 196.  
rust in Europe, spread, 802.  
spontaneous tetraploid, 27.  
virosislike injury due to peach aphid on, 640.

## Snipe, food habits, 212.

## Snow(s)—

and rain gage, Ferguson recording, operation, U.S.D.A. 295.  
heat necessary to melt, determination, new technic, 444.  
local, in western New York, effect of Lake Erie on, 740.  
melt forecasting, rational program, 444.  
melt, studies, U.S.D.A. 294.  
melt, thermodynamics of, outline, 444.  
melting, high rates of, analysis, 444.  
survey(s)—

and conditions in Columbia, Kootenay, and Okanagan Basins, 444.  
California cooperative, 444.  
Nevada cooperative, forecast and results, 444.  
predictions in operation of reservoirs for regulation of snow-melt run-off, 444.  
studies, Colo. 686.

## Snowberry, round-leaf chemical composition, factors affecting, 583.

## Snowfall, annual, of Washington State, type curves and variability, 444.

## Snowmold, eastern, new facts about, 204.

## Soaps—

from rosin v. soaps from individual fatty acids, germicidal activity, 246.  
germicidal value, 246.

## Social—

agencies, rural, ecology in Pennsylvania, 119.  
sciences, rural, problems of graduate students in, 400.  
studies, rural, training and recruiting personnel in, 262.

## Society of American Bacteriologists, proceedings of local branches, 309.

## Sociological theories in Argentina, rural-urban conflict in, 549.

## Sodium—

chlorate, toxicity, relation to soil reaction, 449.  
fluoride as herbicide, 188.  
importance for plant nutrition, 300.  
selenite, toxicity to millet, effect of soil colloids, 418.

## Soil(s)—

acidification, varied sulfur composts v. aluminum sulfate for, Tex. 157.  
acidity in Georgia soils, 317.  
action of chlorate in, Calif. 297.  
adobe structure in, development, 296.  
aeration as determined by pore size, N.C. 16.  
aeration, importance of, 486.  
aeration, relation to crop production, N.C. 16.  
aggregates, stability, Minn. 747.  
alkali, see Alkali.  
alkaline-calcareous, effect of decomposition of organic matter on, 160.  
analysis, quantitative spectroscopic, 16.  
and climate, 294.  
and pastures in Massachusetts, historical background, Mass. 774.  
and water conservation, cooperative studies, Tex. 157.  
and Water Conservation Experiment Station, Navajo, in New Mexico, report, U.S.D.A., 298.  
and Water Conservation Experiment Station, Southern Piedmont, work of, Ga. 741.  
and water conservation instruments, U.S.D.A., 295.  
and water conservation program in Little Mill Creek Watershed of Ohio, 541.  
arable, of Oregon, irrigation requirement, Oreg. 99.  
as farm commodity or factory, 402.  
bacteria, numbers, plate-count method for determining, 158.  
base-exchange properties, rapid estimation, 731.  
building practices, approved, Ala. 691.  
carbon disulfide vapor in, movement, Calif. 297.  
Cecil, properties, effect of cultural treatments, 317.  
changes associated with tillage and cropping in humid areas, 159.

## Soil(s)—Continued.

- classification and constitution of pedosphere, 593.
- color, standards and names for, U.S.D.A. 741.
- conservation—
  - and land use studies, U.S.D.A. 744.
  - and wildlife management, U.S.D.A. 505.
  - data, interpretation for field use, 157.
  - demonstration project area, economic analysis of farming in, 119.
  - districts in action on land, U.S.D.A. 106.
  - economic and social implications, Miss. 297.
  - economics of, 401.
  - in Puerto Rico and Virgin Islands, U.S.D.A. 745.
  - needs of cotton-and-tobacco South, U.S.D.A. 402.
  - publications and visual information on, U.S.D.A. 266.
  - Service, report, U.S.D.A. 744.
  - studies, Ind. 16.
- conservationists, early American, U.S.D.A. 596.
- depletion, effect of erosion, Conn.[New Haven] 16.
- determining soluble salt content, conductometric method, 157.
- drainage as determined by pore size, N.C. 16.
- economics, neglected point in, 401.
- erodibility of upper Gila watershed, U.S.D.A. 595.
- erosion—
  - and related land use conditions, U.S.D.A. 298.
  - and run-off control, N.Y. State 448
  - and run-off, effect of mulching and cultivation methods, 746.
  - and run-off measurement, design of plot experiments for, 746.
  - and run-off on pastures, effect of slope, plant cover, and contour tillage, Vt. 296.
  - and water loss, relation to rainfall intensity, Miss. 17.
  - control, Nebr. 16.
  - control, value of legumes for, U.S.D.A. 35.
  - effect of cropping systems, Wis. 298.
  - equation, application to strip crop planning, 745.
  - in China, 745.
  - in cotton-and-tobacco South, correction methods, U.S.D.A. 402.
  - in potato fields, devising methods for control, N.H. 298.
  - losses, effects of slope, character of soil, rainfall, and cropping, Va. 447.
  - studies, Miss. 447.

## Soil(s)—Continued.

- extracts, phosphate in, determination, methods, 732.
- fallow, evaporation from, 747.
- fertility—
  - and improvement, Tex. 180.
  - biological aspects, 743.
  - exhaustion by soybeans under different potassium levels, Mo. 18.
  - legumes for N, U.S.D.A. 774.
  - programs, soil and plant tests as aids, 599.
  - relation to increased agricultural production for defense program, Utah 449.
- freezing and forest cover, 444.
- Gezira, dispersion studies, 745.
- Houston, microbial response to organic amendments, 456.
- infiltration study, U.S.D.A. 17.
- management on Long Island, N. Y., [N.Y.] Cornell, 447.
- management surveys, N.C. 16.
- microbiology, scope of, 158.
- minerals, separation, double centrifuge tube for, 296.
- modern conception and relation to plant growth, Minn. 741.
- moisture—
  - conservation, Nebr. 16.
  - control, use of avallameter in, 595.
  - determination, rapid method, 732.
  - loss, effect of mulching materials, 595.
  - measurement, four-electrode resistance method for, 594.
  - movement through silt loam, measurement, 157.
  - tensiometer, principles of, 836.
  - uptake and retention determined by distance to water table, 158.
- morphology, effect of tree roots on, 593.
- muck, *see* Muck soil(s).
- nitrate-nitrogen, determinations, with photoelectric colorimeter, 292.
- of Alberta, selenium in, 449.
- of Georgia, acidity, 317, Ga. 741.
- of Georgia, available nutrients in, 317.
- of Hawaii, sorption of potassium and ammonium, 18.
- of Indiana, classification, outline, 446.
- of Java, availability of indigenous phosphorus in, 299.
- of Montana, infertility in, causes, Mont. 449.
- of North Carolina, boron status, 317.
- of Oregon, humus for, Oreg. 17.
- of Puerto Rico, quantities of assimilable nutrients in, P.R.U. 296.
- of United States, boron content, U.S.D.A. 740.
- optimum nutrient balance in, Colo. 593.
- organic matter in, *see* Organic matter.
- permeability to water, Nebr. 16.
- phosphorus, solubility, Nebr. 16.
- porosity, noncapillary, apparatus for measuring on extensive scale, 594.

## Soil(s)—Continued.

- productivity, relation to farm building classifications, 260.
- productivity, requirements for, Miss. 17.
- properties, techniques and tools for determining, Mich. 16.
- science for the layman, N.Dak. 718.
- series of Puerto Rico, studies, P.R.U. 16.
- Solonetzhik, B horizons of, distribution of carbon within morphological columns from, 593.
- solution, pressure-membrane extraction apparatus for, 593.
- sterilization by fumigation, Tex. 157.
- structure, classification, 296.
- survey in—

- California, Sacramento-San Joaquin delta area, U.S.D.A., 157.
- Georgia, Catoosa Co., U.S.D.A., 593.
- Illinois, Warren Co., Ill. 296.
- Iowa, Story Co., U.S.D.A. 593.
- West Virginia, Greenbrier Co., U.S.D.A. 157.

- survey work, status, Tex. 157.
- surveys, data on, U.S.D.A. 740.
- synthetic, as bacteriological culture medium, 298.
- testing for deficiencies, N.J., 449.
- tests, chemical, Ga. 741.
- textures, field method for estimation, 402.

- type and composition, effect on pasture production, Va. 742.

- types, fertilizers for, Miss. 449.

- under permanent pasture, nitrate and ammonia in, 596.

- water, *see* Soil moisture.

- wilting coefficient, method for determining, 595.

- with different drainage characteristics, field percolation rates, 594.

## Solar radiation, data, 295.

*Solenopotes capillatus*, notes, 808.

## Sorbose, L-, reducing properties, 727.

## Soremouth of sheep and goats, Tex. 243.

## Sorghum(s)—

- and climate, U.S.D.A. 294.
- as root rot remover, Tex. 202.
- charcoal rot, new disease of, U.S.D.A. 787, 788.
- double cropping experiments, Tex. 180.
- dual-purpose, U.S.D.A. 771.
- effect of light and length of day on maturity, Tex. 180.
- fodder and alfalfa hay, relative net energy values, 515.
- germination and root development, 760.
- grain—

- and forage, nutritive value, Nebr. 80
- breeding, Colo. 616, Nebr. 33, Tex. 180.
- culture tests, Tex. 180.
- ethyl alcohol production from, Idaho 443.
- fertilizer tests in rotations, Tex. 180.

## Sorghum(s)—Continued.

## grain—continued.

- harvesting, 689.
- importance of sucker stalks in production, U.S.D.A. 771.
- storage studies, U.S.D.A. 835.
- irrigation tests, Tex. 180.
- variety tests, Ga. Coastal Plain 179, Nebr. 33, Tex. 180.
- yield, relation to leaf area, 473.
- hybrid vigor in, Tex. 180.
- inheritance studies with, Tex. 180.
- midge, life history and control, 221.
- planting tests, Nebr. 33.
- response to fallow and other tillage practices, Nebr. 33.
- silage, *see* Silage.
- smut studies, 789.
- v. corn, effects on succeeding crops, Tex. 180.
- varieties, forage yields, Tex. 180.
- varieties, improved, registration, 185
- yield, effect of vitamin B<sub>1</sub>, 182.

## Sorgo—

- Atlas, adaptation as silage crop, Ind. 32.

- breeding, Tex. 180.

- fertilizer tests, Ga. 772.

- sirup, clarification, use of Iowa clays for, 730.

- sugar, farm-made, U.S.D.A. 723.

- variety tests, Ga. 772, Ga. Coastal Plain 179, Nebr. 33, Tex. 180.

## South Carolina Station, notes, 720.

## South Dakota Station, notes, 720.

## Sowbug, scabby, on artichoke, Calif. 507.

Sows—*see also* Pig(s) and Swine.

- brood, and litter management, important factors in, Miss. 430.

## Soybean(s)—

- and cowpea proteins, comparative nutritive value, Ala. 700.
- and other legumes, comparative forage production, P.R.U. 318.
- and soybean products, special research, U.S.D.A. 723.

- Biloxi, effect of localized low temperature during photoperiodic induction, 168.

- breeding, Ind. 32, Tex. 180, U.S.D.A. 771.

- cambial growth, effect of day length, 307.

- carbohydrates, studies, 726, Ind. 6.

- culture tests, Tex. 180, Miss. 467.

- defoliation tests simulating grazing intensities, N.C. 34.

- diseases and control problems, 496.

- edible, culture, N.Y.State 477.

- edible, differing markedly in flavor and cooking quality, and resistant to beetle attack, U.S.D.A. 771.

- fertilizer tests, Ga. 772.

- germinating, nitrogen metabolism, Ind. 6.

- goitrogenicity, 77.

- hay in ration of sheep, N.C. 77.

**Soybean(s)**—Continued.

- humus v. agar cultures for nodule bacteria, 451.
- inoculation, improved culture media for bacteria, Wis. 771.
- inoculation tests, Nebr. 33, Tex. 180.
- meal and peanut meal v. trinity mixture for pigs, U.S.D.A. 662.
- meal, value for foxes, 368.
- meals v. cottonseed cake as protein supplements for fattening cattle, Nebr. 76.
- moisture in, 726.
- new strains, U.S.D.A. 774
- nodule bacteria in Philippines, 337.
- oil, expressed, sterol glucosides from. Ind. 6.
- oil, nonfat constituents, Ind. 6.
- oil, preparation of sterols from, Ind. 6.
- planting tests, Ga. 772.
- production in Iowa, Iowa 322.
- protein and mixed soybean-pork and soybean-egg proteins, biological values in human subjects, 555.
- protein, quality, effect of hydrolysis, Wis. 854.
- protein, résumé and bibliography, U.S. D.A. 150.
- seed composition, effect of environment, 322.
- seedling defects in, significance of constitutional deficiency, 207.
- seeds, downy mildew on, U.S.D.A. 788.
- stem growth, effect of day length, 307.
- under different potassium levels, relation to nitrogen fixation and soil fertility, Mo. 18.
- varieties, relation to *Rhizobium* strains, 601.
- varieties, shattering among, N.C. 34.
- varieties, differences in ability of strains of root-nodule bacteria to fix N in, Wis. 774.
- variety tests, Ga. 772, Ga. Coastal Plain 179, La. 32, Miss. 467, 772, N.C. 34, Nebr. 33, P.R.H. 318, Tex. 180.
- vitamin content, N.C. 80.

Sparrow, Java, studies, 351.

Spatterdock control by cutting, Ala. 616.

Spectrophotometer, photoelectric, improvements in, Ind. 6.

**Spermatogenesis**—

rate in rabbit, 768.

stimulation by various substances, 771.

**Spermatozoa**—

bovine, preservation in yolk-citrate diluent and field results from use, 520.

duration of fertilizing capacity in female genital tract of rat, 613.

viability in abdominal epididymis and failure of motile sperms to fertilize ova, 768.

**Sphaceloma**—

*fauretii* scabiosa, cuprous oxide mixture for control on citrus, 648.

genus, revised description and type species, 450.

**Sphaceloma**—Continued.

n.spp. on hosts of economic importance, 52.

*ricini* n.sp., description, 202.

sp. causing poinsettia scab, 211.

Sphagnum for seed germination inhibits damping-off losses, 491.

*Spicaria coccospora* n.sp., notes, 62.

**Spider**—

black widow, treatment for bite, 223.

mite, *see* Red spider.

notes, Conn.[New Haven] 65.

red, *see* Red spider.

*Spilonota ocellana*, *see* Budmoth, eye-spotted.

**Spinach**—

breeding for disease resistance, Tex. 202.

downy mildew and causal organism, 489.

effects of calcium and pH, 779.

increases in yield from early spring N applications, Miss. 777.

New Zealand, calcium oxalate in, Ga. 854.

New Zealand, seed germination, N.Y.State 477.

white rust, histopathology, Tex. 202.

yield and mineral composition, effect of borax, Mich. 599.

Spinal fluid, vitamin B<sub>1</sub> in, 131.

*Spirochaeta gallinarum* cultivation, 686.

Spray(s)—*see also* Fungicides, Insecticides, and specific forms.

copper, *see* Copper.

injury, effect of temperature and season, 796.

injury studies, 638.

materials and residues, N.Y.State 503.

materials, stickers for, Conn.[New Haven] 64.

oil, *see* Oil sprays.

outfits, portable and stationary, comparison, Ind. 42.

residue problem, 508.

test of capacity to break rest period of peach buds, 47.

wetting power and retention by fruit surface, relation, 480.

Spraying installations, costs of power for, Ind. 103.

**Spruce**—

foliage insects in Canada, 216.

sawfly, European, diapause and related phenomena in, 364.

sawfly, European, in America, separation from *Gilpinia polytoma*, 813.

silvicultural requirements, 335.

white, bisexual cone of, 787.

**Squash**—

breeding, Ga. 776, N.Y.State 477.

breeding for disease and insect resistance, N.Y.State 477.

culture, N.H. 326.

fertilizer and storage tests, 191.

productivity of F<sub>1</sub> hybrids in, 600.

stored, external treatments for, N.H. 326.

summer, breeding, Conn.[New Haven] 41.

## Squash—Continued.

summer, comparative earliness and productiveness of first and second generation, 625.

vine borer control, Conn.[New Haven] 65, N.Y.State 651.

Squill, bulb rot, 802.

Stableflies, abundance, seasonal occurrence and effect of host attractiveness, 512.

*Stagnicola bullimoides tchella*, biology and ecology, 827.

## Stagonospora—

*arenaria* on grasses, 792.

*curtisii*, notes, 502.

## Stains—

biological, nature and uses of dyes employed in, 163.

standardization, progress in, 455.

Standards of living of tenant families, improving, Miss. 875.

Staphylococic toxins, studies, 678.

## Staphylococcus—

*candidus*, CO<sub>2</sub> requirement, 761.

nucleus-like structure in, 608.

## Starches—

chemical studies, U.S.D.A. 723.

reducing power, 733.

wheat, comparative baking quality, N.Dak. 580.

Starlings, combating objectionable roosts of, 251.

Steel, bacterial corrosion, 309.

Steers—see also Cattle, beef.

beef, bonemeal and dicalcium phosphate for, Tex. 225.

calf production and gains in, U.S.D.A. 662.

fattening, silage for, Ind. 76.

fattening, utilization of home-grown feeds in, Tex. 664.

fertilization and management of pastures and cottonseed cake for, U.S.D.A. 662.

grade, relation to efficiency of feed utilization, U.S.D.A. 662.

pasturing, clovers v. carpet grass for, Ga. 816.

quality and grade of carcass, effect of various rations, Ga. 816.

roughage for, ryegrass pasture v. corn silage, U.S.D.A. 662.

urinary calculi in, relation to milo grain, Tex. 225.

yearling, finishing on lespedeza with and without white shelled corn, U.S.D.A. 662.

## Stemphylium solani—

on tomato, U.S.D.A. 336.

on tomato, geographical extension, U.S.D.A. 201.

Stenosis studies on cotton, 641.

## Sterility—

due to ovarian dysfunction, 242.

in cattle, from practitioner's viewpoint, 242.

partial, inherited, and embryonic mortality in rat, 766.

## Sterol(s)—

glucosides from expressed soybean oil, Ind. 6.

preparation from soybean oil, Ind. 6.

Sticktight flea and burrowing owl, role in spread of plague, 805.

*Stictocapha lermis* eggs, effect of dormant oil sprays, 69.

*Stigmella plataniracemosae* on *Platanus* spp., Calif. 803.

*Stigmima platani* on *Platanus* spp., Calif. 803.

## Stillboestrol—

absorption of pellets implanted in rat, 29.

effect on mammary gland of small animals, 377.

effect on sexual receptivity in spayed guinea pigs, 461.

## Stinkbug, southern green—

food plants of, 352.

studies, Tex. 214.

Stock, see Livestock.

Stock foods, see Feeding stuffs.

Stocks, growth on Iowa soils, 196.

Stockyards fever, see Septicemia, hemorrhagic.

## Stomach worm(s)—

drench, efficiency of copper sulfate and nicotine sulfate, variations in, 386.

eggs in utero and in feces, comparison, 365.

immunity of cattle to, 681.

immunity to, effect of low plane of nutrition, 827.

in calves, effect of milk diet, 827.

in cattle, immunity to, 383.

in sheep and goats, Tex. 243.

in sheep, experimental infection, 677.

in vitro conditions favoring ecylsals at end of first parasitic stage, 383.

infections, blood picture in, 383, 827.

male genitalia, musculature, 827.

resistance of calves to natural reinfection with, 828.

Stomatitis, erosive, of cattle, 382.

*Stomoxys calcitrans*, see Stableflies.

## Storage—

investigations, Ind. 41.

plants, refrigerated, in Eastern Panhandle, W.Va. 110.

work of Bureau of Agricultural Chemistry and Engineering on, relation to national defense, U.S.D.A. 835.

## Storm(s)—

and floods, U.S.D.A. 294.

characteristics of Sacramento Basin, 444.

of hurricane type, damage to small streams and lowlands from, 739.

## Stoves—

gas and electric, studies, U.S.D.A. 716.

gasoline and pressure kerosene, studies, Nebr. 142.

## Straw—

pulp feeding trial in England and Wales, 668

## Straw—Continued.

treated with caustic soda for beef production, 366.

## Strawberry(ies)—

Blakemore, productiveness and quality, relation to width of thinned row, 628.  
breeding, Conn.[New Haven]41, N.C. 42, Tex. 189.

carbon dioxide treatment in transit and storage, 47.

culture in Missouri, Mo. 630.

developed by station, characteristics, N.Y.State 195.

disca es, U.S.D.A. 799.

diseases in Oregon, U.S.D.A. 336.

fall setting in Missouri, 629.

fertilization and liming N.C. 42.

fertilizer requirements, N.Y.State 477.

fruit production, relation to leaf area, N.C. 42.

growth, effect of preceding crop, N.C. 42.

new, descriptions, U.S.D.A. 776.

parthenocarpic, experimental induction, 195.

planting stock, methyl bromide fumigation, 658.

plants, cold resistance, effect of time of mulching, 47.

plants, overbearers, mulch requirements, 783.

red core disease, 648.

red stele, breeding for resistance, 210.

respiration of fruits, U.S.D.A. 195.

Rocky Mountain, hardiness, 629.

root development, pattern under matted and thinned row, 629.

root-infesting weevils, control, 810.

stunt disease, 60.

Tennessee Shipper, promising new variety, Tenn. 484.

varieties, Ga. 776.

varieties, reaction to virus of yellow-edge 210.

yield and grade, effect of spacing, R.I. 628.

Strawflower *Verticillium* wilt, 349.

## Stream(s)—

flow and snow cover in Colorado, correlation, 444.

flow records of Pennsylvania, 739.

gaging, methods and equipment used in, 687.

small, high water in, due to thunderstorms, 739.

Street vendors, volume of sales by, P.R.U. 104.

*Strepsiptera*, revision, 220.

*Streptobacillus moniliformis*, notes, 677.

## Streptococci—

equine hemolytic, studies, 677.

hemolytic, type differentiation, 677.

Lancefield group E in cervical abscesses of swine, 532.

mastitis, detection, efficiency of microscopic examination of incubated milk samples, 89.

## Streptococci—Continued.

mastitis, in milk, activity, effect of udder coccus, 90.

## Streptococcal infections—

experimental, effects of sulfanilamide and sulfapyridine, 678.

hemolytic, use of sulfadiazine in, 679.

*Streptococcus*—*agalactiae*—

activity in milk samples, effect of udder coccus, 90.

entozon in treatment, 248.

in milk, bacteriological techniques for revealing, 673.

in test cups, sterilization, 91.

*hastitidis*, dehydrogenases of, 243.

*paracitrovorus*, CO<sub>2</sub> requirement, 761.

spp., flavor development in salted butter by pure cultures of, Iowa 379.

## Strongyles—

horse, survival and development of eggs and preinfective larvae, 252.

removal from horses, phenothiazine for, 390.

*Strongyloides papillosus* of sheep, failure of phenothiazine as anthelmintic against, 532.

Strongylosis, equine, phenothiazine treatment for, 253.

Students, women, in home economics, arts and sciences, and education, social and personality characteristics, 119.

Subsoils, humid, relative productivity, Minn. 742.

Succinoxidase activity of fresh rat tissues, stimulatory effect of calcium, 558.

*Suckleya* in Colorado, 600.

Sucrose solutions, boiling-point elevation, 738.

## Sudan grass—

arsenic accumulation in, 604.

breeding, Tex. 180.

culture tests, Miss. 772.

growth, effect of 2-yr. sericea stubble on, A'a. 616.

growth-promoting value, effect of curing methods, Nebr. 76.

meal for laying hens, Nebr. 76.

new strains, U.S.D.A. 774.

pasture for pigs, Tex. 226.

poisoning of cattle, 831.

smut in Argentina, 490.

strains, grazing tests, Tex. 181.

v. buffalo grass on dry land and under irrigation, Tex. 181.

## Sugar beet(s)—See also Beet(s).

and beet sugar, chemical studies, U.S.D.A. 723.

*Aphanomyces* root rot, effect of phosphate, 345.

asexual propagation, 474.

black heart blight, 323.

black root, studies, 345.

blight, control, 323.

boron deficiency in, 344.

breeding, U.S.D.A. 771.

breeding for leaf spot resistance and other characters, 344.

## Sugar beet(s)—Continued.

- climatic relations, U.S.D.A. 291.
- curly-top resistance, effect of age of plant, 200.
- curly-top resistant varieties, performances, 344.
- fertilizer tests, Ind. 32, Mont. 467.
- Fusarium* yellows, resistance to, 324, 344.
- glutamine and asparagine metabolism, effect of high concentrations of CO<sub>2</sub>, 750.
- grown for seed, boron deficiency relations, 324.
- grown for seed, insect isolation-cage studies, 652.
- heart rot, borax for control, 345.
- in rotations, seedling diseases, phosphate deficiency, and *Fusarium* yellows, 344.
- irrigation tests, Tex. 180.
- leaf spot, breeding for resistance to, 323.
- leaf-spot resistant variety, new, 345.
- machinery, Colo. 686.
- mechanical thinning, Colo. 620.
- merits of early planting in northern Great Plains, U.S.D.A. 772.
- mosaic, effect on seed yield, 344.
- natural occurring root graft in, 600.
- pathogenicity tests of *Rhizoctonia solani* from potato, 207.
- phosphate deficiency in, U.S.D.A. 200.
- pollen tube, nuclear phenomena in, 323.
- production and improvement, papers on, 322.
- root rot survey, 345.
- Sclerotium* rot, reducing with nitrogenous fertilizers, 795.
- seed ball extracts, studies, 324, 344.
- seed balls, ammonia from, effect on germination tests, 38.
- seed crop in Pacific Northwest, black blighting and yellow stunting of, U.S.D.A. 748.
- seed germination, toxic effects of ammonin, 644.
- seedling diseases, soil and seed treatment experiments, 344.
- sucrose loss and changes of nitrogen constituents with delayed topping, 474.
- U. S. 22, improved variety, U.S.D.A. 771.
- variety U. S. 200 × 215, leaf spot-resistant, U.S.D.A. 771.
- Verticillium* wilt, 344, 636.
- yield and mineral composition, effect of borax, Mich. 599.
- yields, effects of manure, legumes, and phosphate, Nebr. 33.

## Sugarcane—

- and cane sugar, chemical studies, U.S.D.A. 723.
- borer, caterpillars, rearing large numbers, P.R.U. 66.
- borer control, 512, U.S.D.A. 511.
- borer, control with parasites, P.R.U. 66, 220.

## Sugarcane—Continued.

- breeding, P.R.U. 34, U.S.D.A. 771.
  - chlorotic streak spreading in Louisiana, U.S.D.A. 788.
  - chlorotic streak, transmission by a leaf-hopper, 645.
  - climatic relations, U.S.D.A. 294.
  - diseases in Cuba, 496.
  - farm, resident laborers on, La. 853.
  - fertilizer tests, P.R.U. 318, Tex. 180.
  - fiber, hemicelluloses, 150.
  - growing, economic phases, revealed by station studies, P.R.U. 287.
  - industry of South Africa, control in, 401.
  - irrigation, trash disposal, and green manuring tests, P.R.U. 34.
  - new promising varieties, U.S.D.A. 771.
  - nitrogen nutrition, time-of application test, 38.
  - parasite on *Christisonia wightii*, 57.
  - plant, fluctuations in moisture content, 25.
  - potassium requirements, 39.
  - production machinery, 839.
  - root rot, 207.
  - rootstock weevil attacking sorghum in Kansas, 364.
  - seed germination, comparison of media, P.R.U. 34.
  - sirup, farm production, U.S.D.A. 293.
  - smut in Bihar, 407.
  - variatal differences, 38.
  - variety tests, P.R.U. 318, Miss. 772.
- Sugar(s)—*see also* Dextrose, Glucose, Lactose, Sucrose, *etc.*
- beet and cane, chemical studies, U.S.D.A. 723.
  - manual, Puerto Rico, 474.
  - plants, research on, 323.
  - relative sweetness, effect of concentration, 7.
  - transformation in excised barley shoots, 753.
- Sulfadiazine—
- absorption and excretion, 679.
  - studies, 679.
- Sulfaguanidine feeding for control of cecal coccidiosis of chickens, 833.
- Sulfamido compounds and azochloramid, synergistic action on pathogenic microorganisms, 829.
- Sulfanilamide—
- conjugation by pathological tissue in vitro, 829.
  - therapeutic activity in mice, effect of dietary factors, 246.
- Sulfanilylguanidine—
- in swine and sheep, blood concentration studies, 532.
  - selective action on *Salmonella* types, 386.
- Sulfapyridine—
- action in cattle, 92.
  - and quinine, therapeutic incompatibility, 829.
  - therapy in local infections, 829.
- Sulfathiazole, dimorphism, 583.

- Sulfate in presence of chromate, determination, 729.
- Sulfo merthiolate as germicide, 529.
- Sulfonamides, binding by plasma proteins, 929.
- Sulfur—  
 as plant nutrient, 598.  
 as stomach insecticide, 353.  
 composts, varied, v. aluminum sulfate for soil acidification, Tex. 157.  
 compounds, chemistry and metabolism, 113.  
 dusts, adhesives for, 489.  
 effect on chicks, 253.  
 fungicides, evaluating for powdery mildews, 200.  
 in proteins, 726.  
 mixtures, *see* Lime-sulfur.
- Sun lamps for poultry, Ohio 519.
- Sunflower(s)—  
 cultivation and uses, U.S.D.A. 39.  
 cytological studies, 456.  
 leaf parts, action of enzymes in, 23.  
 of North Dakota, N.Dak. 430.  
 seed v. yellow corn for turkeys, Nebr. 76.  
 stems, response to plant growth substances, 165.  
 varieties, forage yields, Tex. 180.  
 variety, oil-yield tests, P.R.U. 6.
- Sunlight—*see also* Light.  
 relation to yield and quality of vegetation, Tex. 181.
- Sunspot data, 295.
- Surra in horses in Philippines and North Borneo, treatment, 533.
- Superphosphate—  
 in limed soils, end product, new concept of, 749.  
 triple, for pasture improvement, effect on soil and water losses, Va. 746.
- Surplus Marketing Administration, report, U.S.D.A. 819.
- Swallow bug, infestation of school building by, 61.
- Swamp fever, *see* Anemia, equine infectious.
- Swede *Rhizoctonia* rot, 207.
- Sweet corn—*see also* Corn.  
 as cash crop on dairy farm rotation, N.H. 317.  
 breeding, Ind. 41, Miss. 776, Tex. 180, 180.  
 breeding activities and new promising hybrids, 778.  
 canning trials, 778.  
 effect of preceding beet crop, N.Y.State 477.  
 fertilizer tests, Ohio 180.  
 germination, effect of stage of maturity at time of harvest, 328.  
 hybrid, breeding, Conn.[New Haven] 41.  
 hybrid varieties for New York, N.Y.State 190.  
 in Alberta, 778.  
 inbred lines, sugar loss on storage, Ind. 6.  
 spacing, N.Y.State 477.
- Sweet corn—Continued.  
 varieties and breeding, Miss. 776.  
 varieties, new, N.Y.State 625.  
 variety tests, N.Y.State 477.
- Sweet gum, bleeding necrosis, N.J. 211, U.S.D.A. 336.
- Sweet pea, curliness of flowering, inheritance, 764.
- Sweetclover—  
 as intercrop in rotation, Ind. 32.  
 breeding, Nebr. 33.  
 clipping and palatability tests and coumarin determination, Nebr. 33.  
 culture, tests, Tex. 180.  
 disease, hemorrhagic, bio-assay of hemorrhagic concentrates, 249.  
 management in pasture system, No. 621.  
 new strains, U.S.D.A. 774.  
 planting tests, Nebr. 33.  
 poisoning in cattle, effect of alfalfa lipids, 248.  
 varieties, winterhardiness tests, Tex. 180.  
 variety tests, Nebr. 33, Tex. 180.  
 white, roots and root nodules, histology, 456.
- Sweetpotato(es)—  
 acreages, production, price, etc., Del. 256.  
 and vines stored in pit silos, Ga. 816.  
 as crop to follow cotton, P.R.U. 621.  
 breeding, 317, Tex. 180.  
 culture tests, Miss. 467.  
 dehydrated, stability of carotene in, S.C. 14.  
 dehydrated, v. shelled corn for fattening calves, Tex. 226.  
 dried, for finishing calves, Miss. 78.  
 feeding value, 225.  
 fertilizer tests, Miss. 467, N.C. 34, Tex. 180.  
 for commercial shipment, problems, 317.  
 for home use throughout the year, Ala. 616.  
 for industrial purposes, delayed harvest, 324.  
 for starch, production and harvesting machinery, 316.  
 formulas and carriers of N, P, and K for, Ga. Coastal Plain 179.  
 handling and marketing, Iowa 406.  
 meal, dehydrated, v. ground shelled corn for lactating cows, Tex. 233.  
 meal v. shelled corn, U.S.D.A. 662.  
 N and K top dressings for, Ga.Coastal Plain 179.  
 plant production, electricity in, 39.  
 planting tests, Ga. 772.  
 pox control, N.J. 645.  
 preservation for industrial use, 316.  
 production for starch, problems, 317.  
 production machinery, 839.  
 ratios of organic to nonorganic N with, Ga. Coastal Plain 179.  
 seed and sprout treatment with Spergon, U.S.D.A. 788.  
 seed roots, nematodes in, hot-water treatment, 497.

## Sweetpotato (es)—Continued.

size of seed, date of planting, spacing, etc., Tex. 180.

soft rots, prevention during storage, N.J. 795.

use as feed, U.S.D.A. 723.

variety tests, Ga. 772, Miss. 467, P.R.U. 31, Tex. 180.

work of regional research laboratories on, U.S.D.A. 723.

Sweet-william *Fusarium* wilt, 350, N.J. 801.

Swine—see also Pig(s) and Sows.

diseases due to nutritive deficiencies, 390.

erysipelas, phases of, Nebr. 87.

erysipelas, sectional incidence in United States, 252.

erysipelas, studies, U.S.D.A. 676.

influenza, virus, mice immune to, strain specificity of complement fixation with sera of, 245.

physiological relations of parturition, relation to reproductiveness, 611.

pregnancy diagnosis in, 771.

true lateral hermaphroditism in, 313.

type in, U.S.D.A. 662.

*Syllepta derogata*, new braconid parasites of, 514.

*Symphylellopsis* n.spp., description, 807.

*Syngamus trachea* in robins and chickens, 391.

*Systena blanda*, see Flea beetle, pale-striped.

*Tabanus sulcifrons*, mechanical transmission of bovine anaplasmosis by, 89.

*Tachinomys* spp., with descriptions of new ones, 811.

*Tacnia pistiformis* larvae, resistance of rabbits to intestinal phase, 351.

*Tacnia tacniaciformis* larvae, cultivation in vitro, 384.

Taeniasis, experimental fowl, beetle supply in, 384.

*Taeniothrips simplex*, see Gladiolus thrips.

Tamarisk—

adaptability as fine cabinet wood, Ariz. 199.

fence post, creosoted, studies, Ariz. 199.

Tannin, canaigre for, Tex. 180.

Tanning materials, work of regional research laboratories on, U.S.D.A. 723.

Tapeworm(s)—

cultivation in artificial media, 213.

fringed, in lambs, Colo. 676.

in lambs, treatment with lead arsenate, 532.

in young robin, 391.

infestation, effect on chickens, N.C. 87.

new dilepidid, from a cardinal, 254.

of chicken, removal by host starvation, 828.

rate of growth, 213.

Taphrina—

*deformans*, diurnal cycle of ascus maturation, 59.

genus in North America, studies, 489.

Tar oil winter washes, specifications and methods of analysis, 215.

Taro diseases and control, Hawaii 57.

Taro, processing and uses, Hawaii 14.

*Tarsonemus laticarpus*, see Bulb scale mite.

Tax(es)—

delinquency, Mich. 103

delinquency, farm, in South Carolina,

nature and extent, S.C. 818.

farm, and cost of public services, rela-

tion to land resources, Iowa 403.

farmer's, new and old, 544.

relief program of State, benefits to farm

owners from, N.C. 101.

Taxation revenues, collection and expendi-

ture, in Texas, Tex. 256.

Tea agreement, international, voluntary re-

strictions and agreements U.S.D.A. 105

Tea, effect on energy metabolism of children,

Tex. 267.

Tea regulation, U.S.D.A. 105.

Teeth—

decay, and diastatic activity of saliva,

864.

decay, and nutrition in London ele-

mentary school children, 863.

human, growth pattern, 706.

incisor, hereditary absence in rats, 613.

molar, of rat, development, 557.

mottled enamel in, types, 559.

Temperature(s)—see also Climate.

and life, 739.

and rainfall of Kansas, trends in, 739

annual march, at Washington, D. C.,

445.

atmospheric, variations with altitude

in United States, 445.

changes, solar-constant and atmos-

pheric, 739.

forecasting minimum for Florida, for-

mula, 739.

graph for geographer, new type, 295.

thermionic control, 758.

Tennessee Station, notes, 432, 878.

Tent caterpillar, forest, outbreaks in northern

Minnesota, Minn. 511.

Tenure groups, progress, 400.

Teosinte production tests, Tex. 180.

*Tephrosia*, insecticides from, 215.

Termite(s)—

attacking books and papers, 217.

control, Conn.[New Haven] 65.

damage in South Africa, 353.

desert, injury to native range grasses,

Tex. 214.

dry wood, resistance of material to,

P.R.U. 66.

living, study, laboratory technique for, 509.

Terpene series, unsaturation in, determina-

tion, 728.

Terpene-yielding species of Lauraceae in

northern Brazil, 752.

Terrace—

construction, equipment for, 688.

dimension changes and movement of ter-

race ridges, 392, U.S.D.A. 157.

outlets, bituminous channel linings for,

Wis. 736.

system planning to reduce point rows,

837.

Terraced lands, outlet design for, 837.

## Testes—

- degeneration incident to cryptorchidism, effect of anterior pituitary-like substance, 30.
- of prepuberal rat, effect of large amounts of androgen, 30.

## Testosterone—

- injected into caponized fowls, effectiveness, relation to vitamin E, 463.
- propionate—
  - and related substances, absorption of pellets implanted in rat, 29.
  - effect on bone growth and skeletal maturation of rats, 463.
  - effect on reproduction in female, 30.
  - effect on responsive organs of immature rats, 615.
  - inactivation by female rats, 30.
  - response of preputial glands of female mouse to, 464.

## Tetranjchus—

- pacificus* relation to grapevine red leaf, 500.
- telarus*, see Red spider.

## Tetrastichus—

- bruchivorus*, description, 812.
- rugglesi*, parasite of cane borers, 71.

## Tettigidea parvipennis, genetic problems, 765.

## Tettigoniidae of Texas, 357.

## Texas Station—

- bulletins and other publications, abstracts, 287.
- notes, 878.
- report, 287.

## Textile(s)—see also Fabrics.

- advertising, claims found false or misleading by Federal Trade Commission, 140.
- analysis, use of microscope in, 280.
- dyed, fading by radiant energy, 284.
- fabrics, relation to dry cleaning, 285.
- fiber atlas, 280.
- finishes, evolution of, 283.
- finishes, water resisting, evaluation, 284.
- finishing treatments, technical evaluation, 283.
- labeling, informative, 139, 140.

## Thamnotettix argentata, vector of tobacco yellow dwarf, 510.

## Theileria parva transmission by ticks, 815.

## Thermobia domestica, see Firebrat.

## Thermoperiodism, proposed use of term, 758.

Thiamin—see also Vitamin B<sub>1</sub>.

- activation of coocarboxylase by, 710.
- chloride, bibliography of, 423, 708.
- content of vital fluids, coocarboxylase determinations as index, 861.
- deficiency—
  - and urinary pyruvate, 868.
  - avian, characteristic symptoms and pathogenesis, 535.
  - avian, pathology and clinical behavior, 535.
  - in man, effect, 278.
  - in wheat flour and fortification with synthetic thiamin, 709.

## Thiamin—Continued.

- deficient pigeons, recovery of virus morphologically identical with psittacosis from, 678.
- distribution in rice grain, 562.
- effect on fermentation of yeast, 303.
- excretion, studies, 132.
- in bread, loss on baking and toasting, 709.
- in cereals, stability, effect of long cooking, 132.
- in foods, effect of processing, 563.
- in whole wheat and clear flours, 708.
- polarographic determination, 10.
- pyrimidine analog of, and growth, 452.
- sparing action on body tissue catabolism, 426.
- urinary excretion at varying levels of intake, 711.
- urinary excretion, in children, 868.
- values of wheat-germ muffins, 132.
- Thiazole effect on *Phycomyces*, 452.
- Thiazolidine-4-carboxylic acid, protein hydrolysis in presence of, Minn. 726.
- Thiobacillus thiooxidans*, metabolism and mechanism of action on sulfur, Wis. 791.
- Thistle(s)—
  - Canada, control implements for, Ind. 97.
  - crown fly on artichoke, Calif. 507.
  - in North Dakota, N.Dak. 623.
- Thorn-headed worm—
  - eggs in swine, survival on soil, 383.
  - of swine, variability of eggs, 832.
- Thrips—
  - injury of peanut seedlings, U.S.D.A., 336, 357.
  - on seedling cotton, 352.
- Thrips tabaci*, see Onion thrips.
- Thrombin and prothrombin, coexisting, stability, 582.
- Thymus extract, treatment of successive generations of rats with, 467.
- Thyroid(s)—
  - chick, strain difference in responsiveness to thyrotropin, 467.
  - gland of frog, histological differentiation, correlation with beginning of function, 420.
  - relation to thymus and to gonadotropic hormones, Colo. 610.
- Thyroidectomy of young male goats, effect on AP hormones, 670.
- Thyrotropic hormone in rabbit pituitary during growth, 670.
- Thyrotropin, bio-assay of, 467.
- Thyroxine, effect on hereditary dwarf mice, 32.
- Tick(s)—
  - and relapsing fever spirochetes in Utah, 815.
  - cattle, in wild animals, examination for, 865.
  - eradication, U.S.D.A. 676.
  - from British Columbia, 815.
  - Gulf coast, relation to screwworm infestation in livestock and control, Tex. 243.

- Tillage tools causing compression and arch formation, physical reactions of, Ala. 688.

Tocopherol,  $\alpha$ —see also Vitamin E.

- bibliography, revision, 428.
- minimum requirement of rabbits, 664.
- related compounds, vitamin E activities of, 428.

## Tomato (es)—

- Alternaria solani* defoliation disease, control, Conn.[New Haven] 51.
- ascorbic acid in, factors affecting, Ga. 854.
- bacterial canker, control methods, Utah 209.
- Bacterium vesicatorium* (*Phytophthora vesicatoria*) spot infection on, Ind. 51.
- breeding, Miss. 776, Nchr. 42, N.H. 326, Tex. 189, U.S.D.A. 776.
- bushy stunt virus, chemical properties, 202.
- canned, quality, sold in State, Ind. 103.
- canned whole, calcium firming of, 551.
- colchicine-induced homozygous, through doubling clonal haploids, 26.
- cost of production, P.R.U. 104.
- crosses, hybrid vigor in, 191.
- crown gall, hyperauxin in, 498.
- culture, nitrogen in, efficient use, 625.
- culture tests, Ga. 776.
- curly top control methods, 647.

## Tomato (es)—Continued.

- curly top control, relation to plant populations, 200.
- drip n.-off of seedlings, relation to light, Tex. 202.
- deficient diploid, parthenocarpy in, 459.
- direct seeding v. southern-grown plants, 192.
- disease(s)—
  - control, 489.
  - control in northeastern Brazil, 647.
  - control, new developments, 708.
  - in Norfolk area and on Eastern Shore, U.S.D.A., 201.
  - in south Texas, U.S.D.A. 788.
  - new, of unknown cause, U.S.D.A. 788.
  - new to Ontario, 499.
  - studies, Ga Coastal Plain 201, Tex. 202, U.S.D.A. 50.
- early blight, Ga.Coastal Plain 201, U.S.D.A. 50.
- effect of boron on pollen germination and pollen tube growth, 306.
- effect of staking and pruning, Conn.[New Haven] 41.
- effect of supplemental nitrogen applied during growing period, Conn.[New Haven] 41.
- fertilizer tests, Ga. 776, Miss. 776, Ohio 189.
- foot rot due to *Phytophthora cryptogea*, 59.
- fruitworm—
  - control, dust preparations for, Miss. 811.
  - numbers captured at light traps, 75.
  - studies, Ga. 806, Tex. 214.
- Fusarium* wilt and defoliation diseases, resistance to, Ind. 51.
- gray spot, U.S.D.A. 336.
- greenhouse production, effect of growth-promoting substances, Mich. 43.
- grouping of strains by use of Latin square, 624.
- haploid, diploid, and tetraploid genotypes in, genetic stability, 459.
- hereditary variegation associated with sterility, 750.
- heterosis in, as determined by yield, 191.
- hybrid vigor in, 42.
- improvement, N.Y.State 477.
- juice, mold count as index to quality, 209.
- leaf blight control, N.Y.State 490.
- leaf mold in field in New Hampshire, U.S.D.A. 788.
- lightning injury to, 847, N.J. 202.
- Macrosporium* blight and stem canker control, Ga. 789.
- marketing on grade basis, Ind. 103.
- marketing, to processors on grades, Ohio, 261.
- methyl bromide fumigation, Hawaii 190.
- molds in markets, 639.
- necrosis, component of severe streak, 59.

## Tomato(es)—Continued.

- normal seeded and parthenocarpic fruits, differences, 755.
- physiological study, growth and fruiting, 779.
- pinworm, in California, 220.
- plants—
  - diseased, late-set, and variously fertilized, defoliation, Ind. 51.
  - direct-seed v. transplanted, diseases in, Ind. 51.
  - foliar diagnosis with symptoms of streak disease, 499.
  - grown in special medium, formation of  $\beta$ -2,2,2-trichloroethyl-gentiobioside, 166.
  - mosaic-infected and normal, comparative characteristics of protein, 200.
  - two v. one per stake, 625.
- production, boron and manganese in, 479.
- pruning and training, 325.
- psyllid infestation, effect of treatments for on spoilage in storage, Colo. 651.
- quality, factors affecting, Ind. 42.
- response to varying concentrations of nutrient cultures, 329.
- riboflavin content, 869.
- root(s)—
  - excised, growth in agar culture, effect of vitamin B<sub>9</sub>, 603.
  - excised, growth and heterosis in, 20.
  - nematode, Ind. 65.
- rosette, proposed name, U.S.D.A. 788.
- scion, atropine transference from jimson weed stock to, 753.
- seed production, Ind. 42.
- germination, inhibiting action of blue light on, 308.
- Septoriosiis, 847.
- severe streak, a composite virus disease in New Zealand, 59.
- shape index, charts for computation, 41.
- size inheritance in fruits, 609.
- spacing and pruning tests, Miss. 776.
- spacing and training, Miss. 477.
- spotted wilt control, 798.
- storage studies, effects of altered internal atmosphere, 779.
- transplanting, nutrient solutions and vitamin B for, effect, 192.
- varieties, Miss. 477.
- varieties, fertilizers, and culture, Ga. Coastal Plain 188.
- varieties for canning, 5-yr. yield record, N.Y.State 626.
- varieties, yields, Miss. 776.
- variety tests, Miss. 776, Nebr. 42.
- Verticillium* wilt-resistant varieties, need for, Utah 499.
- virus diseases, control, 637.
- waxing experiments, 44.
- wilt, inheritance of resistance to, 490.
- wilt outbreak, P.R.U. 51.
- wilt-resistant new variety, Pan America, U.S.D.A. 43.

## Tomato(es)—Continued.

- worm, numbers captured at light traps, 75.
- yield and composition, effect of calcium and potassium, 479.
- Tortricid larvae on artichoke, Calif. 507.
- Totaquina production in Philippines and *Cinchona* culture, 781.
- Toxemia among cattle of Gulf coast area, Tex. 213.
- Toximeter, insect, specifications, plans, and use, N.H. 508.
- Toxoptera graminum*, see Green bug.
- Trachelus tabidus*, see Sawfly, black grain stem.
- Tractor(s)—
  - fuel, power alcohol for, 838.
  - on small farms, Ohio 540.
  - stop hitches, 839.
  - work, costs of, 402.
- Trade agreement, Argentine-United States, background and concessions, U.S.D.A. 692.
- Trade unions in agriculture, 550.
- Trailer, two-wheeled, rubber-tired, homemade, description, S.Dak. 100.
- Transpiration—
  - and apparent photosynthesis of young apple trees, effect of excess water in soil, 193.
  - and evaporation, U.S.D.A. 294.
  - and photosynthesis, method for studying simultaneously, 162.
  - effect of osmotic concentration and cell permeability, 450.
  - of apple leaves, effect of soil moisture, 329.
  - of apple trees, effect of oxygen and carbon dioxide in soil atmosphere, 482.
  - of pecan leaves, effect of downy spot, 503.
  - rate of bean leaves, relation to stomatal frequency, 758.
  - rate of grasses, field method for estimating, 605.
  - rate of plants, continuous estimation, 306.
- Tree(s)—
  - coniferous, see Conifer(s).
  - deciduous, effects of spray oils on, 654.
  - diseases, 211.
  - diseases, reducing losses from, in eastern forests and farm woodlands, U.S.D.A. 802.
  - forest, economic injury by gypsy moth, 487.
  - forest, species hybrids in. 312.
  - hardwood, effects of incomplete girdling, 785.
  - hardwood, natural reproduction, effect of furrowing, Ohio 198.
  - infections, method of making, 328.
  - injured by blizzard, pruning and handling, 326.
  - native, of Georgia, 450.
  - of Indiana, annual tree-ring formation, relation to rainfall, 445.
  - ornamental, for New Mexico, N.Mex. 634.
  - propagation by cuttings, Mass. 102.

- Tree(s)—Continued.  
 ring analysis and dating in Mississippi drainage, 295.  
 rings and climate, 591.  
 roots, effect on morphological characteristics of soil profiles, 593.  
 shade and ornamental, maintenance, 785.  
 shade, diseases and other disturbances, 802.  
 shelterbelt, *see* Shelterbelt(s).  
 suitable for prairie-plains, nursery practice for, U.S.D.A. 197.  
 treatment for root rot, Tex. 201.  
 wayside, of Malaya, 600.
- Trefoil, birdsfoot and big, characteristics, U.S.D.A. 621.
- Tribolium confusum*, *Gnathocerus cornutus*, and *Trogoderma versicolor*, competition in populations of, 513.
- Trichina larvae in pigs, precipitate formation around, 827.
- Trichinella spiralis*—  
 culturing in vitro, 384.  
 embryonic development, effect of X-rays, 384.  
 immunity, attempted passive transfer to rats and mice, 828.  
 in garbage-fed hogs in San Francisco, 683.  
 in vitro action of immune serum on, 88  
 infections, effect of host vitamin E deficiency, 384.  
 intestinal resistance to second infection, 828.  
 larvae in vitro, effect of immune serum, 828.  
 recovered from rats, effect of host age, 828.  
 susceptibility of gophers to, 805.  
 $\beta$ -2,2,2-trichloroethylgentiobioside—  
 formation in tomato plants in special media, 166.  
 synthesis by gladiolus corms, 167.
- Trichidectes ovis*, control, Ga. 831.
- Trichoderma*, mold toxins in, 338.
- Trichogramma*—  
 and oriental fruit moth, 64.  
*minutum* for control of sugarcane borer, P.R.U. 66.
- Trichomonas fetus*—  
 in Wisconsin cattle, 827.  
 infection, instrument for diagnosis and treatment, 387.  
 reactions to environmental changes in bacteria-free cultures, 678.
- Trifolium fragiferum*, new immigrant to North America, 600.
- Tripacum*, *Euchlaena*, and corn, genetic and cytological relations, Tex. 180.
- Triticum timopheevi*, disease resistance of, transferred to common winter wheat, 342.
- Trogoderma versicolor*, *Gnathocerus cornutus*, and *Tribolium confusum*, competition in populations of, 513.
- Trout disease, furunculosis, control, Wis. 806.
- Truck crop(s)—  
 acreages, production, price, etc., Del. 256.
- Truck crop(s)—Continued.  
 insects, studies, Tex. 213.
- Truck farming, economic study, Miss. 404.
- Trypanca* spp., studies, 812.
- Trypanosoma*—  
*duitoni* infection in mice, protective action of sheep serum against, 828.  
*equiperidum* cultivation in yolk sac of developing chick embryo, 678.  
*evansi*, passage through goat, effect, 387.  
*vivax* infection of cattle in Panama, 387.
- Tryptophan—  
 effectiveness as growth regulator, 165.  
 requirement of chick, 606.
- Tuberculin(s)—  
 and other diagnostic tests, U.S.D.A. 676.  
 low-potency, use, Wis. 827.  
 protein, removal of impurities, nucleic acid, and polysaccharide from, 440.  
 test, avian, and its specificity, 247.
- Tuberculosis—  
 campaign, attainment of goal, U.S.D.A. 827.  
 in buffalo, 830.  
 of cattle, eradication, effects on human health, 830.  
 studies, U.S.D.A. 676.
- Tularemia in dogs, 252, 534.
- Tulip(s)—  
*Botrytis* blight, Conn. [New Haven] 51.  
 current-season development of virus symptoms in, 60.  
 fire, disease new to Argentina, 649.  
 in Argentina, *Botrytis tulipae* on, 503.  
 mosaic, U.S.D.A. 201.  
 triploid, megagametophyte development in, 765.
- Tuliptree—  
 fertilizer trials for improved establishment, 335.  
 seed production in, 487.
- Tumor(s)—  
 connective tissue, of horses and mules, 533.  
 tissues, bacteria-free, crown gall production by, 630.  
 transmissible lymphoid, of chicken, 538.
- Tung oil production in China and its future, 784.
- Tung tree(s)—  
 adaptation of, Ga.Coastal Plain 188.  
*Cercospora* leaf spot of, 61.  
 flowers, period of stigma receptivity in, 632.  
 nuts, germination, effect of planting date, 632.  
 one-year seedling, pruning and training, 334.  
 resistance to low temperature, 632.  
 seedling, effect of root knot, Ga.Coastal Plain 201.  
 selection of promising types, U.S.D.A. 776.  
 shoots and fruits, growth period, 632.  
 training and pruning studies, Miss. 784.

## Turf—

injuries in Minnesota, Minn. 792.

South African, relation to invertebrate pests, 216.

## Turkey(s)—

blood protozoan, transmitted by *Simulium nigroparvum*, 243.

breeders, new device for selection, 664.

breeders, reproductive performance, effect of restricted food intake, 232.

breeding of small market-type carcass, Ind. 76.

breeding, *Salmonella* infections, 243.

capons, N.Dak. 233.

carriers of *Haemaphysalis melagris*, 537.

concentrate feeding of, Wash. 819.

crossbreeding and heterosis in, 461.

curing and smoking, 373.

egg production and hatchability, effect of vitamin D level, 372.

eggs, artificial light for stimulating hatching, Ind. 76.

embryonic development, 315.

fattening, U.S.D.A. 662.

feeding, N.Dak. 233.

feeding and confinement rearing experiment, Mich. 668.

green feed for, Colo. 662.

limited range for, 517.

marketing, Tex. 256.

paratyphoid infection of, 97.

pendulous crop in, treatment, Utah 254.

poults—  
biotin and prevention of dermatitis in, 668.

from hens fed different levels of vitamin D, response to, 518.

growth on simplified diets, 517.

poisoning from milkweed, 518.

protein utilization by, 517.

salt tolerance, N.Dak. 373.

research in Oklahoma, 519.

riboflavin requirement for hatchability, 517.

sex ratio and mortality in, 315.

starting and growing rations for, Ind. 76.

vitamin D and reproduction in, Colo. 662.

yellow corn v. sunflower seed for, Nebr. 76.

## Turnip—

aphid, studies, Tex. 214.

greens, ascorbic acid and minerals in, effect of environment, Ga. 854.

greens, Ca and P composition, Miss. 443.

greens, mineral analyses, Tex. 189.

Tylenchidae without valvular median esophageal bulb, 650.

## Typhula—

genus, studies, 489.

*toana*, notes, Minn. 792.

*toana*, snowmold of turf due to, 204.

Tyrocidine, toxicological and pharmacological properties, 829.

Tyrothricin, toxicological and pharmacological properties, 829.

Udder tissues, irritant for, produced by mastitis streptococci in milk, 530.

## Ultraviolet—

irradiation of poultry and cattle, effect, 842.

light fluorescence, method of identifying potato tubers free from decay, 496.

Umbrella pine, propagation by hormone-treated cuttings, 49.

Underwear, cotton and rayon knit, selected types, serviceability, U.S.D.A. 716.

Undulant fever, clinical and subclinical, 247.

Unemployment in United States, papers on, 399.

## U. S. Department of Agriculture—

Bureau of Agricultural Chemistry and Engineering, see Bureau of Agricultural Chemistry and Engineering.

Bureau of Agricultural Economics, see Bureau of Agricultural Economics.

Bureau of Animal Industry, see Bureau of Animal Industry.

Bureau of Dairy Industry, see Bureau of Dairy Industry.

civil-service employment in, U.S.D.A. 143.

historical sketch, 572.

laws applicable to, U.S.D.A. 572.

Office of Experiment Stations, see Office of Experiment Stations.

publications, list, 287.

report of Secretary, 876.

Soil Conservation Service, see Soil Conservation Service.

Weather Bureau, see Weather Bureau.

yearbook, 293, 400.

Upholstery, survey of State laws and judicial decisions on, U.S.D.A. 717.

Urban life, measuring attitude toward, 263.

## Urea—

inhibiting effect on microbiological assay of riboflavin, 869.

nitrogen utilization by growing chicks, 666.

use for maintenance and growth, 77.

utilization as source of nitrogen by ruminants, Wis. 820.

utilization, effect of level of protein in ration, 375, Wis. 820.

Uredinales of New Guinea, 752.

Uric acid, blood, of zinc deficient rats on various diets, 126.

## Urinary—

calculi in -

calves, U.S.D.A. 676.

feeder lambs, Colo. 676.

steers, relation to milo grain, Tex. 225.

excretion of pyridoxin, 713.

protein, analyses, 440.

## Urine—

cow, as fertilizer for bluegrass pasture, 233.

human, nicotinic acid derivatives in, 712.

minute amounts of lead in, determination, 534.

## Urine—Continued.

nicotinic acid in, determination, clinical method, 735.

vitamin B<sub>1</sub> in, determination, 9, 152, 710.

*Uromyces lespedezae-procumbentis* in Japan, 642.

*Ustilago*—

*bullata* on grasses, 493.

spp. crosses, inheritance of sorus characters in, 457.

*zeae*, pathogenicity of paired haploid lines v. mixed haploids, 310.

Utah Station, notes, 432.

*Vaccinium*, species and varieties, chromosome numbers of, 27.

*Valonia ventricosa*, effect of light on, e. m. f. of, 454.

Vanadium, effect on plant growth, 19.

*Yanessa (Cynthia) cardui*, see Painted lady.

Vanilla production and trade of Mexico, U.S.D.A. 692.

Variables, determining which of two is better for predicting a third, Mich. 615.

Vedalia, maintaining supply of, P.R.U. 65.

## Vegetable(s)—

and climate, U.S.D.A. 294.

boron requirements, N.H. 326.

Breeding Laboratory, Regional, progress at, U.S.D.A. 777.

carotenoid pigments, Ind. 6.

chemical studies, U.S.D.A. 723.

conserving minerals and vitamins, Miss. 414.

crops, disease resistance in, 208.

curly top-resistant, breeding, U.S.D.A. 776.

## disease(s)—

and disease surveys, N.Y.State 490.

control 646.

handbook, 796.

in greenhouse, control, 59.

in Oregon, U.S.D.A. 336.

in south Texas, U.S.D.A. 788.

notes, Conn.[New Haven] 50.

on New York market, U.S.D.A. 788.

disintegration of cell membrane materials during cooking, 551.

dried, vitamin retention by, 560.

effect of growth substances on, 777.

effect of vitamin B<sub>1</sub> on yield, 777.

fall preparation of seedbeds for, advantages, Miss. 477.

fats, see Fats.

fertilizer requirements, N.Y.State 477.

fertilizer tests, Tex. 189.

freezing preservation, 552.

fresh, mineral losses in washing for cooking, 269.

green, pure carotene in, determination, 441.

growers price troubles, Miss. 572.

growth and yield, effect of partial defoliation at transplanting time, 477.

homogenized, in diet of young infant, 701.

insects, N.Y.State 506.

## Vegetable(s)—Continued.

irrigation and mulching, Nebr. 42.

juices, processing, N.Y.State 550.

leaf, nitrogen needs, Miss. 477.

market diseases of, U.S.D.A. 796.

maturity of, determination, N.Y.State 435.

mineral composition, from different areas, effect on nutritive value, Tex. 267.

mycostatic salts to prevent mold growths on, 514.

oils, see Oil(s)

on sandy soil, organic matter requirements, Ind. 42.

on sandy soil, production and marketing, Ind. 42.

pigmented, and their juices, ascorbic acid in, 566.

preservation by commercial dehydration, U.S.D.A. 155.

production, soil management for, Conn. [New Haven] 16.

propagation and breeding, Tex. 189.

quality, determination, 269.

retailing, in New York City 261.

seeds, storage, effect of type of, 41.

significance of chloride nutrition for, 757.

use of liquid fertilizers for, 299.

varieties, Ga.Coastal Plain 188.

varieties, desirable for freezing and treatment to conserve ascorbic acid, 878.

variety tests, N.H. 326, Tex. 189.

wastes, work of regional research laboratories on, U.S.D.A. 723.

## Vegetation—see also Plant(s).

and mountain floods, 592.

counts on ranges, Tex. 181.

of Bolivia, 752.

of Ecuador, 752.

of Guianas, 752.

of Honduras, 752.

of Lesser Antilles, 752.

of Peru, 752.

of province of Santa Fe, Argentina, 751.

of Uruguay, 752.

Velvetbeans, variety tests, Ga.Coastal Plain 179.

*Venturia inaequalis*, genetic studies, pathogenicity and nature of salination in, 312.

Vermont Station, notes, 720.

Vermont Station, report, 430.

Vermont University, notes, 720.

## Vernalization—

and photoperiodic induction in ryegrass, 22.

effect on synthetic ability of plants, 758.

of long- and short-day plants by high and low temperatures and light, Ind. 20.

Vertebrates, Philippine, trematode parasites of, 539.

*Verticillium*—

*albotruncum*, monosporic culture, saltants from, 389.

*Verticillium*—Continued.

- alboatrum* on potato in Rheingau, 794.
- wilt of strawflower, 349.
- wilt of sugar beet, 636.
- wilt-resistant chrysanthemums, 801.

## Vetch—

- bruchid, new chalcidoid parasite, 812.
- bruchid, tests of species and varieties resistant to, U.S.D.A. 71.
- diseases, breeding and selection, Ga. 789.
- hairy, v. crimson clover as soil-conserving crop, Ala. 593.
- value of dolomite on, Miss. 317.

Veterinary—*see also* Animal diseases.  
medicine, progress in, 244.  
research and public health, 244.*Vibrio fetus*—

- infection, failure to carry over in ewes, 93.
- studies, 681.

## Village demography, aspects of, 411.

## Vine weevil, black—

- control, Conn.[New Haven] 65.
- in southern California, 64.

## Vineyards, soil moisture in, effect of cultural treatments, Nebr. 42.

## Vinylite resin corrosion preparations, use in study of organs of fowl affected with leucosis complex, 243.

## Vinyon, structure, properties, and uses, 282.

## Violets, genetic studies, Vt. 312.

## Virginia Station, notes, 432.

## Virus(es)—

- animal and plant, special research, U.S. D.A. 723.
- antagonism, natural host resistance, and acquired immunity, concept, 337.
- chemical properties, 202.
- disease, studies, 528.
- egg-cultivated, use for immunization, Ill. 88.
- inactivator from yeast, 200.
- purified, study with electron microscope, 488.
- serum control, U.S.D.A. 676.

## Viscose fabrics, effect of light and heat on breaking strength, color, and copper number, 138.

## Vitamin A—

- absorption and retention by hens on low-fat ration, 231.
- analysis, Ind. 6.
- blood level in rat, relation to vitamin A intake and to liver storage, 562.

## a. deficiency—

- and *Brucella* infection, relation, 527.
- clinical studies, 276.
- human and dark adaptation, 562.
- in ruminants, 242, 679.
- in silver foxes, 368.
- pathology of bovine kidney in, 89.
- relative overgrowth of central nervous system in rats, 277.
- simple visual test for, 129.
- terminal cerebrospinal fluid pressure values in, 679.

## Vitamin A—Continued.

- deficient rations of cow, ocular changes and other results of, 522.
- destruction by certain feeds, 817.
- destruction by meat scrap, Tex. 226.
- effect on calf scours, 521.
- effect on hypervitaminoses D<sub>2</sub> and D<sub>3</sub> in dogs, 229.
- for dairy cattle, shark-liver oil as source, Wis. 820.

*Xylaria*—

- apiculata* on potato in Florida, 207.
- longana* isolated from dying ginkgo branches, 649.

*Yams*—

- staking test, P.R.U. 34.
- variety tests, P.R.U. 34.

*Yantia* variety tests, P.R.U. 34.*Yeast(s)*—

- associated with insect species, 506.
- coenzyme I from, preparation, 582.
- cultures, auxin production by, 756.
- extracts, antianemic and antidermatitic action, 279.
- fermentation, effect of thiamin on, 303.
- in fermented food products, N.Y.State 550.
- insoluble polysaccharide from, molecular constitution, 581.
- monograph, 24.
- p*-aminobenzoic acid isolation from, 581.
- physiological properties, effects of heat and ultraviolet light, 758.
- strains, adaptive enzymes, 303.
- virus inactivator from, 207.

*Youth*—

- problems, Colo. 696.
- responsibility for building communities, 698.
- rural, of Ohio, education, family and community life, and employment and occupations, 261.
- survey, rural, of Virginia, Va. 699.

*Zabala*, the, P.R.U. 287.*Zephyranthes*—

- spp., chromosome determinations, Tex. 189.
- texana*, alkaloids and toxicity to *Phymatotrichum omnivorum*, 793.

*Zinc*—

- deficiency, acute dietary, in rat, effects, 273.
- deficiency in peaches and plums, control, 59.
- determination in plant materials, 8.
- effect on yields of peanuts, N.C. 34.
- in fertilizers, spectrochemical analysis, 732.
- sparing action of fat, tests, 126.

*Zoology*, medical and veterinary, index-catalog, U.S.D.A. 526.
